It is commonly assumed that, for a small initial value of y the method of successive approximation is applicable, the proviso being sometimes made that the value of y, so obtained be also small This assumption is shown in the paper to be not necessarily correct or in certain cases to lead to a rapid approximation when correct —List of Natal plants J Medley **Wood**

SCIENCE AND TECHNOLOGY OF PAPER.

Paper Technology. An Elementary Manual on the Manufacture, Physical Qualities, and Chemical Constituents of Paper and of Paper-making Fibres By R. W Sindall Pp. xv+253 (London Chas Griffin and Co, Ltd, 1906) Price 12s 6d. net

IN the author's preface it is stated that this work took shape in a course of lectures delivered at Exeter Hall in 1904-6 There is a suggestion here that "Exeter Hall" has extended its "mission" sphere to the paper-maker, but the impression is only momentary

As a matter of fact, the treatise is designed more expressly for the other side of the paper industry, the buyers and consumers, that is, it deals with paper from the point of view of the stationers, printers, bookbinders, and publishers; moreover, the treatment is severely material, strictly limited to "things" and to the exposition of their relations in accordance with the title and subtitle

The first page reveals the author's purpose and method, which are entirely practical There may be some who would question the "practical" qualifications of a technologist who gives prominence to the "ideal paper," which subject is treated in chapter 1 as a *résumé* of the discussion of the important section on chemical and physical constants.

We may clear away an ambiguity associated with this well-known adjective in relation to our subject The "practical paper-maker," as ordinarily so defined, limits his conduct and control of the processes which he superintends to sense impressions—what he can see—the appearance of the "stuff" in the beater or on the machine wire, what he can feel—the "handle" of the stuff in the beater or of the finished sheet, what he can hear—the hum of the beater roll as the measure of the distance from the bed-plate, and the beating work of his machine, what he can smell and taste are also taken as evidences of states and conditions of his material in process

The "practical" buyer judges a paper by the eye, the hand, the tongue—an excellent provider of a slightly alkaline fluid for testing "sizing" efficiency—the ear for "rattle"—and he avails himself also of the sixth sense, muscular sense, in measuring the mechanical properties of resistance to pulling or tearing strains

The technologist, on the other hand, sets out from the position that the actual phenomena which condition the qualities of the finished paper are mainly the invisible and intangible; they are molecular, and belong to the invisible region of the scientific imagination, and can, therefore, only be followed by the methods of science

If we substitute for "practical" the word *thorough*, the technologist may leave the empiric invested with his lesser qualifications, and appropriate the higher designation commensurate with his comprehensive survey of fundamental principles

The author's present contribution to the technical literature of paper-making is entirely in this spirit The second chapter, on "technical difficulties," enforces the useful moral of the relation of difficulty and the critical investigation of defects to progress The examples are well chosen, and it is easy to see that they represent actual working experiences

Following these preliminary chapters we have a brief account in successive chapters of paper-making processes, classified in the accepted order, rag papers, esparto and straw, wood pulp, and the miscellaneous group of packing papers and boards A feature of these chapters is the generalised summary of technical effects given in tabular form Thus on pp 48-9 is a tabulated outline of the processes involved in the preparation of half-stuff of the six leading types and grades, Table vi, p 51, is a comparison of times of beating in relation to half stuff and to quality of finished paper

Table ix, p 77, is a fitting conclusion to the section on wood pulp, giving the details of consumption of fibrous materials, fuel and water for providing the paper for a daily journal with a circulation of 200,000

It may be noted that one average conifer furnishes the pulp for 1000 copies of the average "daily," and the coal consumed is equal to the weight of the paper produced, and may, by the way, be taken to represent many times this weight of the products of antecedent forest growth Such tables occur throughout the book, and give an original impress to matter which otherwise treated would have the unrelieved character of "stock" information

The section on "art" papers is an original discussion of their qualities and *defects*, with indications of the lines of investigation along which progress may be made, to the much desired ideal printing surface, which shall not involve the sacrifice of those qualities in the body-paper conditioning permanence Our "art" papers are an interesting study in compromise, and our "imitation art" papers are still more interestingly artful The author treats them with respectful impatience

Upon this necessary groundwork the manual proceeds to develop the subject of physical, mechanical and chemical qualities and properties of papers, the methods of investigation adopted by the "expert," the numerical expression of the results, with a critical discussion of the value of the constants arrived at In this section the author devotes a chapter to a further *exposé* of the "C B S units," in which special attention is paid to the volume-composition of papers and to breaking strains reduced to the actual unit of sectional area of the paper These units have proved of value in practice, and their usefulness must be insisted upon, especially in educating the young technologist to associate with his tests mental pictures conformable with the actualities of paper In these respects the otherwise comprehensive unit of the "breaking length" adopted by the German pioneers in this branch of technology has been found wanting

In those sections devoted to paper testing, which make up more than half the volume, the author takes pains to make his exposition lucid. We note an occasional slip, as in dealing with the question of a coloured ash left on burning a paper "If blue, ultramarine, Prussian blue, or smalts may be present" This must be corrected as regards the cyanide blue Again —"the blue is tested by boiling with caustic soda and filtering" "The Prussian blue passes into solution" This inaccuracy will be evident to the chemist

In the section on the estimation of moisture we find the expression "bone dry" for "oven dried" Bones are not dry to the chemist, only to the poet

In the "dictionary of chemical terms" and the "glossary of various papers" which make up the concluding chapters we also note a number of slips, which perhaps may be explained by the laudable aim at short, crisp definitions, but this hardly excuses the description of caustic soda as "prepared by boiling carbonate of soda with quicklime", bleaching powder as a "dry *pulverulent powder* prepared by exposing dry powdered quicklime to chlorine gas"—the italics here are our "note of exclamation"; "dextrine" as industrially obtained "by the action of boiling dilute sulphuric acid on starch", "dicotyledon" as including the Coniferæ with angiosperms, such as beech and ash

These descriptive terminologies are excellent in plan, and generally useful They should be carefully revised, and perhaps amplified, in future editions. A section on bibliography would be a useful addition, and we think it is due from the author to acknowledge more fully the sources of much of the matter in this book, especially the German text-books and publications of which he fully avails himself The book is fully illustrated, and the matter thereby pointed and elucidated

It is evident that the work is one we can appreciatively commend to the very wide circle of those interested in "paper", as for the paper-makers, the author only indulges, with becoming modesty, the "hope that this book may prove useful to them" We think they will see the value of keeping pace with the critical knowledge of the consumers

WEIGHTS AND MEASURES

Outlines of the Evolution of Weights and Measures and the Metric System By Dr William Hallock and Herbert T Wade Pp xi+304 (New York The Macmillan Company, London Macmillan and Co, Ltd, 1906) Price 10s net

THE literature of weights and measures is very extensive, and, as a rule, singularly uninteresting Messrs Hallock and Wade are therefore to be congratulated on having produced a treatise on the subject which is at once instructing and attractive For this is an admirable piece of work, in which the result of much tedious research is presented in a bright and lucid narrative The first chapter is devoted to a brief review of the speculations of metrologists and antiquaries concerning the weights and measures of the ancients. It includes a particularly good account of the Babylonian units and the various theories respecting them which have been deduced from the Senkereh tablet and the scale of Gudea. After a rapid survey of the weights and measures of the Hebrews, the Greeks and the Romans, the authors pass on to consider the systems in vogue in Great Britain and in France from the earliest times up to the end of the eighteenth century. The next two chapters and the fifth deal with the origin and extension of the metric system. They trace the system from its embryonic stage in the writings of Mouton, Picard, Huygens, and Cassini, to its fully-elaborated form in the law of April 7, 1795. The geodetic work of Delambre and Méchain is next described, and the opportunity is taken to introduce short explanations of a trigonometrical survey and of the determination of latitude An account follows of the construction of the metric standards of the French Archives and of the lengthy interregnum of *mesures usuelles*

The meeting of the International Geodetic Association at Berlin in 1867 marks an important epoch in the history of the metric system The authors describe the influential part played by it in securing the establishment of the International Metric Commission. This leads to an interesting account of the International Committee of Weights and Measures and its bureau at Sèvres In this connection it may be mentioned that, owing to the death of the British representative early last year, this country is at present not represented on the International Committee The power of appointing a member to fill the vacancy rests with the committee itself In 1884 the committee had some difficulty in finding a suitable representative for this country owing to the fact that the officer in charge of our Standards Department at that time, although an official of standing, was comparatively unknown in the scientific world At the present time, now that all the metric prototypes have been distributed, and thus the most important object of the convention achieved, it is absolutely necessary in order that the United Kingdom may continue to derive any advantage from its contributions to the funds of the Metric Bureau, that the representative of this country on the committee should be an official of the Government department which is charged with the construction and preservation of the Imperial and metric standards It will accordingly, no doubt, be a matter of considerable satisfaction to the International Committee that the recently appointed Deputy Warden of the Standards is an eminent man of science, in every respect worthy of membership in that distinguished body which has included on its roll such names as Mendeléeff, Bertrand, Foerster, Mascart, Christie, and Michelson

In their fourth chapter Messrs Hallock and Wade have set themselves the congenial task of explaining the standards of weight and measure in vogue in their own country The desirability of a simple and uniform system of weights and measures [illegible]fully

realised at an early stage of the existence of the United States. Washington devoted much attention to this subject; and it was under his direction that in 1791 a committee of the Senate entered upon a very full consideration of the questions involved They reported in favour of a decimal system, and recommended the adoption of a standard of length divided into five equal parts, each of which would correspond to a foot. No legislative action was taken, however, to give effect to these recommendations In 1819 a committee of the House of Representatives submitted a report advocating that models of the yard, bushel, and pound, conforming to those in most common use, should be made and adopted as the standard weights and measures of the United States This proposal also proved abortive The elaborate report prepared in 1821 by Mr Secretary (afterwards President) Adams, a warm admirer of the metric system, was likewise without any immediate effect The metric system was not seriously considered in the United States until 1866, when the use of the system was authorised by Congress In 1889 copies of the international metric standards were distributed by the International Committee to the various States which were parties to the Metric Convention The copies received by the United States were immediately adopted as primary standards, and in 1893 a formal order of the Treasury Department recognised the international prototype metre and kilogram as fundamental standards, and directed that the customary units, the yard, and pound were to be derived therefrom

Chapters vi, vii, and viii deal with the advantages which would be derived from the universal employment of the metric system in commerce, manufactures, and medicine The authors admit having a bias in favour of this system, and they make out a very good case for its general adoption In the next chapter international electrical units are considered, and attention is directed to the benefits conferred upon electrical science by the introduction of the C G S system at the instance of the British Association The United States specifications for the practical application of the definitions of the ampere and volt were prepared by the National Academy of Science in 1895, in compliance with the provisions of an Act of Congress These specifications, which are quoted *in extenso* on pp. 211–215, differ in some slight respects from those prepared in this country about the same time by the Board of Trade

A most instructive chapter is the tenth, which relates to the construction and comparison of standards The various physical properties which should be possessed by primary standards are discussed, and an account is given of the different alloys which have been used in the construction of such standards The relative merits of line and end standards are next considered, the method of subdividing a scale by means of a dividing engine being well described It is mentioned that at the International Bureau the graduation of a metre into millimetres in this way occupies about sixteen hours The footnote on p 226 quoted from Guillaume appears to contradict the statement in the text respecting the accuracy attainable by this method.

A very good description is given of the comparators employed in the verification of standards of length, and the mode of using them is explained After some account of balances of precision, the British imperial standards of length and weight are described with illustrations The name of Mr Chaney, the late superintendent of weights and measures, is misspelt on p 247, and the position which he occupied is inaccurately designated as Warden of the Standards The latter office has been since 1878 an honorary adjunct to the permanent secretaryship of the Board of Trade

The chapter concludes with a simple and interesting explanation of measurement by means of wave-lengths of light This method was originally only applicable to the measurement of very short intervals, but Michelson has extended its application to lengths of any magnitude It is of great interest in metrology, since by making re-determinations from time to time positive testimony may be obtained as to whether any variation is taking place in the length of a standard At the present day the permanency of bronze standards of length is regarded with suspicion by metrologists The authors refer on p 219 to the fact that many of the bronze copies of the British yard which were distributed to various nations and scientific institutions in 1855 are believed to have since undergone changes in length due to molecular rearrangement This casts some doubt upon the invariability of the Imperial Standard Yard, which is made of the same material The recent developments of Michelson's method afford a ready means of deciding this important question

Some useful tables are appended, and a comprehensive index brings this well-conceived work to a close

---

ITALIAN SCIENTIFIC WORKS

I grandi Trafori Alpini By G B Biadego Vol i Pp xvi+1228, in addition to about 36 folded pages of tabular matter Vol ii 30 large folded plates (Milan Ulrico Hoepli) Price 45 lire (1l 16s)

Opere matematiche di Francesco Brioschi Vol iv Pp ix+418 (Milan Ulrico Hoepli, 1906) Price 1l

I Motori a Gas By Vittorio Calzavara Pp xxx+424 Manueli Hoepli (Milan Ulrico Hoepli, 1906) Price 4 50 lire

I Motori ad Esplosione, a Gas luce e Gas povero By Ing Fosco Laurenti Pp xii+361 Manueli Hoepli (Milan Ulrico Hoepli, 1906) Price 4 50 lire

THE opening of the Simplon tunnel amid a flourish of Italian trumpets was a fitting opportunity for the publication of a book dealing with this and other mountain borings That the author might have written a book on the Simplon tunnel alone is evidenced by the fact that the part he devotes to this tunnel occupies the space of an average-size volume

But he wisely points out that the Simplon is only one of a series of enterprises of the same kind, and while there have been improvements in the methods of working, as well as in the use of better explosives, the merit of originality belongs more properly to what is commonly known as the Mont Cenis tunnel Tourists to whom the name *Fréjus* represents a town on the Riviera will be somewhat surprised to find this tunnel described as the Galleria del Fréjus, which appears to be its correct name. In addition to this, the St Gothard, the Arlberg, and other well-known tunnels, the author describes several minor borings not commonly noticed by tourists, but which possess points of special interest; for example, one at Laveno, on Lago Maggiore The result is a volume of 1228 pages (excluding tables), and a second volume of plates, which form a striking contrast to the small Manueli Hoepli of the same publisher When we come to eighty pages of "Final Considerations," we cannot help being reminded of the typical interminable sermon of our early days, and the analogy is further increased by finding 115 pages of "appendix to the final considerations" to follow But all the same, the author cannot be accused of long-windedness There are a great many details connected with the boring of a tunnel, such as the rate of progress through different rocks, temperature conditions, descriptions of the machinery and of the accommodation for the workpeople, which interest not only the engineer, but also the general reader, and it cannot be said that the author has encumbered his subject with unimportant or uninteresting details to any appreciable extent The only exception we notice is that the tables of mean temperatures of such places as Venice, Alassio, and San Remo do not appear to have much bearing on the Simplon tunnel, under which heading they are tabulated The text would have been handier had it been bound in two volumes

From the same publisher we have the fourth volume of Brioschi's works, comprising mainly papers contributed to the Lincei Academy (1885–1896), the *Comptes rendus* (1858–1878), and miscellaneous journals, together with the preface and notes written for the Italian translation of Cayley's "Elliptic Functions" The papers for this volume have all been edited by Profs Francesco Gerbaldi and Ernest Pascal, and the volume is uniform in style with its predecessors In view of the rapid growth of mathematical literature, one cannot help wondering, however, if it is desirable to publish collected works in such an irreproachable style This reflection is suggested partly by the fact that though one or two English transactions have recently appeared with larger pages than formerly, they do not contain a corresponding increase in the number of words per page, though there is a great increase in their *weight* And it should be the object of the purchaser to obtain Brioschi's works, not merely to buy good paper and printing

The series of Manueli Hoepli, published in the form of pocket-books, numbered 900 volumes in April last Among the latest ones dealing with technical applications of science we have before us two books on gas engines, both written by authors living in Venice, and containing respectively 160 and 164 woodcuts. The objects of the books, as stated in the prefaces, are nearly identical Both authors point out that while other countries have advanced greatly in the study and construction of gas engines, the subject has received little attention in Italy Curiously enough, Signor Calzavara, who is a gas engineer, says less about the question of gas than Signor Laurenti The latter's book is divided into three parts, the first dealing with the combustibles (illuminating gas and heating gas, or "gas povero," as it is called in Italy), the second with gas generators, and the third with the gas engines themselves On the other hand, Signor Calzavara only devotes a single chapter to the gas question This chapter is, however, a long one, and it must be remembered that he has written several previous books on gas and gas motors

Other differences may be noted Thus Signor Calzavara gives a really full bibliography, while Signor Laurenti's book contains more numerical data in the form of tables Signor Laurenti goes into detail regarding cams, the other author only just refers to distributors without discussing the cam. Signor Calzavara considers that a "poor gas" engine, with its own generator, cannot be used efficiently for installations of less than 25 horse-power, Signor Laurenti fixes the limit at 15 horse-power These are the differences one would expect to find in two books written on the same subject by different authors, and they show that anyone interested in the subject would derive undoubted advantages from having both books for reference G H B

THE ATOMIC THEORY OF ELECTRICITY

The Electron Theory, a Popular Introduction to the New Theory of Electricity and Magnetism By E E Fournier d'Albe Pp. xxiii+311 (London Longmans, Green and Co, 1906) Price 5s. net

A GLANCE at the table of contents of this book is sufficient to show that it fills an acute want at the present time It attempts the consistent application of the all-embracing electron theory in an elementary manner to the whole range of electromagnetic phenomena In making this attempt, the author is to be congratulated both on the choice of his subject and the skill and originality he has displayed in accomplishing it It is a relief to find that the treatment, though popular, is to the point, and little or nothing is said of those vague and vast speculations as to the ultimate constitution of matter which have unfortunately become identified with the words "the electronic theory"

Few possess the necessary qualifications for a task which covers such a wide range of subjects, and, so far as we know, this is the first time it has been seriously attempted The book is therefore unique, and should prove of value to the student, the teacher, and the investigator. Although, no doubt, it would be possible to go through the work pointing out where a fuller treatment of the subject-matter would have been advantageous, this would hardly be fair in the present state of the science. We have rather to be grateful that a trustworthy guide,

to the theory in its existing state, has pointed the way to its wide application in a great many cases. As the author repeatedly points out, the logical consequences of the electronic theory are still very far from being worked out in many of the subjects dealt with, and this task offers a fine field of investigation, which may ultimately lead to new results of the highest practical importance

Probably nowhere is this more true than in the field of electrochemistry, of which, however, the treatment is somewhat superficial and unsatisfying Another topic, which fares even worse, and yet is one of which much might have been, and ultimately will be, made, is the optical activity of carbon compounds What little is said is so misleading, for example the last sentence of chapter xii, that it should be either omitted altogether or considerably amplified In the main, however, the treatment is refreshingly clear and interesting

Of course, it is to the explanation of that class of phenomena known as electromagnetic that the electron theory offers the greatest simplification Consider a phenomenon such as "the spark on break due to the extra E M F of self-induction," which is nothing but the electrical analogy of the water-hammer in a pipe when a cock is suddenly closed and the water stream stopped For water read electrons, and for pipe read conductor, and even a beginner gets a clear mental picture of the phenomena That all magnetic and electric phenomena are to be explained by definite motions and properties of the individual electron is a simplification that may be expected to ameliorate the lot of the future student considerably The electron theory provides for electricity that clear mental image of the processes involved, without which physical theories stagnate and become metaphysical Nevertheless, the faculty of being able to think in more than one system is not easily acquired, and it is doubtful, for example in magnetism, if anyone trained on the present systems will ever really abandon them

In addition to the topics already alluded to, chapters are devoted to the electronic treatment of thermo-electricity, the Hall and allied effects, optical phenomena, the Zeeman effect, radiation, voltaic electricity, radio-activity, and the electric discharge One chapter is devoted to a speculative effort, bold and imaginative, but logical, well considered, and unexceptionable, on the similarity of the infinitely great phenomena of the cosmos with the infinitely small of the electronic universe Finally, a new system of electrical quantities is advocated, in which electricity, represented by E, ranks as a fundamental quantity with length, mass, and time The author uses throughout the expressions "company of electrons," "army of electrons," to represent respectively the E S unit (2930 million) and the coulomb (8 79 trillions), and thus once for all reduces electric quantities to a definite *number* of electrons

Different readers will no doubt derive most benefit from different chapters according to their individual knowledge of the subjects referred to, but the book may be recommended to all interested in the progress of physical science Dr G. Johnstone Stoney, whose portrait appears as a frontispiece, contributes a preface to the work. F S

OUR BOOK SHELF

Manual of the New Zealand Flora By T F. Cheeseman Pp xxxvi+1199 Published under the authority of the New Zealand Government (Wellington J Mackay, 1906)

THE number of botanists who have contributed towards a knowledge of the New Zealand flora during the last forty years is remarkable, especially when it is recognised that their labours followed on discoveries made by earlier explorers and collectors of eminent repute Banks and Solander, Colenso, Sinclair, and Hooker are a few of the early botanists whose work was collated in the "Handbook of the New Zealand Flora," compiled by Sir Joseph Hooker and published in 1864 Since that date, besides Colenso, Thomas Kirk stands out prominently as an energetic collector and author, he collected not only throughout both the main islands, but also visited several of the adjacent groups Owing to his extensive acquaintance with the subject, in 1894 he was commissioned by the Government to prepare a flora of New Zealand, but the work was only half completed at the time of his death three years later The task was subsequently entrusted in 1901 to Mr Cheeseman, who has contributed numerous papers on new species, on the floras of Three Kings and Kermadec Islands, and on special methods of fertilisation in various genera The wisdom of the choice is seen in the exhaustive and careful compilation now published

The arrangement follows the plan of Hooker's earlier work, and to students of British botany acquainted with Bentham's "British Flora" this manual presents a familiar disposition

Turning to the subject-matter, as the result of the last forty years' work the computation of ferns and flowering plants has risen from about one thousand to nearly sixteen hundred species—exclusive of those naturalised—spread over 382 genera With regard to orders the predominance of Compositæ is natural, but the flora is unusually rich in ferns and species of Scrophulariaceæ, and poor in species of Leguminosæ The number of species in some of the genera is very large, amounting to forty-three in Celmisia, of which all are endemic with one exception, Veronica shows eighty-four species, of which, in contrast to our conception of the genus, seventy-one form shrubs or small trees The flora contains many curious plants and unique associations that have been graphically described by Dr L Cockayne, but from a systematic point of view the most extraordinary fact is found in the enormous proportion of endemic species, amounting to nearly three-quarters of the total

In working through a flora of such vast dimensions and containing so many exclusive species it will be comprehended that Mr Cheeseman has accomplished a task of no small magnitude, and from the critical notes accompanying the technical diagnoses an idea is obtained of the wide knowledge and judicious discrimination that he has brought to bear upon it The author and the New Zealand Government are both to be congratulated on the successful completion of the work

Evidence of incorporation of the latest discoveries is found in the new genus Townsonia and various new species The author has provided in the appendices a

synopsis of orders arranged according to Engler's syllabus, a summary of naturalised plants, and a list of native names

Side-Lights on Astronomy and Kindred Fields of Popular Science Essays and Addresses. By Prof Simon Newcomb Pp vii+350 (London and New York Harper and Brothers, 1906) Price 7s. 6d net

IN bringing up to date and publishing in book form this collection of essays, which have from time to time appeared in various American journals, Prof Newcomb has provided us with a volume which is at once interesting and instructive The range of subjects is a wide one, extending from a discussion of the question, "Can We Make It Rain?" to the flying machine and the structure and extent of the universe

The chapter on the making and using of a telescope should prove interesting to anyone who uses this instrument, whilst "The Fairyland of Geometry" will provide food for thought for many hours to those amateur astronomers whose acquaintance with the science has been restricted to observation only

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications*]

Radium and Geology

IN considering the influence of radium on earth history, it appears to be generally assumed that the radium detected everywhere in the surface materials of the earth is an original constituent of the igneous rocks An entirely different view has been lately pressing itself upon me I put the view forward mainly because I think there are difficulties in the way of accepting the original or primary nature of the radium in rocks These objections I first briefly state

The original nature of the radium cannot be maintained without at the same time assuming the presence of the associated uranium to make good the radio-active decay Now it is easy to show that if such uranium existed grave difficulties arise from the facts of solvent denudation The ocean which receives the dissolved rock materials must be in an entirely different state from what is observed Even assuming geological time as only a very few million years, the quantity of radium now in the ocean should be much greater than has been observed If the river supply of dissolved rock materials had been sustained for only some 20×10^6 years, the sea-salt should possess a richness twenty-five times as great as the ascertained amount

In stating this I make the assumptions—which I think, however are not easily evaded—that radio-active substances are removed from the land along with other mineral matter, and that, along with radium brought into river water on the break-up of rock minerals, the postulated uranium is also carried to the ocean On these assumptions we can arrive at an approximate estimate of what should be the existing state of the ocean on any possible estimate of geological time

We do not require accurate figures We are only really concerned with their order of magnitude I take, in the first place, the Hon R J Strutt's estimate of the radium in sea-salt, stated to be approximate only The quantity is $0\cdot15\times10^{-12}$ grams per gram From this there must be in the ocean about 8×10^9 grams I assume the oceanic mass as $1\cdot468\times10^{24}$ grams On Dr Boltwood's result for the value of λ(year)$^{-1}$ for radium, to maintain this quantity there must in some way be brought into the ocean $1\cdot78\times10^6$ grams of radium per annum

I now turn to the approximate river supply We have Sir John Murray's estimate of the total volume of river water and the dissolved matter therein, which annually enter the ocean. The dissolved matter amounts to $5\cdot1\times10^{15}$ grams. If we suppose the matter in solution still to possess the mean radium content of the igneous rocks as determined by the Hon R. J Strutt, that is, 5×10^{-12} grams per c.c. (and the application of this number can be justified on data at our disposal), we find that 10^4 grams of radium enter the ocean annually from the waste of the land It will be seen, in the first place, that this quantity, unless the uranium enters along with it, is not nearly what is required to maintain the oceanic radium at its approximate present value, but if, on the other hand, the associated uranium enters along with the radium, in 8×10^5 years there would be such an accumulation of uranium in the ocean as to account for the existing amount of radium. But we have not to deal with 800,000 years. If geological time was but a few million years, and solvent denudation had progressed as here assumed, the facts as regards oceanic radium would be entirely different from the observed facts, even allowing a wide margin of error in all the data involved In 100×10^6 years there should be $0\cdot19\times10^{-12}$ grams of radium per gram of sea-salt. I neglect the rate of decay of uranium, as this rate involves periods of the order of thousands of millions of years.

Is there any way of evading this difficulty? If we assume the uranium to be in some way caught in the sediments, and so brought again into dry land, we must expect to find a concentration to occur in them; but the facts are the other way The average radium content of the sediments appears to be less than half (2×10^{-12}) that of the parent igneous rocks, and is, in the case of the detrital sediments and on the assumption of the original nature of the radium, presumably what remains behind with the less soluble constituents of the parent rocks Nor can we suppose the uranium retained in the soils, for then we must face a still more extraordinary concentration of radium, whereas the soils are apparently poor in radium If it is supposed to be concentrated in the rocks beneath the soils, difficulties have to be faced with other heavy metals And in this case, of course, examination of the surface rocks tells us little as to the radium-content of the deeper lying rocks, save that these should contain much less We are observing, in fact, the concentration products of about a mile and a half deep of parent rock removed by the wear and tear of geological time, and know not the depth to which these products extend But such a continued accumulation on the land is hard to comprehend It appears to me that the simplest conclusion is that there is no associated uranium generally distributed throughout the surface materials of the earth I of course do not refer to the ore bodies, thermal springs, &c Again, in certain igneous masses uranium undoubtedly exists occluded in the minerals, whatever history we may ascribe to it

But if there is no associated uranium, whence comes the radium everywhere distributed over the surface of the earth? It cannot be from volcanic sources These are entirely too local in their influence Nor yet can we suppose it to reach the surface, as ores in general do, by means of fissure veins, &c These, again, are quite local in their influence Indeed, the Hon R J. Strutt points to examples of this in the case of the uranium deposits, the adjacent igneous rocks were not abnormal in their radium content

By a process of exclusion, if for no other reason, we are, I think, justified in considering the possibility that the radium is picked up by the earth in its motion through space The probable source would be the sun There are, in point of fact, many arguments in support of this view besides that by exclusion The fairly uniform distribution over the earth's surface at once finds explanation, The picked-up radium probably floats in the atmosphere for a long time, and ultimately is helped downwards to the surface by rain and snow, and other meteorological conditions Once upon the surface of the land, percolating waters will carry it to all depths to which such waters penetrate, It has many thousands of years for its travels

before its radio-activity dies out We would expect that the more impervious mineral substances would show the least amount. Quartz is without radium, as the Hon. R. J. Strutt shows by his determinations

There appears to be no improbability that matter in minute quantities might reach us from the sun Here we are observing the most minute traces If the observations are correct as to the velocities of solar ejections, it would take but a few days to bring solar matter into the orbit of the earth The sun-spot-weather connection may possibly be involved, as well as the phenomena of atmospheric radio-activity, although doubtless emanation from radium already accumulated on the surface and in the soils is mainly responsible for these latter effects Whatever may be said as to the value of such subsidiary evidence, it appears as if only by looking to such an extra-terrestrial origin of radium can we evade the difficulties connected with the associated uranium We are evidently not compelled to assume that the radium received upon the earth carries with it the equilibrium amount of uranium, although doubtless we may expect that some uranium is also received.

It is possible to arrive at a rough estimate of the amount of radium reaching the earth if we assume the annual oceanic supply of radium is mainly extra-terrestrial, and that a state of radio-active equilibrium with the average rate of supply has been attained In effecting this estimate we deduct the annual river supply from the supply required for maintenance of the radium concentration of the ocean The result is an annual supply to the ocean of 1.77×10^{4} grams If this supply is received uniformly over the oceanic area, about 12.5 milligrams enter over each square mile per annum This result is probably excessive, as it assumes no uranium to be in the ocean or received from extra-terrestrial source

If it is permissible to apply to the land area the mean figure deduced for the ocean, we can ascertain the depth to which the observed radium content of the sedimentary rocks would be maintained at its present value It is but trifling—about ten metres As I have indicated above, however, the received radium will be washed from the surface soils and carried into the denser and more retentive rocks The due proportion is doubtless carried to the sea on the break-up of the rocks or by percolating waters We are no longer in difficulties on this score J JOLY

Trinity College, Dublin, January 6

P S—A small quantity of radium will almost certainly be carried to the land along with wind-borne sea-salts * From Pierre's measurements of the latter on a coastal rainfall of 60 cm, I find that about three thousandths of a milligram per square mile (1.2×10^{-15} grams per sq cm) per annum will in this way reach coastal countries This small quantity will not complicate the problem unless there is associated uranium, and unless, further, this latter substance accumulates in the rocks In this case the rocks of coastal countries might in course of time come to have a higher content of radium than interior continental rocks But, I repeat, the supposition that uranium will continually gather in the rocks and never follow the usual channels of escape seems very improbable

Much remains for investigation, naturally arising out of Mr Strutt's fertile work Rain-water should be systematically examined, due allowance being made for wind-borne radium carried from the sea. I have begun such observations, but they will necessarily demand time and care if they are to be of value In the hope of getting further light on some of the points at issue, I have the rocks of the Simplon Tunnel and certain of the deep-sea oozes under examination J JOLY.

January 16

Green Sunset Colours.

THE green sky described by Mr Collins in NATURE of January 3 (p 224) was evidently an unusually brilliant example of the green tints often seen in a sunset sky As I have not seen any explanation of the phenomenon, it may possibly be of some interest to give the following attempt at one

The colour of the sky at any time is made up of two components A, the light from the upper regions, B, that reflected from the small particles in the lower air The A component is always blue, and its spectrum shows a deficiency in red and yellow rays Its light passes between the particles, and therefore forms a background upon which they are projected The spectrum of the B component is variable When the sun is well above the horizon the light is white, and the variations in the deepness of the blue of a clear sky are due to differences in the relative proportions of A and B As the sun nears the horizon the B light begins to lose its more refrangible rays, and the absorption extends towards the green and yellow as the sun goes down

Now if we take two equally brilliant spectra, cut out the red, orange, and yellow from one, and the violet and blue from the other, and then mix the residues, we shall obviously have all the colours necessary to make white light with a double allowance of green An eye receiving the whole will see pale green This, I take it, is the origin of the green colours of the sky The A component is deficient in the less refrangible rays, which are supplied by the B component, and the two spectra overlap in the green, showing an excess of that colour

Occasionally, but rarely, the two are exactly complementary over a limited stretch of sky, and then white patches are seen amid the colours of the sunset which are easily distinguished from clouds They shade off on one side into tints of green where the spectra overlap, into yellow where the B component is in excess, and into blue where the A light preponderates

When the sky is clear it is no uncommon thing to see a considerable expanse of green, shading on the one side into pale lemon-yellow where the overlap of the spectra is considerable, while on the other side it shades through a narrow border of silvery tint where the balance is exact into a delicate rosy hue where there is a general deficiency in the central rays

Green tints are by no means always to be seen and I think the foregoing explanation shows why—their production depends upon such an adjustment between the brightness of the two components that they shall be approximately equal The white patches are rarer still, as they require exact equality in brightness and correct apportionment of colour ARTHUR W CLAYDEN

5 The Crescent, Exeter

Ultra violet Fluorescence of Benzene

FROM my observations on the emission of light by canal rays (*Ann d Phys*, 21, 401, 1906, *Physik Zeitschr*, 7, 355, 1906), I have concluded that absorption of light in a band spectrum (running towards the red) produces fluorescence Hartley and others have stated that benzene has a banded absorption spectrum in the ultra-violet, adopting that principle, I conjectured that benzene had an ultra-violet fluorescence I have confirmed this by the following method —The ultra-violet rays from a mercury lamp by W C Heraeus (Hanau, Germany) fell vertically upon a diluted solution (0.25 per cent) of benzene in alcohol, and the fluorescence light emitted by it horizontally was analysed by a quartz spectrograph In the spectrograms obtained there appeared, besides the mercury lines, a group of four strong continuous bands situated in the ultra-violet between $\lambda\lambda$ 271 and 314 $\mu\mu$, these bands run towards the red end of the spectrum, and the heads have the wave-lengths 272, 280, 283, 292 $\mu\mu$

As Hartley has shown, the absorption spectra of the benzene derivatives are produced by an alteration (both in intensity and spectral position) of the simple benzene spectrum, such an alteration is produced by condensation and substitution According to our principle, the same is true for the fluorescence spectra of the benzene derivatives. The question as to the relations between chemical constitution and fluorescence is thus reduced to the question of the relations between chemical constitution and absorption, and banded absorption must be explained with regard to the fact that it is coupled with fluorescence There may also be drawn from the above result some conclusions about the constitution of the benzene ring

J STARK

THE KINGSTON EARTHQUAKE

WHEN Port Royal was destroyed by the great earthquake of 1692, some of the surviving inhabitants took refuge on ships, others moved across the haven to a place called Kingstown or Killscown, where, in huts made of boughs, exposed to the heavy rains and in close proximity to hundreds of dead bodies in the bay, they "died miserably in heaps." Port Royal was rebuilt and maintained as a naval station; its successor, as a place of business, was founded the following year at Kingston, and by the earthquake of January 18 has now met with a similar, though fortunately less complete, destruction.

The two earthquakes differed considerably in intensity. In 1692 the whole island suffered. Scarcely a house in any part of it was left standing. By numerous land-slips, the mountains were stripped of vegetation and altered in form. The earthquake of that year was one of the first order of magnitude. The most remarkable fact about the recent shock is the very limited area of damage. Kingston seems to have suffered most severely. The more important buildings are ruined, and few, if any, houses have escaped some injury. Port Royal, six miles to the south, and St. Andrew, within five miles to the north, have shared to a great extent in the ruin, but outside a radius of ten or twelve miles from Kingston the loss to property is small. Some houses in Spanish Town, eleven miles to the west, are said to be damaged, while Port Antonio twenty-eight miles to the north-east, and Holland Bay, thirty-eight miles to the east, are almost unharmed.

From the small area of excessive damage and from the rapid decline in the intensity of the shock, it may be inferred that the focus was situated close to Kingston and at no great depth below the surface. Partly to the proximity of the focus, partly also to the sandy or gravelly nature of the ground (for earthquakes are always more strongly felt on loose, friable beds than on hard, compact rock), we must attribute the destructive energy of the shock. That, in its initial power, the earthquake was inferior to those of Valparaiso and San Francisco is clear from the smallness of the meizoseismal area, and also from the comparatively slight disturbances recorded at the observatories of Washington, Shide, and Edinburgh.

The onset of the shock was sudden, there being no warning tremors or sound. For thirty-six seconds the motion was like that felt on a ship in a choppy sea. All observers agree that the movement was chiefly vertical. It is said that objects jumped from the ground, and this, if it be true, shows how violent was the shock and how close was Kingston to the focus. In many places the ground is fissured, the electric-tram rails are twisted, and the water supply pipes are partially damaged—all indications of a neighbouring focus. The direct line of cable to Colon is broken about three miles from the shore, pointing either to a displacement of the ocean-bed or to a submarine land-slide—probably to the latter, for there were no marked seismic sea-waves on the south side of the island,[1] and the shipping in the roadstead and harbour are unharmed. The subsidence of the battery at Port Royal and the sinking of the shore at Kingston show that the superficial beds, at any rate, have undergone important changes of level.

Whether these changes be due to bodily displacements of the crust, to mere shifting of the surface-beds or to both is by no means clear. When the island was surrendered to English forces in 1655, the spit, called the Palisadoes, which now terminates in Port Royal, was discontinuous, and the end resembled one of the quays or small islands outside the harbour. By 1692 the gap was bridged by a bar of sand. During the earthquake of that year a portion of the spit, a quarter of a mile in length, suddenly subsided, so that only the chimneys or upper parts of houses that were not overthrown appeared above the water. The harbour of Port Royal also sank, so that the streets along the harbour-side afterwards lay at a depth of from four to eight fathoms. Yet the depression of the ground itself at Port Royal and in other places was not supposed to exceed a foot.

There can be no doubt from the evidence above described that the seismic focus was situated, in part at least, almost vertically below the haven between Kingston and Port Royal, though a portion of it may have extended as far as three miles to the south of the coast. It is also probable that the Port Royal and Kingston earthquakes originated roughly within the same focus.

The West Indian region is distinguished by those steep surface-gradients which characterise areas of great instability. Jamaica, in common with Porto Rico and the south of Haiti, lies along a crust-ridge, which towards the west is prolonged into the mountains of Honduras, while it is separated from a corresponding ridge constituting the island of Cuba, by the submarine depression of the Bartlett deeps. To the east, the Jamaican and Cuban arcs unite in one main ridge which bends round to overlap the curved line followed by the volcanic islands of the Lesser Antilles. These form the north and east boundaries of the great deeps of the Caribbean Sea. On the south lie the mountain ranges of Venezuela, &c., which, as we know from the destructive earthquakes of Cumana in 1799 and 1853 and of Caracas in 1812, are still in the stage of vigorous growth. Towards the west, and connected with the West Indian series, are the central American chains, also studded with volcanoes, and in parts frequently visited by violent earthquakes. In this West Indian region as elsewhere, it is not unlikely that the mountain arcs have a tendency to press forward on their outer and convex side, and to subside towards the interior of the arcs. The movements along the line of the Lesser Antilles certainly suggest a slipping westwards into the Caribbean deeps. In Jamaica, along the northern boundary of that sea, the movement may be more complex, the northern side of the Jamaican ridge having a tendency to move northwards and forwards towards the Bartlett deeps, while on the south there is a continued subsidence and slipping towards the Caribbean Sea. Of such intermittent slips, the Port Royal and Kingston earthquakes appear to be some of the latest manifestations.

So far as I am aware, there is no evidence of that intense crushing that was so conspicuous a feature of, say, the Japanese earthquake of 1891. Extension rather than compression was manifested in 1692, for at Port Royal one whole street, in which many houses were left standing, was said to have been doubled in width by the earthquake. There is much evidence to favour such a view in the case of the Kingston earthquake—the extremely local character of the destructive shock, the snapping of the cable to the south, and the minor character of the disturbances registered by distant seismographs.

CHARLES DAVISON.

[1] A so-called "tidal" wave was observed on the north side of the island. It is said that Anotta Bay was inundated and that houses were swept away. No time is mentioned, and if the sea waves were of seismic origin, we should expect to hear of similar reports from Port Antonio and other adjoining harbours.

A PICTURESQUE HISTORY OF DACCA[1]

THIS very interesting and picturesque historical story portrays the dwellers in the land where the two great waterways of eastern India, the Brahmaputra and Ganges, unite before they fall into the Bay of Bengal It tells how they and their forefathers have by their persevering industry, ingenuity, and commercial ability made Dacca and its adjoining predecessors, Rampal and Sonargaon, capitals of a kingdom which, though often disorganised by misgovernment and robbed by its neighbours, the Mughs and Assamese, yet always when allowed to manage its own affairs in peace rose again to be a busy and prosperous manufacturing city

The early history of these successive towns is traceable in the annual popular religious festivals of the country The two chief of these are, first, the Jamastami, held on the 23rd of the lunar month Srabon (July–August), as the birthday of Krishna, tutelary god of the weavers of the incomparably fine muslins which had enriched the merchants of Dacca and its predecessors when weaving was the chief industry, and, secondly, the Nangulbundhi plough (nangul) making festival of Cheit 8 (March–April), of which an illustration is here reproduced Both are admirably described in this book, but it is the last which creates the greatest and most universal popular enthusiasm, as being the birthday of the land and of the plough which tilled the fields of cotton whence the Dacca muslin was woven

The plough-god of the feast is Parasu-Rāma of the two-bladed axe (parasu), whose first birth story was framed in western India by the fire-worshippers who made the household and altar fire their national god In the Mahābhārata he is the great-grandson of Bhrigu, the father of fire, whose son Richika, the fire-spark (richi), begot from the two sacred mother fig-trees the Banyan and Pipal, whence the altar fire was engendered, Jama-d-agni, the twin (jama) fires (agni) His wife was Renuka, the flower-pollen (renu), and their fifth son was Parasu-Rāma He slew his mother with his two-bladed axe, the two lunar crescents of the waxing and waning moon, and this story tells us in symbolical language that he was born as the generating seed to be ploughed into the earth when his flower-mother died In his history, as told in this book (pp 295–8), he fled to the source of the Brahmaputra to obtain pardon of the sin of matricide, and there God changed his axe to a ploughshare, which cleft the mountain and made a way to the sea for the holy river In his western Indian legend he is said to have made the sons of the fig-tree rulers of India by conquering and slaying its Haiheya masters, who survive in eastern India as the Mughs, who gave their name to Maghada, now Behar They were the first settlers in the Gangetic valley, and in the history of Dacca always attacked and robbed its people when they were unable to protect themselves, and their successors, Parasu-Rāma's sons, ploughed the cotton fields which fed the looms of the Dacca weavers Like the Kurmis who first grew cotton in the black soil of western India, they covered the country with water-tanks like those made by the road- and lake-making Sen king Ballal Sen, whose capital, Rampal, took its name from the plough-father Rāma, whose sons peopled the Indian river valleys before the later traders, whose god was Krishna

[1] "The Romance of an Eastern Capital By F B Bradley Birt Pp. x+349. (London Smith, Elder and Co, 1906) Price 12s 6d net

The early history of the union of the farming, pastoral, and artisan founders of the Indian nation is told in the Gond poem the Song of Lingal, the Linga god It says that Lingal united them as subjects of the Tortoise (Kush), which in the primitive national geography supports the earth floating on the ocean The races thus united were the Nāga-Kushikas, who with their successors, the Ikshvāku, sons of the sugar cane (iksha), laid the foundations of Indian society The Nāgas were the Haiheyas, whose empire, when they were conquered by the Mahrattas in 1740 A D, had shrunk to the Nāga countries of Nagpur and Chutia Nagpur in Central India The Kushika were the sons of the Kusha grass sacred to Krishna, the black antelope god and it was with it that in their ritual his national earth altars on which milk libations were poured were thatched, and their Prastara the magic rain-compelling wand borne by the high priest, was made of Kusha grass These altars were by the Ikshvākus, who offered animal sacrifices, thatched with the boughs of a new sacred fig tree, the Plaksha or Pakur (*Ficus infectoria*), and their Prastara was made of Ashvavala (*Saccharum spontaneum*), wild sugar-cane grass The Kushika marriage rite, which united each wedded pair by binding their hands together with Kusha grass, still survives among the Chasas and Koch Rajbunsis, the chief cultivators of Orissa and eastern Bengal, and many other trading castes

Pilgrims bathing in the Sacred River during the Nangul bundhi Festival From 'The Romance of an Eastern Capital

The artisan and trading offspring of these pioneer races ruled Rampal when its kings were, at the close of the age when Buddhism was the prevailing religion of India, the Pals They belonged to the Subarna Banik clan, of which many of the richest merchants and bankers of Dacca are members and which claims descent from the Naga Rishi and

Kashyapa, the Kushika father. Also their successors, the Sen kings, who restored the Hindu ritual and made Sonargaon their capital, are shown by their name to belong to the Subarna Bhanik clan.

The later kings of this dynasty became tributary to the first Mohammedan conquerors under Bukhtiyar Khilji, and were finally dethroned by Tughral Khan and Balin, Emperor of Delhi, and his successor, Alla-uddin, made Sonargaon and its territories the eastern province of Bengal. Its subsequent history tells of the rule of successive viceroys, their rebellions and wars with the Delhi emperor, ending with the conquest of Bengal by the Afghan king Sher Shah and his clan, of whom the last ruler was Isha Khan, the converted Hindu. His marriage with the Hindu Sona Bibi, his successor, and his submission to Man Singh, Akbar's general, whom he had worsted in single combat, furnishes one of the most stirring tales here told. The story then tells of the building of Dacca by Jehangir's viceroy, Islam Khan, in 1608 A.D., and of the generally troublous rule of the viceroys of the Emperors Jehangir, Shah Jehan and Aurungzebe, in whose reign Dacca enjoyed twenty-five years of exceptional prosperity under Shaista Khan, Shah Jehan's first cousin, and uncle by marriage to Aurungzebe, who married Shaista Khan's niece. Under his rule the English came to Dacca, and the story of their early struggles and final conquest of Bengal is most ably told in this book. The introduction of English machine-made cloth and English thread ruined the muslin trade of Dacca, and made it first an indigo mart and afterwards what it now is, the centre of the Bengal jute trade.

J. F. HEWITT.

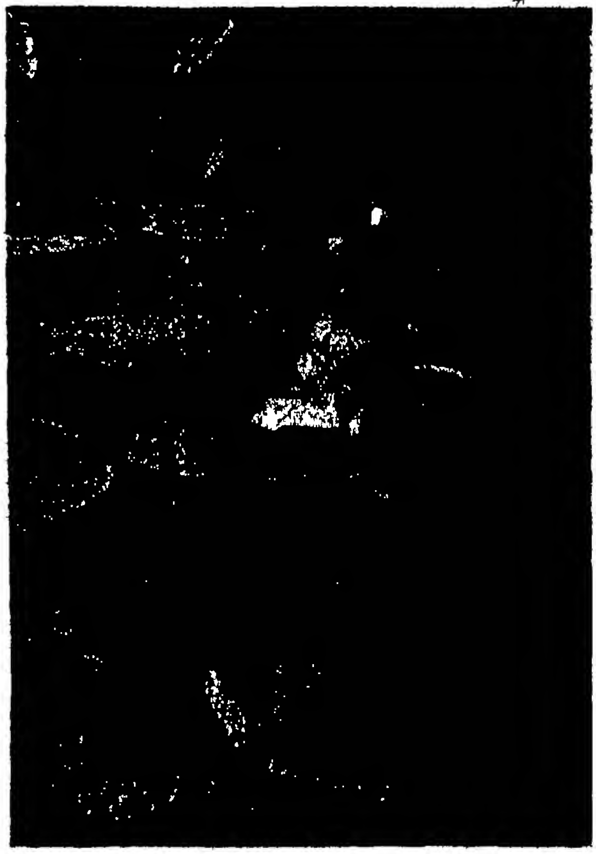
PLANT LIFE.[1]

UNDER the somewhat indefinite title "How Ferns Grow," the author refers mainly to the changes that occur in the succession of leaves from the cotyledon of the sporeling to the mature leaf of the sporophyte. It is suggested that in addition to the possibility of tracing phylogeny by means of ontogeny, a knowledge of the successive stages is likely to be of importance in the determination of species and varieties. These ideas are not, however, followed up, nor does the author offer the deductions that would be expected after the examination of a large number of series of young plants. From the illustrations it appears that a reniform shape characterises the earliest leaves of *Pellaea atropurpurea*, and the juvenile leaves of *Onoclea sensibilis* are somewhat similar; also the early leaves of the hart's-tongue and the walking fern, *Camptosorus rhizophyllus*, show similarity. But the figures given and the number of species examined are too few to permit of much, if any, generalisation.

Books on plant life are becoming numerous, too numerous, and yet books on the subject suited to the special requirements of different schools are not obtainable. Of the various books written for children in elementary schools, the "Study of Plant Life," by Miss Stopes, is quite the most logical and intelligent that we have seen.

Beginning with the physiology of the plant, the first object is to show that a plant lives, that it breathes, eats, grows, and moves. These functions are severally made apparent by simple experiments that can for the most part be carried out by children, and are explained with due care to impress their significance. The parts of the plant body and their uses are then discussed, and this prepares the way for the descriptions of their more marked and common modifications. The fourth part briefly enumerates the characters of the five great classes of plants. Passing to the consideration of plants in their homes, typical plant formations are described, and finally it is indicated how a botanical survey is made and plotted.

The foundation of the book is laid in the first part, treating of the plant's vitality, where the argument is well set out. The only suggestions that occur are of a minor nature, such as recommending other plants,



Victoria Regia in a public park in Minnesota. Reduced from an illustration in "The Romance of Plant Life."

the fuchsia or *Eupatorium adenophorum*, rather than the vine for root pressure, directing attention to the necessity of setting up a large number of culture solutions, &c. Throughout the book it will be found that the information is essentially clear and practical, the specimens selected for study easily obtainable, and the arrangement well balanced. While the figures generally are good, the plates illustrating water-plants and bladder-wrack are specially clever reproductions, altogether the book provides an admirable presentment of botanical instruction for children.

"Plant Life," by Mr. H. C. Jones, in contrast with the last, provides a series of notes on suitable work for nature-study classes.

It is divided into two portions, the first referring to plant life in the garden, the second to plant life in the school. The former includes chapters on twigs, bulb beds, insect fertilisation, underground stems and roots,

"Plant Life: Studies in Garden and School." By H. F. Jones. Pp. xii+260. (London: Methuen and Co., n.d.) Price 3s. 6d.

"The Romance of Plant Life." By G. F. Scott Elliot. Pp. 380. (London: Seeley and Co., 1907.) Price 5s.

"The Green Gateway: a Peep into the Plant World." By F. G. Heath. Pp. xi+138. (London: The Country Press, n.d.) Price 3s. net.

creeping plants, and other modifications Strange to say, modifications of flower form are omitted except in the occasional notes The second is a physiological course dealing with the energies of the plant This is more systematic in arrangement, and the experiments are tersely explained, but no new ideas or special hints are offered The methods suggested for setting up some of the experiments are by no means the most practical, to mention only the growing of a seedling in a funnel, or extracting chlorophyll by boiling the leaf in alcohol over a Bunsen flame As an indication of observational and experimental work that can be performed with simple apparatus, the book will be found serviceable, and the appendix contains a useful list of plants for growing

Mr Scott-Elliot brings to his subject an extensive knowledge of the ways of plants, and the instinct of imagination that enables him to appreciate the romance connected with the facts he has collected He relates, however, no tales so fascinating as the accounts one has read of the adventures of collectors in quest of orchids or other rare plants, nor is any attempt made to depict that most attractive of all phases of plant life, the tropical forest The author has selected most of his scenes from non-tropical regions, except where he writes of mangrove swamps and deserts The various relationships between animals and plants, specialisations of flowers, fruit and seed, and of the plant generally are among the subjects treated and economic botany receives a due share of recognition There is no want of variety in the book, in fact, the fragmentary nature of the subject-matter constitutes its chief defect, and much of the information whets the appetite for more The author has, we think, produced his best results where, as in the sketch contrasting ancient and modern Britain, he pursues a continuous topic

As a compilation of curious facts about plants, spiced with occasional grains of humour and light caustic satire, the reader will find much of passing interest and not a little that is worthy of closer attention The best illustrations represent economic scenes, but a more romantic subject is shown in the picture reproduced on the preceding page

There are various ways of appealing to the youthful mind, that adopted by the author of "The Green Gateway" being to arouse interest by copious allusions to magic, fairy work, and jewels Although fairy tales may be useful to stimulate the imagination, it is doubtful whether they form a suitable medium in which to portray science A tree and its parts form the central subject of the book, but it is probable that children will be most interested in the tales of the animal inhabitants and visitors of the tree, that are attractively described without reference to fairies and magic

PROF A F W PAULSEN

It is with great regret that we chronicle the death of Prof Adam F W Paulsen, which occurred in Copenhagen on January 11 Born in 1833 at Nyborg, in the island of Funen, Paulsen studied at the University of Copenhagen, in which town he subsequently held the position of professor of physics at the Lycée In 1884 he was appointed director of the Danish Meteorological Institute, one of the most important official meteorological positions, in view of the fact that the Danish Institute is responsible for the meteorological organisations of Greenland and Iceland, He was also a member of the Permanent International Meteorological Committee

Among Prof Paulsen's most important scientific labours must be reckoned his researches on the aurora borealis His attention was first actively directed towards this phenomenon during his stay at Gothaab in 1882–3 as head of a scientific expedition sent out by the Danish Government The question of the aurora remained one of absorbing interest to Paulsen, and in 1899–1900 he obtained from the Government the means for equipping an expedition to visit Iceland for the purpose of studying the spectrum of the aurora with the aid of modern photographic methods At the comparatively advanced age of sixty-six years he assumed personal command of the expedition, and brought back with him some highly interesting results He read a brief account of these before the British Association at the Southport meeting in 1903, which he attended as a member of the Permanent International Meteorological Committee

As director of the Danish Meteorological Institute, Prof Paulsen was the head of that meteorological organisation of which the area of observation lies nearest to the North Pole He never ceased to point out the intimate connection which exists between the meteorological conditions of Greenland and Iceland and those prevailing over Europe, and it is largely owing to his efforts that after many years of discussion and negotiation Iceland has at length been brought into telegraphic communication with Europe The daily service of meteorological messages which was established shortly before his death is likely to prove of great value both in the practical matter of forecasting and in the study from the scientific point of view of the permanent Icelandic low-pressure system and its influence on the weather of north-western Europe

Prof Paulsen was a familiar figure at international scientific meetings where his charm of manner, combined with great accuracy of judgment and a clear mode of expression, rendered him deservedly popular His last visit to this country occurred in the summer of 1904, when he attended the meeting of the International Association of Academies as delegate of the Royal Danish Society of Sciences

NOTES

At the annual meeting of the British Science Guild to be held at 4 p m on Monday next January 28, at the Mansion House under the presidency of the Lord Mayor, the Right Hon R B Haldane will deliver an address in relation to the work of the Guild Other speakers will probably be the Hon and Rev F Lyttelton, Sir David Gill, Sir Wm Mather Sir Henry Roscoe Sir Philip Magnus, M P Prof Meldola Mr A Haworth M P, Mr Mosely, and Mr Verney

We regret to see the announcement that Miss Agnes M Clerke, the gifted author of several well known works on astronomical subjects, died on January 20 at the age of sixty-four years The first important work on astronomy written by Miss Clerke was the "Popular History of Astronomy during the Nineteenth Century," published in 1885 Other works of outstanding merit are "The System of the Stars" (1890) and "Problems in Astrophysics" (1903) Her command of language and acquaintance with astronomical literature were extraordinary and empowered her to produce books distinguished by literary finish as well as by scientific value Miss Clerke was a most industrious compiler of methods and results of astronomical investigation The "History of Astronomy" was her most valuable contribution to scientific literature and her later works, though marked by the same inspiring style dealt with the more special aspects of astrophysics In

reading these works, it is impossible not to feel regret that an enthusiasm so great should have lacked the advantage of a laboratory training, which would have enabled Miss Clerke to estimate the real value of the various researches successfully recorded "No one writing a history of modern astronomy," says a correspondent of the *Times*, "can fail to acknowledge the great debt owed to the masterly array of facts in her 'History' No worker in the vast field of modern sidereal astronomy opened by the genius of Herschel and greatly widened by the application of the spectroscope to the chemical and physical problems of the universe lacked due recognition by Miss Clerke, who performed as it seemed no other writer could have done the work of collation and interpretation of this enormous mass of new material, ever pointing the way to new fields of investigation, often by one pregnant suggestion sweeping aside a whole sheaf of tentative conjectures and indicating, if not the true line—for in many cases the truth is yet to seek—at least a plausible and scientific line well worth pursuing"

THE Rothamsted Experimental Station (Lawes Agricultural Trust) has received a donation of 2000*l* from the Permanent Nitrate Committee, to be invested and added to the general endowment fund of the station A donation of one hundred guineas has also been received from the Fertiliser Manufacturers' Association During the past summer the station entered into occupation of the "James Mason" Bacteriological Laboratory, the gift of Mr J F Mason M P The society for extending the Rothamsted experiments, which was formed to obtain funds wherewith the experimental station might enlarge the scope of its work and initiate further agricultural investigations, has further received during the past year subscriptions and donations amounting to 240*l* Further subscriptions are still urgently needed to secure a more adequate staff, and may be addressed to the Secretary of the Rothamsted Experimental Station Harpenden, Hertfordshire

A REUTER message from The Hague, dated January 22, reports that a wave has destroyed the southern coast of the island of Simalu, near Sumatra The island of Simalu has nearly disappeared Violent earthquake shocks have occurred daily

A REUTER telegram from Vyernyi (Turkestan) states that the eclipse of the sun on January 14 was not observed there owing to cloudy and foggy weather

THE second National Poultry Conference will be held on July 9-11 at University College, Reading The honorary secretary of the conference is Mr Edward Brown, 12 Hanover Square, W

DR H R MILL has been elected president of the Royal Meteorological Society for the ensuing year, and Mr F C Bayard and Mr H Mellish secretaries of the society At the annual general meeting of the society on January 16 Mr Richard Bentley, the president, on behalf of the members of the council, presented an illuminated address to Mr William Marriott in recognition of his services as lecturer

THE annual general meeting of the Iron and Steel Institute will be held on Thursday and Friday, May 9 and 10 The annual dinner will be held—under the presidency of Sir Hugh Bell, Bart—in the Grand Hall of the Hotel Cecil on May 10 The council will shortly proceed to award Carnegie research scholarships, and candidates must apply before February 28. The awards will be announced at the general meeting

THE Explosives in Coal Mines Order of December 17, 1906, has been issued by the Home Office in the form of a pamphlet of sixty-six pages (price 4½d) It contains full details of the composition of the fifty-eight explosives the use of which is permitted in unsafe collieries if certain specified conditions be observed

THE pipe line conveying petroleum from Baku to the Black Sea has been completed It is 550 miles long, and is capable of passing 400,000,000 gallons of oil yearly. Another important oil-pipe line has been built for transporting Texas and California petroleum across the Isthmus of Panama It is 8 inches in diameter and fifty-one miles long

ON Tuesday next, January 29, Prof A C Seward will commence a course of two lectures at the Royal Institution on "Survivals from the Past in the Plant World," and on Thursday January 31, Major P A MacMahon will deliver the first of two lectures on "Standards of Weights and Measures" The Friday evening discourse on February 1 will be delivered by Sir Almroth E Wright, on "The Methods of Combating the Bacteria of Disease in the Interior of the Organism"

THE thirty-eighth general meeting of the German Anthropological Society will be held in Cologne in August next It is proposed that this meeting should be constituted an international congress, and the Cologne Anthropological Society has issued a cordial invitation to fellows of the Anthropological Institute and others interested in anthropology and archæology to attend the congress It is further proposed to arrange a tour of two or three weeks in the Low Countries and France to take place after the congress During this tour places of the greatest interest from an anthropological point of view will be visited In case a section of the visitors would prefer to make a tour in Germany, the authorities state that they will consider the possibility of carrying out any proposition they may receive A complete programme will be published very shortly Meanwhile, fellows of the institute and other students of anthropology and archæology who would like to attend this congress are requested to communicate with the secretary of the Anthropological Institute, 3 Hanover Square, W

THE Faraday Society, the object of which is to promote the study of electrochemistry, both pure and applied, and also the study of chemical physics, is endeavouring to develop this latter side in the hope that the physical-chemical work done in this country may be published in its Transactions instead of being published in various Journals, and much of it abroad With this object in view the society held a meeting on January 15 to discuss the electron theory as applied to conduction in electrolytes, and on Tuesday, January 29, there will be a meeting at which a general discussion on osmotic pressure will take place Prof Armstrong will be in the chair, and the Earl of Berkeley will exhibit and describe his apparatus for the direct measurement of osmotic pressure Mr W. C D Whetham will speak on indirect methods of measuring osmotic pressure, Dr T M Lowry on osmotic pressure from the standpoint of the kinetic theory, and a paper by Prof Kahlenberg is expected upon the bearing of osmotic-pressure experiments upon the conception of the nature of solutions The society invites all who are interested in the subject to be present The meeting will be held, as

usual, in the library of the Electrical Engineers, 92 Victoria Street, S.W.

A RECEPTION and exhibition of recent progress in science was held by the New York Academy of Sciences in conjunction with the American Museum of Natural History on December 28 and 29, 1906, and, for the benefit of the public, the exhibition was continued daily until January 14. The 353 exhibits were arranged in eighteen sections, covering nearly every department of natural knowledge, and the exhibition as a whole was a tribute to the organising powers of the managing committee. The New York Academy of Sciences is one of the oldest among American societies, having been established in 1817 as the Lyceum of Natural History. It embraces all branches of science; its scope, in fact, is similar to that of the older European societies. Its publications have long been familiar to readers of NATURE. Its membership includes a maximum of fifty honorary members elected from representative men of science throughout the world, more than 200 corresponding members, who are expected to communicate the results of their researches to the academy from time to time, and the active and associate members. Active membership is not restricted to specialists, but is open to those who take a general interest in science. Fellows are chosen from among the active members in recognition of scientific attainments or services.

A DEPUTATION representing the Infants' Health Society waited upon Mr. John Burns, M.P., President of the Local Government Board, on January 17, with reference to the supply of sterilised milk to infants. Several local authorities have recently established depôts for the supply of sterilised milk for infant feeding. The opinion has been expressed that in so doing the authorities have exceeded their legal powers, and Mr. Burns has therefore intended to introduce a Bill to legalise their action. The Infants' Health Society, believing that sterilisation is of doubtful value, and that refrigeration is preferable, asked that before sterilisation was sanctioned an investigation should be made by a committee of experts which it is proposed to form. Sir Thomas Barlow, Sir Lauder Brunton, and Mr. Mayo Robson having detailed the views of the society, Mr. Burns in reply said that he knew that sterilisation was not the last word in dealing with the problem of the milk supply, and at present he saw no reason why a choice should not be given between the two methods of sterilisation and refrigeration, and why he should not embody in his Bill the power being given to local authorities to sterilise milk. With regard to the investigation of the question by a joint committee, he would be glad if such a committee would communicate to him the results of their investigations.

THE valuable collection of British and foreign Algæ made by Mr. E. M. Holmes, of the Pharmaceutical Society, has, through the generosity of Mr. William A. Cadbury, been acquired for the botanical department of the University of Birmingham. The collection is a very large one, including about 13,000 specimens, and constituting the produce of more than thirty years of Mr. Holmes's activity as a collector. The British portion of the collection is of exceptional value, owing to the singularly prolific nature of Mr. Holmes's personal investigations. When he commenced his work thirty-five years ago there were some 400 species of British marine Algæ known. There are now about 750, and 225 of the new species were distributed by Mr. Holmes himself, in eleven fasciculi. Of these, twenty-five sets only were issued, and with three or four exceptions these sets were acquired for national collections or British or foreign universities. As some of the best collecting grounds of the past, such as those near Weymouth, Plymouth, and Falmouth, have been in large measure spoilt by extensions of building areas, the difficulties in the way of making a complete collection are of increasing magnitude, while three or four of the specimens included in the collection are unique. The foreign portion of the collection is as complete as could have been made in the period, and includes authentic sets sent out by all the best known algologists, such as Harvey, Agardh, Bornet, Thuret, Crouan, Ferguson, and others. Here also not a few of the specimens are types, having been used as the basis of published specific descriptions. As Mr. Holmes had long planned that his collection should be fitted for public rather than private ownership, exceptional care has been taken throughout in respect of display and mounting, and different species or different varieties are in no case included upon the same sheet. The donor also states, as a condition of gift, that the collection shall be accessible to algologists generally for any purposes of serious study or of reference.

BRITISH sea fisheries, and more especially those of the North Sea, form the subject of an instructive article in the January number of the *Quarterly Review*. After a survey of the results of earlier investigations the author discusses those of the last three or four years, which are based on much more precise information than was available in the case of the former. Starting with the axiom that a given area of the sea can nourish only a limited amount of fish, it is pointed out that if the methods of capture tell more heavily on one kind than on another it is quite probable that valuable species may be largely displaced by inferior ones. This seems to be the condition of affairs in the North Sea, where the worthless dab is increasing at the expense of the plaice. Possibly the remedy for this is the introduction of young plaice. Subsequently, in discussing the excessive destruction of young fish which undoubtedly takes place, the question is raised whether this has really any marked effect on the adult population; certainly it does not appear to do this in the case of the herring. Be this as it may, it seems clear that the Grimsby supply is largely maintained by drawing on immature fish. Admitting this, it has yet to be proved that the destruction of young plaice is not the consequence rather than the cause of the depletion of the grounds. If this be so, it follows that the undersized-plaice problem must be considered from a fresh standpoint—the expectation that by checking the capture of young fish the sea will be replenished being obviously untenable. Apart from the grave condition of that of the North Sea, the author expresses the opinion that the condition of British fisheries generally was never better than at present. Obviously, however, interference of some kind must eventually be necessary in nearly all cases, and if this be so it is of the utmost importance that our knowledge of the fishery problem in all its aspects should be made as nearly as complete as possible while prosperity lasts. The Government is, therefore, urged to increase rather than slacken its efforts and support.

IN connection with the preceding note it may be mentioned that there has been recently installed in the central hall of the Natural History Museum an exhibit prepared by the Marine Biological Association, Plymouth, to illustrate the growth of plaice and pollack, and the methods of ascertaining the ages of individual specimens of each

In the case of the former, the age estimate is made by counting the annual rings of growth in the ear-bone or otolith, whereas in the latter the scales are employed for the same purpose. Enlarged photographs of these structures in the two species are exhibited.

THE Colonial Office has just issued a report of the advisory committee of the Tropical Diseases Research Fund for 1906. This committee was constituted in July, 1904, and consists of Sir T. Barlow, Sir M. Foster, Sir P. Manson, Sir R. Moor, Surgeon-General Bransfoot, and Messrs. Holderness, Lucas, and Read, with Sir West Ridgeway as chairman. The revenue of the fund for 1906 amounted to 3000*l.*, and was made up of contributions from the Imperial Government, Government of India, Rhodes trustees, and various Colonial Governments. The expenditure consisted of a grant of 500*l.* to the Liverpool School of Tropical Medicine, of 1000*l.* to the London School, of 750*l.* to the University of London, and of 500*l.* to the Royal Society. The report includes summaries of work done during 1906. Mr. Leiper, the helminthologist of the London School, has investigated the life-history of the *Dracunculus medinensis*, or guinea-worm, the cause of a disease widely disseminated in tropical Africa. The embryo, after leaving the human body, develops into larvæ, which enter the body of a small fresh-water crustacean of the genus Cyclops. The larvæ do not spontaneously leave the Cyclops, but if the crustacean be treated with 0.2 per cent. hydrochloric acid it dies and the larvæ are awakened into activity and escape. This suggests that man is infected by swallowing water containing infected Cyclops, and by feeding monkeys with infected Cyclops guinea-worm infection was produced. Dr. Wenyon describes a new species of spirochæte of the mouse, and summaries of investigations on the value of arsenical preparations in sleeping sickness and on other subjects are also given.

No. 9 of the *Kew Bulletin*, completing the volume for the past year, contains a list of marine algæ from Corea, by Mr. A. D. Cotton, and a decade of new orchids named by Mr. W. L. Rolfe. Mr. W. B. Hemsley communicates a note on a new fruit from Uruguay, about the size and shape of a very small apple, having an agreeable taste and said to possess remarkable digestive properties. The plant belongs to the Sapotaceæ, and receives the name of *Pouteria suavis*. Short notices of the dye substance known as barwood, now referred to *Pterocarpus Soyauxii*, and varieties of the Chinese drug, "huan-ch'i," furnished by species of Astragalus, are contributed by Mr. J. M. Hillier and Mr. E. H. Wilson.

A PAPER on the planting of high moorlands appears in the Transactions of the Royal Scottish Arboricultural Society, vol. xx., part i., wherein the writer, Sir John Stirling Maxwell, advocates a Belgian system of utilising the turfs cut out from the drains as mounds in which to plant out seedlings. A variety of *Pinus montana*, grown largely in the Pyrenees, is mentioned as a tree that is likely to grow well on high moorland. Dr. R. S. MacDougall contributes an entomological article on the life-history of the large larch sawfly, *Nematus erichsoni*, and Mr. E. S. Grant describes a method of trapping the pine weevil *Hylobius abietis*. A useful set of measurements indicating the increase during fourteen years of a larch crop growing at Murthly, Perthshire, is given by Mr. A. Murray, and a table for the amount of creosote absorbed by various timbers is furnished by Mr. W. B. Havelock.

IN the *Journal de Physique* for December, 1906, M. U. Schoop describes experiments for determining the lines of flow in electrolytes and the distribution of currents in accumulators. The method consists in using an analyser formed of two electrodes of spongy platinum placed close together and connected with a galvanometer; when the electrodes coincide in direction with the equipotential lines no deviation is shown. In this way the lines of the field are capable of being plotted, and a further experimental method enables the intensity of the current to be found at different points.

IT has been shown by Lord Rayleigh that there are certain cases in which an oscillation can be maintained or intensified by a periodic force of double its frequency, as, for example, a stretched string excited by a longitudinal force of half the period of lateral vibration. In the *Quarterly Journal of Mathematics*, 148 (1906), Mr. Andrew Stephenson extends this result by discussing cases in which the ratio of the frequencies, instead of being 2, is one of the numbers 1, $\frac{2}{3}$, $\frac{1}{2}$, $\frac{2}{5}$, &c., i.e. a fraction having 2 as its numerator.

IN the Manchester Memoirs, l. (190), 8, Mr. R. F. Gwyther discusses the range of Stokes's progressive waves of finite amplitude. By studying the paths of the fluid particles, the author shows that the class of wave in question is capable of indefinite propagation with uniform velocity; moreover, the motions of the particles can be determined, within a certain range, to any required degree of accuracy by means of series. There is a limit to the height of the waves when their profile shows a finite angle at the crest, and this "highest wave" is the same as that investigated by Mitchell in 1893.

THE interest taken by American mathematicians in what is done in other countries is well illustrated by Prof. Virgil Snyder's short article on the mathematical tripos of 1906 in the Bulletin of the American Mathematical Society for December, 1906. The article contains an outline of the general characteristics of the various parts of the tripos and the number and subject-matter of the papers in each part. It is illustrated by specimens of the papers reprinted by permission, one in applied mathematics from the first four days, one in pure mathematics from the higher part of part i., and one on divisions ii.–iv. from part ii. Reference is made to the fact that in part i. the "riders" generally have only a very distant connection with the bookwork.

THE "Notes in Mathematics" edited by Prof. Morley, form a pleasing addition to the dry details of class-lists and time-tables published in the Johns Hopkins University Circular, 1906, No. 9. The notes in question deal with the linear relations among the minors of symmetric determinants, by Dr. A. B. Coble, the use of a special type of rational curve (the De Jonquières curve) for the illustration of binary syzygies, by Mr. A. E. Landry, curves with a directrix, by Mr. Clyde S. Atchison, and a note on the determination of multiple points of rational algebraic curves, by Mr. H. Ivah Thomsen. These notes bear testimony to Prof. Morley's activity in organising university research, more especially seeing that the *American Journal of Mathematics* is also issued under his editorship by the Johns Hopkins Press.

A RECORD has been set up in Bendigo for the greatest depth at which gold has been found, gold ore having been struck in driving a cross-cut at 4254 feet at the Victoria quartz mine. The record find in depth previously was held by the New Chum mine, at 4226 feet.

We have received from Dr G F Kunz a collection of papers relating to the lilac-coloured spodumene, known as kunzite, from California These spodumene crystals are of extraordinary size, transparency, and beauty, and the various papers recording the remarkable discovery were noticed in NATURE in 1903 (vol lxviii, p 460)

THE magnificent collection of jadeite and nephrite presented by the late Mr Heber R Bishop to the Metropolitan Museum of Art of New York has, as stipulated in the gift, been duly catalogued The exhaustive catalogue, of which only one hundred copies have been prepared, is described by Dr G F Kunz in the Bulletin of the Metropolitan Museum of Art, 1906 It covers a thorough investigation of the subject. No copies were sold, the entire edition having been distributed amongst the important public institutions of the world

PROF W GALLOWAY, who has invented many valuable improvements in mining methods and machinery, has devised an ingenious apparatus for automatically stopping and re starting mine waggons and recently read a paper describing the invention to the North of England Institute of Mining Engineers (Newcastle-upon-Tyne, 1906) The points at which this appliance can be most usefully employed are at the weighing machine between the top of the shaft and the screens, and in front of the cage at the top and bottom of the shaft By it all the weighing on the surface and the loading and unloading of the cages have been effected automatically for upwards of a year at a colliery in South Wales

AT the *Institution of Mining and Metallurgy* a paper was read on January 17 by Mr E A Smith on the assay of silver bullion by Volhard's ammonium thiocyanate method It has recently been the practice to modify slightly the method of finishing the assay by adding sufficient ammonium thiocyanate to the check assay to intensify the red colour of the ferric thiocyanate, and to use this colour as a standard of comparison Experiments described by the author proved that, by finishing the assay in this way, a limit of accuracy of less than 0 1 per 1000 of silver can be obtained by Volhard's method Working in the ordinary way, the limit of accuracy is 0 2 to 0 3 per 1000

ATTENTION was directed by Mr Bennett H Brough in his lectures on perils underground (Journal of the Society of Arts, January 11) to the fact that, whilst from time to time some terrible colliery explosion occurred claiming scores of victims at once, every-day fatalities from falls of roof added up to a far higher total This statement is strikingly borne out by the Home Office tables of fatal accidents and deaths in and about the mines and quarries of the United Kingdom during the year 1906, of which we have received an advance proof The total number of deaths caused by explosions of fire-damp or coal-dust was fifty-four, and that caused by falls of ground was 547 Of other deaths, sixty-eight were due to shaft accidents, 329 to miscellaneous accidents underground, and 135 to accidents on the surface Altogether there were 1133 deaths from accidents as compared with 1159 in 1905

MR P E RADLEY, of 30 Theobald's Road, London has compiled and published at one penny a booklet of 64 pages dealing with metric and English weights and measures The publication may be regarded as a modern "table book," and should serve to popularise the decimal system of coinage and weights and measures generally

IN the *Times* of January 15 Dr H R Mill gives the results of a preliminary discussion of the rainfall observations of the British Isles during the past year The production of such a general summary in so short a time is at least a remarkable performance, and highly creditable to the British rainfall organisation, the preparation for final publication, after careful scrutiny, of some 4000 records will take about six months to complete Dr Mill states that the year 1906 was not remarkable with respect to annual rainfall "unless it be remarkable to coincide almost exactly with the average, the portions of the country which were unduly wet compensating for those which were unusually dry" This remark calls to mind one made by Dr Shaw, referring to the *Weekly Weather Report*, at one of the recent useful discussions at the Meteorological Office, viz that the *average* value was apparently one not very likely to occur The mean of the percentage figures given in Dr Mill's diagrams shows that the general rainfall of England and Wales was exactly the average, while that of Scotland shows an excess of 9 per cent, and that of Ireland a deficiency of 4 per cent The special monthly features were principally a wet January and dry April in the south of England, a wet May in Scotland and the north of England, a storm with excessive rainfall in the south-east half of England on June 28, a very dry summer (with the exception of a wet August in Scotland), a wet October, and heavy snowfall near the end of December

WE have received a copy of the January issue of Mr C Baker's (244 High Holborn) classified list of second-hand instruments Men of science and teachers who are requiring microscopes, surveying instruments, telescopes, spectroscopic apparatus, barometers, or other instruments or accessories will do well to examine this catalogue

MESSRS REYNOLDS AND BRANSON, LTD, of Leeds, have sent us a series of their recent issues of illustrated catalogues of chemical and physical apparatus which they are prepared to supply Every requirement of the teacher of science and of the investigator appears to have been borne in mind in preparing the catalogues which are models of clear arrangement for easy reference

MESSRS LONGMANS, GREEN AND CO have issued an abridged edition of the late Mr F W H Myers's "Human Personality and its Survival of Bodily Death" The abridgment and editing have been done by Mr Leopold H Myers The original work was reviewed at some length by Sir Oliver Lodge, F R S, in our issue of June 18, 1903, and readers may be directed to the account there given of the line of argument followed by Frederic Myers The price of the present book is 10*s* 6*d* net

AN address on the "Modern Theories of Electricity and their Relation to the Franklinian Theory," delivered in Philadelphia by Prof E Rutherford at the celebration in April of last year, under the auspices of the American Philosophical Society, of the 200th anniversary of the birth of Benjamin Franklin, is published in the official record of the celebration In his address Prof Rutherford gave a comprehensive review of the development of the conceptions which have been formed of positive and negative electricity from the time of the one fluid theory of Franklin to the present day, and briefly summarised recent views of the constitution of matter from the standpoint of the theory of electrons

OUR ASTRONOMICAL COLUMN

THE PROPER MOTION OF CASTOR.—Taking into account both the true proper motion and the orbital motion of the system of Castor, Mr. Crommelin has determined a new value for the proper motion of the centre of gravity of the system. This new value is −0·01358, +0″·120, and it represents the facts much more closely than those previously determined by Auwers and Newcomb respectively. In fact, the latter would have become entirely erroneous in N.P.D., within a few years, for they were based on the assumption that the proper motion was uniformly rectilinear, whereas the orbital motion in N.P.D. will, in a few years, be entirely reversed. It is interesting to note that the new value was obtained by taking into account the spectroscopic as well as the meridian-observation results, and that the mass ratio obtained by Dr. H. Curtis, which shows that the mass of α1 is six times greater than that of α2, is hereby confirmed (Monthly Notices R.A.S., December, 1906).

LINE INTENSITY AND SPECTRAL TYPE.—The results of an interesting investigation of compound lines shown on the stellar spectrograms obtained at the Mills Observatory, Chile, are published in No. 5, vol. xxiv., of the *Astrophysical Journal* by Dr. Sebastian Albrecht. From the spectrograms of stars of different types it was found that certain compound lines give progressive differences in the determined radial velocities as one passes from the type F to the type Mb in the Harvard classification. The investigation showed that these differences are probably due to the variation of intensity, rather than the presence or absence, of the same components of the blended line in passing from one stellar type to another. It also showed that, considering the origins of the variable lines, the physical conditions in the stars as we pass from the F (Procyonian) to the Mb (Antarian) type vary roughly in the same direction as from the sun to the sun-spots, a conclusion confirming that arrived at by Sir Norman Lockyer (Proc. Roy. Soc., vol. lxxiv., p. 53) in a paper which does not appear to have been noted by the American observers who have since dealt with this subject.

The awkwardness of having an arbitrarily chosen code, instead of self-explanatory generical names, to represent stellar types, is strikingly illustrated in the present paper, where the reader's mind is constantly taxed in trying to remember the significance of such signs as Ma, K_5M, F_8G, and so on.

SILICON IN THE CHROMOSPHERE.—At the last meeting of the Royal Astronomical Society Mr. Fowler read a paper in which he demonstrated the probable presence of silicon in the chromosphere. This element was identified by the presence of two of its strong lines, λ 6347·3 and λ 6371·6, as well-marked lines in the chromospheric spectrum. Both lines occur in the Fraunhofer spectrum, with intensities and characters 2N and 1Nd? respectively, and the latter was ascribed to iron by Rowland, who failed to find an origin for the other. Both are probably enhanced lines, and are almost obliterated in the sun-spot spectrum (Monthly Notices, No. 2, vol. lxvii.).

VARIATION OF WAVE-LENGTHS IN THE SOLAR SPECTRUM.—Whilst discussing his 1901–6 observations of the sun's rotation period Dr. Halm discovered a previously unknown "shift" in two of the spectrum lines employed. The method used at Edinburgh is that in which the difference of the interval between certain solar and atmospheric lines at the sun's centre and at the limb is measured, this difference giving the "Doppler" displacement at the limb due to the sun's rotational motion. Dr. Halm found that this interval was not the same in 1906 as in 1901, and on analysing his results further he also found some indication of a three-year period in the variation, thus giving additional confirmation to the existence of a short period in solar phenomena such as found by Dr. W. J. S. Lockyer when discussing the relations between solar and terrestrial meteorological phenomena. Dr. Halm suggests that the "shift" discovered by him may be due to difference of pressure (*Astronomische Nachrichten*, No. 4146).

MEETING OF THE AMERICAN ASSOCIATION AND ITS AFFILIATED SOCIETIES.

THE fifty-seventh meeting of the American Association for the Advancement of Science and of the societies affiliated with it was held at New York, N.Y., during the recent convocation week (December 26, 1906, to January 2), under the presidency of the distinguished pathologist Dr. William H. Welch, of Johns Hopkins University. The meetings brought together a larger number of scientific men than ever before, and it is estimated that about 1800 scientific men and women were in attendance. The meetings for the most part were held in the compact group of buildings forming the Morningside Heights property of the Columbia University, but the medical meetings of Section K (Physiology and Experimental Medicine) of the association, of the American Physiological Society, the American Bacteriological Society, and the American Society of Anatomists were held at the College of Physicians and Surgeons and at the Rockefeller Institute. The Geological Society of America and Section E (Geology and Geography) met at the American Museum of Natural History, and the Botanical Society of America and Section G (Botany) met at the Botanical Gardens. The opening meeting was held in Earl Hall, Columbia University, when the retiring president, Prof. C. M. Woodward, of St. Louis, introduced his successor, Dr. William H. Welch. An address of welcome was given by Dr. Nicholas Murray Butler, president of Columbia University, to which Dr. Welch responded.

The address of the retiring president, Prof. Woodward, was delivered at the Teachers' College on Thursday night, December 27, 1906, and was entitled "The Science of Education," a peculiarly apt topic for this meeting, since a new section, "L—Education," was founded at this time.

The addresses of vice-presidents, that is, the chairmen of sections, were extremely interesting. On Thursday afternoon Vice-president Ward, in his address before the Section of Zoology, used as his subject "The Influence of Parasitism on the Host"; Vice-president McNair, before the Section of Mechanical Science and Engineering, spoke on "Some Problems Connected with Deep Mining in the Lake Superior Copper District"; Vice-president Fisher, before the Section of Social and Economic Science, spoke on the topic "Why the *Laisser-faire* Doctrine Failed"; Vice-president Rice, before the Section of Geology and Geography, spoke on "The Contributions of America to Geology"; Vice-president Sedgwick, before the Section of Physiology and Experimental Medicine, spoke on "The Expansion of Physiology"; Vice-president Eichelberger, before the Section of Mathematics and Astronomy, had as his title "Clocks—Ancient and Modern"; Vice-president Mabery, before the Section of Chemistry, spoke of the "Education of a Professional Chemist"; Vice-president MacCurdy addressed the Section of Anthropology on the subject of "Some Phases of Prehistoric Archæology"; Vice-president Crew, before the Section of Physics, spoke on "Fact and Theory in Spectroscopy"; and Vice-president Smith, before the Section of Botany, under the title "Problems in Plant Pathology."

One of the most interesting and important features of the meeting was the holding of a number of joint sessions between different societies and sections. For example, the afternoon of December 27 was devoted to a symposium under the auspices of Section K (Physiology and Experimental Medicine) at the College of Physicians and Surgeons on the subject of protozoa as factors in disease, a discussion in which both the pathologists and the botanists joined. On the following day a joint meeting of the Society of Zoologists and the Sections of Zoology and Botany was held for the reading of papers on heredity in plant and animal breeding, and on that day Section K held a joint meeting with the Society of American Bacteriologists. There was also a general discussion under the auspices of the American Society of Naturalists on the general topic "The Biological Significance and Control of Sex." On the same day a new Entomological Society of America was founded, with nearly 200 members, and a public lecture was delivered under its auspices by Dr.

Wm M Wheeler, on "The Polymorphism of Social Insects."

On Saturday, December 29, a general meeting and luncheon was given at the College of the City of New York, where lectures were given on "The Effort to Save Niagara," by Dr John M Clarke, and "On the Industries of Niagara," by Prof C. F Chandler In the afternoon a general meeting was held at the American Museum of Natural History to attend the ceremonies connected with the unveiling of the busts of American men of science presented to the museum by Mr Morris K Jesup Five-minute speeches of presentation were made by Dr H C Bumpus, Hon Joseph H Choate, Dr S Weir Mitchell, the representative of the German Ambassador, Dr C Hart Merriam, Dr N L Britton, Dr R S Woodward, Dr Arthur T. Hadley, Dr Hugh M Smith, Dr W K Brooks, and Dr H F Osborn A reception was given at the museum in the evening by the trustees of the museum and the New York Academy of Sciences, with an exhibition of scientific progress by the academy, including a demonstration and short addresses

The most important actions taken by council and by the association at the New York meeting were as follows —(1) The addition of a new section to the association, viz L—Education, (2) the change of the title of Section H from "Anthropology" to "Anthropology and Psychology", (3) a standing committee of fifteen on seismology was appointed, (4) a Darwin memorial committee of ten was appointed to consider the manner in which the association may suitably commemorate the fiftieth anniversary of the publication of the first edition of "The Origin of Species," and this committee was authorised to make overtures to the British Association in order to ascertain whether joint action in this matter cannot be taken (5) the permanent secretary was authorised to publish hereafter in the official programme of the association all the programmes of all the affiliated societies, whether holding joint sessions with the sections of the association or not, (6) Section E and other sections desiring to do so were authorised to hold a summer meeting during the summer of 1907, (7) a memorial was presented to Congress urging the passage at the present session of the Bill creating forest reserves in the White Mountain region and in the Lower Appalachian region

In accordance with the policy adopted of recent years, the general committee chose as the place of next meeting the city recommended by the last general committee namely, Chicago, and recommended to the next general committee that the meeting of 1908–9 should be held in Baltimore A cordial invitation was received from the president of the University of Chicago, from the Field Columbian Museum and from the Mayor of the city, and also from the president of Johns Hopkins University, of Baltimore The alternation of eastern and mid-western meetings appears to be, on the whole, satisfactory, although the eastern meetings have been much more largely attended Chicago, however, is a great scientific centre, and is so easily accessible by rail that the next meeting bids fair to be a large one

The officers elected for the Chicago meeting were as follows —President, Prof E L Nichols Cornell University, Ithaca, N Y , *vice-president and chairman of Section A* (Mathematics and Astronomy), Prof E O Lovett Princeton University, Princeton N J , vice-president and chairman of Section B (Physics), Prof Dayton C Miller, Case School of Applied Science, Cleveland, Ohio, vice-president and chairman of Section C (Chemistry), Prof H. P Talbot, Massachusetts Institute of Technology, Boston, Mass , vice-president and chairman of Section D (Mechanical Science and Engineering), Prof Olin H Landreth, Union College, Schenectady, N Y , vice-president and chairman of Section E (Geology and Geography), Prof J P Iddings, University of Chicago, Chicago, Ill , vice-president and chairman of Section F (Zoology), Prof F B Wilson, Columbia University, New York, N Y vice-president and chairman of Section G (Botany), Prof C E, Bessey, University of Nebraska, Lincoln, Neb , vice-president and chairman of Section H (Anthropology) Dr Franz Boas, American Museum of Natural History, Central Park, New York, N Y , vice-president and chairman of Section I (Social and Economic Science), Dr John Franklin Crowell, c/o *The Wall Street Gazette*, New York, N Y , vice-president and chairman of Section K (Physiology and Experimental Medicine), Dr Ludwig Hektoen, University of Chicago, Chicago, Ill , vice-president and chairman of Section L (Education), Hon Elmer Brown, U S Commissioner of Education, Washington D C

SOME RECENT WORK OF GEOLOGICAL SURVEYS

THE Summary of Progress of the *Geological Survey of the United Kingdom* for 1905 (London H M Stationery Office, 1906, price 1s) contains new information regarding the granites of Cornwall and the results of subterranean vapour-action on their flanks The associated elvan-dykes are now recognised as cutting the granite, and not as offshoots from the more coarsely crystalline mass The Ordovician beds of South Wales are being divided into zones, under the care of Mr Strahan We may note that the spelling "Llandilo" is officially accepted At the same time, the Coal-measures of South Wales continue to receive close attention, and Messrs Gibson and Cantrill describe the progress of the search for coal beneath the Permian and Trias of the English Midlands Mr Flett's account of the Lewisian rocks that have been recognised within the area of the Moine gneisses in northern Scotland shows that the ancient intrusive gneisses are accompanied by still older rocks of sedimentary origin, which have been metamorphosed by them Following Dr Peach, the occurrence of an unconformity between this older complex series and the Moine gneisses is regarded as extremely probable (pp 103, 166 &c) Mr Howe furnishes a summary of the work done in the museum at Jermyn Street on the samples of road-metal tested in Mr Lovegrove's machines at Hornsey The full results are now available in a separate work (see NATURE, vol lxxv , p 220)

The Geological Survey also issued in 1906 a colour-printed edition of Sheet 110 of the English map, with the superficial deposits represented, and an accompanying memoir of 138 pages on "The Geology of the Country around Macclesfield, Congleton, Crewe and Middlewich" (price 2s 6d) The only things that we miss in this memoir are photographic illustrations to show the contrast between the drift-covered plain of Cheshire and the scarped and broken country leading northwards from Mow Cop Even a vignette of Moreton Hall, and another of the spoil-heaps of a coal mine, might express the social and industrial contrast, which is so well known to road-travellers between Chester and the Pennine Chain The "general description," however, makes good amends from the point of view of structural geology The details of the superficial deposits are the newest feature in the memoir, and the glacial beds are regarded as the product of an ice-sheet about 1100 feet in thickness (p 79) The marine shells found in the high-level gravels "may well have been caught up by the ice in its passage over the Irish Sea" Examples of these occur east of Macclesfield at a height of 1200 feet above the sea But Mr T I Pocock, who treats of this area in the memoir, believes that the shelly sands formerly to be seen under Macclesfield itself (p 84), at a height of about 450 feet, may have been deposited in a shallow sea The perfect state of preservation of large numbers of the molluscan remains and the absence of glacial indications in the beds, influence him in this opinion, which is quite in accordance with what is admitted in countries outside the British Isles At home, however, it is certain to be questioned as is also the dim suggestion of an inter-Glacial epoch in the succession of events tabulated upon p 88 The economic geology of the area is dealt with in chapter ix

Earlier in the year, Mr G Barrow's memoir on "The Geology of the Isles of Scilly" (price 1s) was issued to accompany a convenient map which includes the whole group in a single sheet Here photography has freely been called in, and the relations of the isles to human interests are well touched on Mr Flett's petrographic notes appear,

happily, in connection with the description of the rock-masses in the field An outlier of gravel (p 15), "largely composed of Chalk-flints and Greensand-chert," forms a cap on the eastern promontory of St Martin's, and may be a relic of a river-gravel, spread from Dartmoor over a continuous land-surface in Eocene times The old pre-Glacial beach, now near sea-level, has been raised at least 40 feet, and again lowered by that amount, since its formation (p 33), the evidence of this comes from the mainland, but is sufficiently conclusive The warping in the beach itself may be brought to the attention of those who are captivated by the theory of fluctuations in the volume of the sea rather than by that of recent movements of the land

Part iv of the *Administration Reports of Ceylon* for 1905 includes one on the Mineralogical Survey, by the director, Dr A K Coomaraswamy This raises a number of points of great interest to the petrographer as well as the mineralogist The graphite of Ceylon is regarded as a product of vein-filling processes following the reasoning of Weinschenk—here styled, as so often happens, Weinschenck If, however (p E3), the crystalline limestones of the district are organic, the graphite may possibly have had "an indirect organic origin" The similarity of the deposits in Ceylon to those of Quebec, which are directly associated with limestone, is not so great as Osann has recently suggested The discovery of thorianite by the director has led to investigations in a number of valleys (p E 6), but, knowing the country intimately, Dr Coomaraswamy does not believe that it would be practicable to divert the courses of the streams to facilitate the raising of the material An illustrated account is given of the native method of dredging for gems, and there is a fine plate showing the weathered surface of limestone associated with bands and lumps of granulite A parallel to this "interstreaking" of the two rocks can surely be found in the west of our own islands where the "granulite" is clearly an invader in the limestone This report, so closely and simply written, provides more agreeable reading than many ambitious volumes with wide margins and encyclopædic information

From the *New Zealand Geological Survey* we have received Bulletin No. 1, describing the geology of the Hokitika sheet, by J M Bell and Colin Fraser (pp xii+102, 1906) Some of the topographical work has to be carried out by the Geological Survey, and maps are usefully added in an envelope at the end of the bulletin The area described lies in North Westland, and contains both alluvial gold and coal The relics of formerly extensive glaciers, with snowy gathering-grounds at a height of about 5500 feet above the sea, afford especially interesting features in a latitude of 43° S One of these narrow shrunken glaciers is shown in the illustration here selected (Fig 1), and the memoir abounds in photographic views which will appeal equally to the geographer and the geologist. It should have been noted, perhaps, by the authors that some of these views represent more than the perpetual snow. On p 21 it is suggested that the glaciation began to spread from the new mountain-range "during or perhaps just following Lower Cretaceous times." On the next page this is, we think, corrected by the statement that "glaciation started in Miocene time" The great advance of the ice, reducing the island to the condition of Greenland, probably took place in the early Pleistocene Whether this was due entirely to the upheaval of a mountain-chain across the direction of the prevalent winds is left an open question We gather that the great mountain-building movements were of early Eocene age

The authors have no doubt as to the excavating power of the glaciers in the past, and quote the forms of the lake-bottoms in support of their conclusions. The petrology is illustrated by a striking series of enlargements from rock-slices, reminding one, on a still bolder scale, of the pioneer work of the late Sir R Daintree. Nephrite (p 69) is found occurring as segregations in talc-rock or talc-serpentine-rock, the lumps being from about 1 inch to 2 feet across, these are pointed out (p 99) as of economic value On p 93 we have the interesting suggestion that boulders of "grauwacke" in Butcher's Creek supply sufficient ferrous carbonate to act, when they decompose, as precipitants of gold in the solutions permeating the surrounding gravels These boulders were examined chemically, owing to the greater richness of the gravel round them as compared with that round boulders of other rocks. Another remarkable record is the discovery of platinum in quartz-veins (p 96) The whole bulletin, with its introduction on the botany, soil, climate, and communications of the area, shows that the survey has a high conception of its duties in carrying on the scientific investigation of New Zealand

The *Annual Report of the State Geologist of New Jersey* for 1905 shows the local survey in cooperation with that of the United States, and even competing with it in the

FIG 1—Grave Creek Glacier, with Mount Walter (6350 feet) at the back.

production of geological maps on a large scale (p 4). As is now the case with most surveys, economic observations occupy an important place, and it is doubtless found that the necessity for close scrutiny and all-round questioning which such inquiries involve reacts favourably on the character of the more purely scientific work In New Jersey, however, the Geological Survey goes outside ordinary lines, and deals, for instance, with water-supply and coast-protection from an engineering point of view Mr Berry describes (p 135) the Cenomanian flora of the Magothy beds at Cliffwood Messrs. Parmelee and McCourt contribute ninety pages on the nature and uses of peat, and on the peat-deposits of the State, with a general bibliography

The recent work of the *United States Geological Survey* has been dealt with lately in a special article (NATURE, December 20, 1906, p 182) Mr Calhoun has now issued a professional paper on "The Montana Lobe of the Keewatin Ice-sheet," which contains interesting details (p 40, &c) as to the influence of the main ice-sheet on the course of the Missouri River, Students of dry river-courses in glaciated areas will find the Shonkin Sag of interest, a channel with characteristically fresh surface-

features (Fig 2), and cut to a depth of 600 feet across and not down, the slope of a hillside for a length of eighty miles (pp. 12 and 43). This is explained by the action of an overflow-stream from a lake held in between the ice-front and the hills Parts of several pre-Glacial stream-outs were utilised in its course

The work of the *Geologische Reichsanstalt* of Vienna may conveniently be touched on in this article In vol lvi of the *Jahrbuch* of this institute (May, 1906, p 298) Dr Stuchlik attributes a lateritic origin to the "bunte Mollasse" of the Oligocene of southern Bavaria, and urges that the red ferruginous material was washed down from tropical deltas into a shallow sea. B Granigg's paper (p. 367) on the Ober-Möltal in Carinthia contains some observations on the origin of serpentine, and it is instructive to note that the intrusive masses from which this rock has been produced have metamorphosed the adjacent mica-schist and quartzite in very various degrees Contact-alteration is at times hardly perceptible, a fact that may be taken into account in the discussion on the origin of the South African diamantiferous material In the *Verhandlungen* of the Reichsanstalt, 1906, pp 146–164, Dr F E Suess gives a general account of the geology of the complicated district in the environs of Brünn The

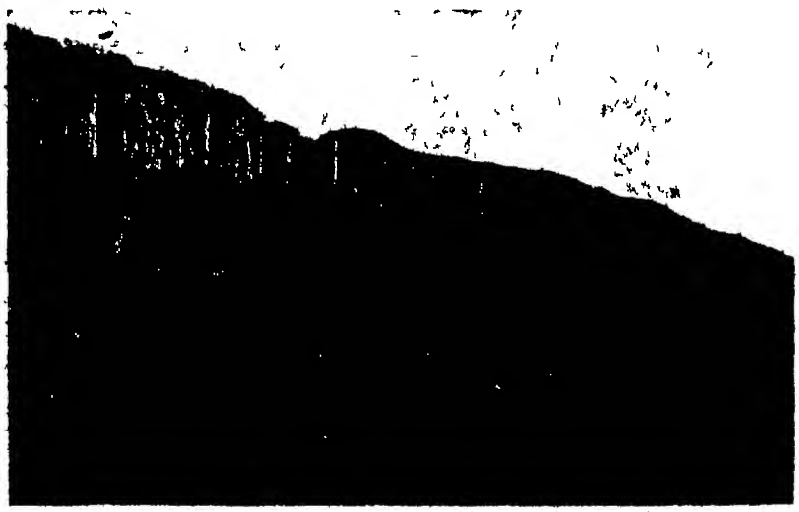

FIG 2 —The wall of the Shonkin Sag, a valley of glacial drainage in Montana

sheet of the geological map described includes part of the ancient Bohemian plateau on the north-west, and part of the Cainozoic foothills of the Carpathians on the south-east The picturesque and varied scenery on the old highway from Hungary to Prague is recalled to us in this lucid memoir Brünn, little visited as it is, should clearly be an exceptional centre for the study of geology The Ortler group furnishes W Hammer (p 174) with material for a discussion of Termier's views on Alpine structure Dr Kossmat (*Jahrbuch der k k Reichsanstalt* 1906, p 274) similarly finds himself involved with Termier and Lugeon in the "Gebiet zwischen dem Karst und dem Zuge der Julischen Alpen" A specialised congress on Alpine structure, with months of field-excursions, would be needed for the answering of all these questions, but even then the new views daily propounded would effectually overwhelm the answers M Vacek (*Verhandlungen*, 1906 p 203) is allowed free scope for a highly controversial paper on the basin of Graz, in which he compares the "green beginner" in geology, who rushes into tectonics, to a stutterer delivering a public speech The name of the specially "green" one is presently shouted across the barriers of this scarcely edifying tourney The geological sections given are, of course, of considerable interest, and show a country rich in transgressions and unconformities Vacek points out the need for considering the isolated masses of Palæozoic and Mesozoic sediments in relation to the geography of the times when they were laid down Thus in many cases they were deposited in gulfs running along the hollows of an ancient crystalline series The author strips away these sediments, and seeks to trace the surface of a central Alpine land-mass denuded in pre Palæozoic times G A J C

OCEANOGRAPHICAL RESEARCH

THE Prince of Monaco presided at the formal opening of the Scottish Oceanographical Laboratory at Edinburgh on the afternoon of Wednesday, January 16 A distinguished gathering of representative naturalists from the leading cities of Scotland took part in the ceremony On the motion of the Lord Provost of Edinburgh, the Prince of Monaco was called upon to take the chair A brief explanatory statement of the genesis and development of the laboratory and of the end aimed at was given by Mr W S Bruce, the leader of the Scottish Antarctic Expedition and the founder and director of the laboratory He showed how Scotland might be regarded as the cradle of oceanography, Edinburgh having been associated with the study of the oceans for a longer period than any other place in the world The gathering together and arrangement of the material had been going on for years, and represented the work of eight scientific expeditions In many respects it was an absolutely unique collection The place it was now in was essentially a workshop for oceanography, and Mr Bruce appealed to the people of Scotland to support this movement to place oceanographical research on a permanent footing There were men able and willing to do the work if once the laboratory were properly established and affiliated to the great teaching institutions of the country

In a short address the Prince of Monaco paid a high tribute to the admirable work which had been accomplished by Mr Bruce and his companions in the Antarctic seas Their expedition had been probably the most fruitful of all the expeditions carried out about the same time and yet by far the most economical Seven other speakers, representing various interests, spoke as to the claims Mr Bruce's new venture had on the people of Scotland Sir William Turner referred to the close connection which the University of Edinburgh had had with the *Challenger* expedition and with later expeditions of a like character Dr Dobbie said that the seals and birds which the Scottish Antarctic Expedition had presented to the Royal Scottish Museum were probably unsurpassed by any like collection in any museum of the kingdom, and that other museums had greatly benefited through the generosity of Mr Bruce Dr Horne, as representing various scientific societies made special reference to the geographical knowledge which had been gained by the staff of the *Scotia*, to the practical sympathy which the Scottish Geographical Society had taken in the expedition and to the generous manner in which the Royal Society of Edinburgh in spite of its straitened means, had undertaken the publication of the memoirs describing the results Prof Arthur Thomson, as representing other Scottish universities directed particular attention to the character of the Oceanographical Laboratory as a place where a man could train himself for oceanographical work Mr Henry Coates of the Perthshire Society of Natural Science commented on the value of the collections in the laboratory being arranged as a regional museum Dr Rottenburg of Glasgow, and Mr Robert M Vitie of Edinburgh expressed their sympathy with a project which seemed to be a natural consequence of the Antarctic Expedition, the success of which had rejoiced the hearts of the many who had been interested in it

The laboratory occupies a low one storied building on the north side of the Surgeons' Hall There are four rooms, the largest of which is filled with cases stored with specimens from the Arctic, while another contains specimens from the Antarctic Each case is devoted to a particular group of animals, crustacea, fishes, molluscs, sea-urchins &c, systematically arranged, with the memoirs and papers describing them placed on the lower shelf One interesting case is arranged bathymetrically, the typical animals of different depths being placed on corresponding shelves In the Antarctic room special cases are devoted to special regions, such as the Weddell Sea Scotia Bay, &c, or to different islands, the South Orkneys, Gough Island the Falklands, and so on One interesting specimen in the collection is a large granite boulder, ice-marked, weighing 3 or 4 cwt, which had been dredged up from a depth of 1775 fathoms in lat 62° 10′ S and long 41° 20′ W The whole collection, Arctic and Antarctic represented the gatherings of the scientific work of five vessels, the *Balaena*, the *Windward*, the *Blencathra*, *Princess Alice II* and the *Scotia* Photographs of these and of interesting scenes during the *Scotia's* voyage decorated the walls At the present time many of the specimens are in the hands of the naturalists who are working up the various groups, while the larger animals are for the most part distributed throughout Scotland in various museums There are many duplicates which should prove useful in effecting exchanges with other similar institutions and so gradually increase the value of the Edinburgh collection

The inauguration of the Scottish Oceanographical Laboratory was the first of a series of public and semi-public functions at which the Prince of Monaco was the leading figure On the evening of January 16 he was the principal guest at the dinner of the Royal Society Club Lord Kelvin presided and Prof Geikie acted as vice-chairman On Thursday, January 17, the Prince received the degree of Doctor of Laws from the University of Edinburgh On the evening of the same day he delivered an address on the exploration of the high atmosphere before the Royal Scottish Geographical Society Prof Geikie, president of the society occupied the chair, and introduced the Prince as one well known as an enthusiastic devoted and successful student of natural science His investigations had been conducted on a scale which had only been rivalled by Government expeditions sent out by great nations For at least twenty-five years he had traversed the ocean in search of knowledge He had established a great oceanographical institute at Monaco, a weather bureau, and a museum, and last year he endowed at Paris an oceanographical institute at a cost of not less than 160,000*l* The president then handed to the Prince the gold medal which the society had awarded him in recognition of his scientific work

In the course of his address, the Prince said that in the last few years the improvements in the manufacture of steel had made it possible to fly kites at great heights carrying self registering apparatus Also the India-rubber industry had enabled balloons carrying self-registering apparatus, to be sent to altitudes hitherto inaccessible Through the liberality of the German Emperor a great establishment had been set up at Lindenberg for the systematic investigation of the upper-air meteorology This was over the land In 1904 the lecturer had become interested in the subject, and he began to make plans for investigating the problem over the sea To reach great heights it was necessary to attach to the line or wire a series of kites at intervals and if no layers of calm air were encountered a very great height could be reached and the kite kept there by the vessel moving with a speed of not less than 7 metres per second There were many difficulties on board ship due to complications of wind distributions in the different layers After a season's work with kites in the Atlantic the Prince resolved to try the *ballons-sondes* The method first adopted was to use two light india-rubber balloons filled with hydrogen The one carried the self-registering apparatus while the other and more inflated balloon was attached to it, and aided the ascent to the required height At this height the upper balloon burst, and the lower balloon with its instruments descended as a parachute, and hovered over the sea so long as the float at the end of the stray line touched the surface of the water This could be seen at a distance of eight or ten miles The bursting of the balloon was somewhat indefinite, and an improvement was subsequently effected by means of which the one balloon was released altogether at the desired height This was done by means of a current from a small dry cell set in action when the pen of the barograph on the lower balloon touched a conductor set at the pressure corresponding to the desired height Also by use of a formula taken in connection with the observed ascent of the system, the line of descent of the "*ballon parachute*" could be approximately calculated, and the ship steered for the place By means of apparatus of this kind pressure and temperature curves had been brought back from a height of 7500 metres in latitude 78° 55 In the high latitudes the experiments had been greatly interfered with by fog The drift of air in still higher regions had been studied by means of pilot balloons, which had been followed through the telescope of a theodolite to heights of nearly 30,000 metres These indicated that in latitude 80° north, at a height of about 13 600 metres, there were at times winds blowing with a velocity of 60 metres per second, or 130 miles per hour The results of several cruises had shown that "if the principal States of the world were willing to diminish a little the expense of international quarrels by submitting them to the judgment of a tribunal less costly than that of war, and if they preserved more resources for the veritable interests of humanity, it would be possible with powerful means very soon to know the laws of meteorology, the key to which seemed to be found in the higher atmospheric regions"

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE — The voting on the proposed reform of the mathematical tripos will take place on Friday and Saturday February 1 and 2

The placet executive committee has issued a letter to non resident members of the Senate pointing out that "the proposed scheme is supported by a large majority of the resident members of the Senate, a majority which includes eight heads of houses, more than thirty professors, all the official university teachers of mathematics, and the whole mathematical staff of several of the larger colleges Moreover, the principles of the reform have already been approved by the Senate It is, however, impossible for the reform to be carried into effect unless it is supported by the votes of a large number of non-residents The rejection of the proposed reform would be a great calamity for the future of the Cambridge School of Mathematics Further, the precedent established by the reversal of a decision already made would be a serious menace to the practical working of the government of the University"

THE citizens of Montreal resolved at a meeting on January 16 to raise 200,000*l* for an endowment fund for the McGill University Mr Robert Reford promised to contribute 10,000*l* Lord Grey presided, and Lord Strathcona was also present at the meeting

A COURSE of eight lectures on "Certain Fundamental Problems in Physiology Common to Animals and Plants," to be given at University College, London by Dr W M Bayliss, F R S, commenced on Wednesday, January 23 The lectures are open to all students of the University of London

MR G P DARNELL SMITH has been appointed assistant director of technical education and manual training to the Board of Education, Auckland, New Zealand Mr Darnell Smith has been on the staff of the Merchant Venturers' Technical College, Bristol, since September, 1892, and some time ago he was promoted to the post of assistant professor of chemistry in the college

THE Duke of Northumberland on January 17 opened the new Royal Grammar School at Newcastle-upon-Tyne, which has been built by the governors at a cost of 60,000*l* to take the place of an older building In his inaugural address the Duke of Northumberland said, with regard to recent elementary education, we have probably over-

weighted the coach Small brains have been strained further than they should be, a smattering rather than a real grounding in knowledge, and a "cramming" rather than a forming of character, have been given He hopes that the revival of the interest in secondary education is a sign that we are going to mend our ways in these directions My own belief, he continued, is that the proper form for education to take is to teach very few subjects in the elementary schools and to teach them thoroughly Then, instead of wasting time in making a level of mediocrity, let promising children be taken out of the elementary schools, and, when they are really likely to profit by superior and special instructions, bring them into secondary schools All the population who show that they are able to profit by the advantages of secondary education should receive it Some of the money spent on elementary education might be saved and spent on technical education

PROF SCHUSTER has offered to the University of Manchester during the next three or four years an annual sum of 350*l* as the stipend of a reader in mathematical physics The council and senate have accepted with great gratification Prof Schuster's generous gift, and the post will be instituted forthwith The reader will be attached to the department of physics His primary duty will be the promotion of research in the subject of mathematical physics, but he may also be called upon to give a course of lectures on the subject Prof Schuster in a letter to the Vice-Chancellor, gave his reasons for making his offer, as follows —"I have been watching for some time with considerable apprehension the growing separation between the subjects of mathematical and experimental physics This separation followed perhaps naturally on the rapid growth and exceptional success of the experimental side during the last twenty years, but it cannot, in my opinion, fail to be detrimental to the further progress of the science I have been trying in the physics honours school of our university to give equal weight to the two branches of the subject, and the offer I now make is intended to emphasise the close connection which should exist between experimental and theoretical work I believe that at the present moment the foundation of such a readership as I contemplate would be of advantage to science generally and to our school of physics"

MR E B SARGANT, education adviser to the High Commissioner of South Africa, read a paper at the meeting of the Royal Colonial Institute on January 15 on federal tendencies in education Among other subjects of educational importance, Mr Sargant dealt with movements especially characteristic of higher education, such as the unceasing stream of young men of good circumstances which flows from the various parts of Greater Britain through our ancient universities a movement which, in the case of Oxford, was so powerfully reinforced by the bequest of the late Mr Rhodes From the point of view of our larger national character, it is difficult to put too great a value upon the influence exerted by such a circulation of students through the heart of our higher educational system He then spoke of the need of reproducing this kind of education in the colonies themselves and said that our great public schools and colleges ought to realise that at no distant date they may themselves be asked to extend into Greater Britain Mr Sargant also discussed the federal stimulus in education, of which the London University, in its purely examinational aspect, must be considered to be a first cause, and observed that, from an Imperial point of view, the University of London has centred the thoughts of many of our fellow-subjects in all parts of the British Dominions upon the value of some unity of educational aim, even though it may be only a unity of standard In the discussion which followed, Sir A Rücker pointed out that in any dominion of the Crown it is possible for a candidate to test himself in order to see whether he has attained a standard equal to that which is attained by a good English schoolboy or undergraduate

PROF RUDOLF TOMBO, jun of Columbia University has compiled an interesting set of registration statistics concerning the principal universities of the United States The statistics are published in the issue of *Science* for December 21, 1906 Comparing the figures for 1906 with those of the preceding year, it is seen that California, Leland Stanford, Johns Hopkins, North-Western, and Columbia universities have all suffered a decrease in attendance The greatest gains have been made by Pennsylvania, New York, Indiana, Missouri, Syracuse, Virginia Nebraska, Ohio, Cornell, Illinois, Chicago, and Michigan universities Harvard and Yale with a few other universities have remained stationary in numbers Examining the numbers of students taking different faculties, most of the institutions this year show an increase in enrolment in the arts department This is true, so far as men are concerned, of every institution in the table, with the exception of Johns Hopkins and Wisconsin, though several universities for a number of years have registered continual losses in their arts departments these losses being in many cases due to corresponding gains in the scientific schools Prof Tombo says a reaction has apparently set in in this direction, at least at a number of institutions At Princeton, for example, the number of arts students has increased from 629 to 758 at Yale from 1323 to 1350, at Columbia from 557 to 606 whereas the number of science students at the same institutions has decreased from 624 to 484 in the case of Princeton from 1028 to 929 in the case of Yale, and from 560 to 524 in the case of Columbia At Harvard the discrepancy is even greater The largest gain in the number of science students has been made by Illinois (from 880 to 1020)

THE *Times* recently published some details of the work done by the London County Council Education Committee in the direction of the proper training of children on the physical side With regard to hygiene and medical work, the head teachers of the schools are instructed to give attention to such questions as ventilation the scrubbing of floors, and the inspection of the "offices" Children who come to school dirty are washed or if further purification is needed they are sent home Notification is made to the medical officer when any child attends school suffering from an infectious disease or after coming from an infected home Defective children receive special attention, and lists are made in order that they may be medically inspected The staff of trained medical nurses now numbers thirty two The nurses are constantly at work visiting the schools, where they closely examine the children, confer with the teachers, schedule the unclean and those suffering from skin diseases and generally continue the work of the teachers in these matters The education committee has its own medical officer, an assistant and twenty three other qualified medical men or women, who give a half or a quarter of their time These medical officers if necessary exclude a child from school and recommend the temporary closing of the school itself in case of extensive prevalence of infectious disease In examining the children reported to be defective, if they find that the defect is such as to make it desirable that the child should be remitted to a "special" school, they recommend accordingly The question of bad teeth is not overlooked Much care is devoted to cases of defective sight Care is exercised in seeing that no child's sight is strained and the number of children who visit the hospitals for treatment is very large Physical exercises, including all that modern scientific and practical experience can suggest as best fitted for the pupils, form an important part of the curriculum of every school The exercises are health-giving, and are enjoyed by both boys and girls Games are also encouraged and even organised by the voluntary efforts of the teachers Most schools have their athletic clubs and the Council is now making a new departure by providing playing grounds

SOCIETIES AND ACADEMIES

LONDON

Royal Society, November 15, 1906 —"Calcium as an Absorbent of Gases, and its Applications in the production of High Vacua and for Spectroscopic Research" By Frederick **Soddy** Communicated by Prof J Larmor, Sec R S

By means of a special electric furnace surrounded by a porcelain tube and enclosed within a glass tube it has been found possible to heat reagents *in vacuo* in sealed

soft glass apparatus, to a far higher temperature than the softening point of glass Calcium heated in this manner is, under suitable conditions, an absorbent of all the known gases, with the exception of those of the argon group Provided the initial gas-pressure does not exceed a few millimetres of mercury, all the common gases are rapidly and completely absorbed by calcium between 700° C and 800° C, and a vacuum attained through which the electric discharge cannot be forced Arndt (*Ber d d Chem Gesell*, 1904, xxxvii, 4733), in an investigation of the melting point of calcium, noticed that the calcium volatilised freely below its melting point when heated in a vacuum of 1 mm mercury, and the vapour reacted energetically with the oxygen and nitrogen of the residual air, producing a great improvement in the vacuum He did not investigate the behaviour of other gases

This behaviour of calcium is all the more surprising because in ordinary circumstances it shows a great disinclination to react, and may be heated in a tube filled with air at atmospheric pressure to a very high temperature without causing much absorption A low initial pressure of the gas and volatilisation of the metal are essential in using calcium as an absorbent Barium and strontium behave in a manner very analogous to calcium In the case of hydrogen and its compounds, the absorption becomes more complete, and the vacuum improves when the calcium is allowed to cool owing to the hydride possessing an appreciable tension of dissociation at the high temperature

The high vacua readily produced by the absorption of residual gases by calcium are at least equal to the highest attained by any other process By filling the apparatus with mercury after the action of the calcium, and compressing any residual gas several hundred times into a tiny spectrum tube, it was found that the vacuum was still so high that the spectrum tube was of high resistance and fluoresced brightly under the discharge, showing a faint hydrogen spectrum Since argon is not absorbed, the air must be first removed from the apparatus by means of a Fleuss pump and by replacement of the last traces with some argon-free gas, before the calcium is brought into action The condensed gases evolved from the apparatus on heating usually suffice to replace the last of the air during the mechanical exhaustion The calcium, being a good conductor of electricity, may be readily heated to the required temperature within the sealed glass vessel by induction through the walls from an alternating circuit outside the vessel The special feature characterising the new method is the rapid and complete absorption by the calcium of the gases condensed on the walls, and in the electrodes, &c, of the apparatus being exhausted as soon as these are expelled by heating These gases, known technically as "film gases," consist largely of hydrogen and carbon compounds, and cause most of the difficulty experienced in practice for they readily re-condense and introduce a kind of steady vapour pressure within the apparatus, greatly increasing the time required for exhaustion

In the apparatus usually employed for experimental work a porcelain tube with an external screw-thread is wound with a platinum resistance wire through which a current is passed A porcelain test-tube containing the reagent is slipped within this furnace tube, which in turn slips within a wider porcelain tube, which again slips within the external glass tube provided with platinum wires sealed through the glass for conveying the heating current This tube is then sealed to the apparatus to be exhausted

In one form of apparatus for heating the calcium by induction, a calcium disc is bored with central hole through which a short bundle of soft iron wires pass Two porcelain crucible lids bored with central holes fit over the calcium disc, the ends of the iron wires projecting beyond the lids This arrangement is slipped into a glass tube with the axis of the iron core at right angles to the length of the tube A coil of soft iron wire is cut at one point and bobbins of wire slipped over the two ends, which are then brought opposite and close to the ends of the iron core within the glass tube On exciting the bobbins with an alternating current of high periodicity (200 to 400 periods) a current of the order of a kiloampere is induced in the calcium disc, heating it to the required temperature

The phenomena when successive quantities of air are admitted into an apparatus containing heated calcium are of special interest, for all but the 1 per cent of argon is rapidly absorbed, and in this way the minimum quantity of argon necessary to carry the discharge and show a spectrum has been determined Below 1/50 mm argon does not conduct, at this pressure the green and orange lines are faintly visible, at 1/25 mm the reds appear; at 1/2 mm the spectrum tube has a resistance equivalent to an alternative air gap of 5 mm., while at 1 mm. pressure the tube is still brilliantly fluorescent With helium, introduced into the apparatus as a mixture of oxygen with a known small quantity of helium, the tube is non-conducting to the discharge at pressures below 1/20 mm of helium when every trace of other gases is absent In presence of hydrogen or oxygen one-hundredth part of this amount is sufficient to show the D_3 line of the helium spectrum The conclusion is drawn that the inert monatomic gases in the absence of every trace of polyatomic gases show a great disinclination to conduct the discharge, and this accounts for many isolated facts familiar to workers with high vacua The rapid "running out" of spectrum tubes filled with inert gases is due, not to the absorption of these gases, but to the absorption by the electrodes of the traces of hydrogen, &c, always present initially or introduced by the electrodes (compare Skinner, *Phil Mag*, 1906 [vi] 12,481) When this has occurred the pure monatomic gas no longer conducts The fact observed by Lord Blythswood and H S Allen (*Phil Mag*, 1905 [vi] 10,497), that an X-ray bulb may be readily exhausted from atmospheric pressure of air to a "vacuum so good that the tube had to be heated to allow the discharge to pass through it," by the use of charcoal cooled in liquid air according to the method of Sir James Dewar, at first seems inconsistent with the fact that seventeen parts per million of the air, consisting of helium and neon, remain unabsorbed, and the residual pressure must therefore be about 1/75 mm The explanation is to be found again in the disinclination of these monatomic gases to conduct when pure For this reason the electric discharge test of the goodness of a vacuum is altogether misleading, for with the inert monatomic gases pressures within the range of the mercury barometer appear to be high vacua The great power of calcium in absorbing every trace of carbon dioxide, hydrogen, water vapour, hydrocarbons, &c, derived from impurities in the apparatus, and from the lubricating grease of stop-cocks, makes it a powerful aid to the methods of spectroscopic research

Appendix—"Results of Gauging High Vacua by the Evaporation Test" By A J **Berry**.

The degree of high vacua produced by different processes may be gauged by the rate of evaporation of liquid air in a Dewar vessel exhausted by the process The same globular vessel of about 1 litre capacity, silvered internally, was exhausted (1) by the mercury pump, (2) by the use of cooled charcoal from atmospheric pressure, using two successive quantities of charcoal, (3) by cooled charcoal after the air had been first removed by a mechanical pump It was to be expected from the conclusion drawn in the preceding paper that the degree of vacuum obtained in the second test would be much inferior, tested by the evaporation method, to that obtained in the third The expectation was fully borne out by the experiments The liquid air evaporated at the rate of 898 grams in four days in the vessel exhausted by the second method, which was rather faster than in the first method, when the vacuum was produced by a mercury pump The vacuum produced by the third method was far better, 942 grams evaporating in six days, and only 610 grams in four days

December 6, 1906—"The Theory of Photographic Processes Part iii The Latent Image and its Destruction" By S. E **Sheppard** and C E. K **Mees.** Communicated by Sir William Ramsay, K C B, F R S

The authors consider that "developability" is brought about by the acceleration of reduction by preliminary treatment The essential chemical reaction in development is

$$Ag + R'' \rightleftharpoons Ag|met| + R',$$

which normally proceeds to a state of equilibrium If now to this state of equilibrium any cause tending to lower

the metastable limit of the silver solution be introduced, then the halide becomes developable. The following substances can act as germs for a dry plate:—(a) silver, introduced as colloidal silver and then converted to the metallic state, (b) gold, (c) platinum, (d) silver sulphide, (e) gas ions from flame gases.

All evidence tends to the conclusion that a necessary and sufficient condition for "developability" is the production in the silver-halide grain of a new substance. The authors have accepted a chemical theory of the latent image chiefly on account of the way in which the latent image gives certain definite chemical reactions, and especially on account of the destruction of the latent image by oxidising agents. They have made an extended investigation of the destruction of the latent image by chromic acid, with especial reference to the theory of primary and secondary development put forward by Mr. Sterry in January, 1904. This theory suggests that the primary image formed by the development of the "latent" image is intensified by silver transferred from other parts of the film.

The authors found that exposed plates, dipped in chromic acid solution before development, have their γ_∞ and inertia unaltered, but the development-velocity constant, K, lowered by the action of the chromic acid adsorbed to the silver bromide. This chromic acid was destroyed by sodium sulphite, and the plates then gave a normal K. If, however, a plate was left after chromating, before development a fall in γ_∞ was found which could not be destroyed by sulphiting, and which therefore showed an absolute destruction of the latent image. Probably this action was a re-oxidation process.

The second part dealt with a peculiar action of salts of copper, iron, mercury, and uranium, which desensitise the plate, so that enormous exposures are required to produce normal results. If the plates are exposed and developed after desensitising, K and γ_∞ are found to be normal. If, however, the plates are left for a long period after exposing, then the desensitisers destroy the latent image by lowering γ_∞ in the same way as chromic acid.

The theory advanced for this action was that desensitisers act by catalysing the oxidation reaction, which is the opposite to the ordinary light reduction action, and this view was supported by experiments which showed that with copper, quinine salts, and with iron oxalates restored the lost sensitiveness, a result analogous to that obtained for the negative catalysis of quinine in the case of the catalysis of sodium sulphite oxidation by copper salts.

The authors have also repeated the experiments of Abney and Englisch upon the failure of the Bunsen-Roscoe reciprocity law, and of the integration of intermittent exposures. The results obtained agree with those previously found. The authors consider ripening to be due to the joint action of the (a) formation of resonating systems, (b) formation of reduction product, the function of the gelatin being to form resonators and to assist in reduction.

The authors consider the formation of the latent image to be connected with the photoelectric effect, and to be due to the liberation of electrons which ionise the halide and the surrounding gas. This theory accounts for the action of dyes as sensitisers for their own region of absorption, since these electrons will ionise the halide effectually. Ionisation leads to chemical reduction, resulting in the formation of a subhalide in solid solution.

THE PLANT AS MACHINE

Plant Response as a Means of Physiological Investigation. By Prof Jagadis Chunder Bose Pp xxxviii+781, with 278 illustrations. (London: Longmans, Green and Co, 1906)

THE emotions that will be aroused by this book in different classes of readers may well be very dissimilar A biologically equipped reader with no special knowledge of plant physiology will experience dazzled admiration for the logical, progressive way in which the author builds up, not in words, but actually experiment on experiment, a complete functioning plant from three simple conceptions These conceptions, which will be critically considered later, are briefly the following —*stimulation*, the transference of external energy to the plant, *contraction*, the constant "direct response" of plant-cells to stimulation, *expansion, including growth*, the "indirect response" to stimulation

This present book, big as it is, is devoted almost entirely to the mechanical responses of plants, another volume is promised on electrical responses By mechanical responses we are to understand all movements, in the widest sense, not only the obvious movements of sensitive and sleeping plants with all geotropic and heliotropic movements, but also the movements of expansion in growth and the pumping of water up the plant, and, further, "death-spasms" and all the minute shrinkages of unspecialised cells produced by stimulation All these vital manifestations are dealt with in sequence, passing from the simple to the complex, and in them the author finds nothing that cannot be interpreted in terms of his three primary conceptions

Another type of reader, a student of plant physiology, who has some acquaintance with the main classical ideas of his subject, will feel at first extreme bewilderment as he peruses this book It proceeds so smoothly and logically, and yet it does not start from any place in the existing *corpus* of knowledge, and never attaches itself to it with any firm adherence This effect of detachment is heightened by the complete absence of precise references to the work of other investigators The student, puzzled by the number of original conceptions, may hesitate between accepting and rejecting the whole book, and will probably wait, with judgment suspended, until someone with more conventional ideas of the plant than Dr Bose has re-investigated the phenomena and interpretations here brought forward

The extreme isolation of this book is no doubt to be explained by the author's scientific past Dr Bose is, we believe, a physicist originally, and has been drawn into biology by following up the similarities which he has announced between the electrical and other responses to stimulation given by metal bars and by living animal or vegetable cells (see "Response in the Living and Non-Living," 1902) Dr Bose preaches the continuity of response in all matter, living or non-living, in metal wires, muscle fibres, sensitive plants, and vegetable cells in general, and has described effects in metals corresponding to fatigue, latent period, summation of stimuli, temperature-optima, and other characteristic vital phenomena. From this similarity of the effects of stimulation he passes to assuming a similarity of mechanism in all these cases In metal bars the mechanism is, of course, physical, and there is no question of stored chemical potential energy liberated on stimulation this purely physical interpretation is by him extended to living cells, molecular change of protoplasm, not chemical change, is all he recognises, and when a temporary storing of energy has to be admitted he considers it a purely physical accomplishment

The originality of this and of other fundamental views stated or implied in this book makes it more important for a reviewer to consider these conceptions critically than to give an outline sketch of the whole book, interesting and stimulating though it is

Dr Bose conceives the living organism as a delicate responding physical machine the responsive movements of which are brought about entirely by external stimuli All external stimuli, chemical, thermal, mechanical, photic &c, produce the same *direct response*, namely, contraction of the cells with active expulsion of water, a negative turgidity-variation, and a negative electrical variation

These effects are observable, not only in so-called "sensitive" plants, but in all living parts of plants, and it is a definite advance, due to Dr Bose's delicate experimentation, to have it shown that all radial organs, stems, styles, stamens, &c, shorten on stimulation

In addition to the direct response of contraction there is also an opposite effect, the so-called indirect response of expansion, which is produced at a distance from the stimulus by the water expelled in contraction causing distension or expansion of cells elsewhere, with accompanying positive turgidity-variation and positive electrical variation Of this nature, an indirect effect of stimulation merely, is the characteristic vital phenomenon, growth

Much, then, is made to depend upon stimulation, yet the author holds the astonishing view that all the work done by the plant is the real equivalent of energy received by the impact of stimuli from without The author does not even attempt to impart verisimilitude to this view by including food materials among his stimuli For him the living organism is not a combustion engine doing work by the energy liberated chemically in oxidising carbon compounds, but it is just such a physical machine as a windmill, requiring blows rather than food to make it work and the last picture in the book is indeed a figure of this windmill We fear that, valiant and thorough as Don Quixote in his attack upon this misconceived phenomenon, the author hardly avoids a similar fate by starting with an inverse misconception

It is easy to see that Dr Bose acquired this view of stimulation originally from his experiments on the

responses given by metal bars In these experiments the work done on the bar, generally by torsion, greatly exceeded the output of energy in the electrical and other response produced There is no liberation of stored potential energy in such a case, therefore there is really no similarity with the mechanism of the living cell, though molecular change no doubt occurs in the protoplasm as it does in the metal wire

Just as we hold that Dr Bose has transferred from his physical experiments a conception of biological stimulation which is inadmissible for either animal or vegetable cells, so it seems to us that his conception of contraction is derived only from the activity of animal muscles, and is inadmissible for the mechanical response of plant cells There is really no evidence that these two phenomena are of quite the same order and both due to active contraction of the living part of the cell, though an *a priori* philosophical outlook has led many to assume it

When the irritable stamens of Centaurea are touched they shorten, even to one-third of their length, which diminution is accompanied by an extrusion of a corresponding amount of cell sap from the cells into the intercellular spaces, and by comparative flaccidity of the cells

Now the vegetable cell, unlike the muscle cell, is at its maximum rigidity when at rest, being distended by the osmotic force of molecules dissolved in its sap These molecules are kept in by the protoplasmic lining of the cell, which is impermeable by them though freely permeable by water The tenacious and elastic cell-wall, itself freely permeable to everything, is able, owing to its tenacity to protect the protoplasm from being ruptured by the osmotic pressure, which reaches several atmospheres

Whether one holds the view that the shrinkage which occurs on stimulation has, as its antecedent stage, decomposition of some of the osmotic molecules or sudden permeability of the protoplasm, the contraction itself cannot be attributed to active contraction of the living part, but must be due to the forceful elastic contractile recovery of the dead cell-wall, now no longer distended through osmotic force It is incredible that the stimulated protoplasm, so watery in texture, can contract actively against an extending force of several atmospheres and actively expel cell-sap Unlike muscle, the "contracted" plant cell is flaccid and the protoplast does its mechanical work while recovering from contraction, in again extending its wall ready to react to fresh stimulation This corresponds to the relaxation time of a muscle, so that the two machines are quite different in their phases

Further, another fundamental difference lies in this, that a muscle does not really contract in volume when stimulated, it merely alters its shape, becoming shorter and broader, a special property exhibited by a number of non-living peculiarly organised structures, india-rubber strips, for example The plant cell, on the contrary, really contracts in volume, whether it alters its shape depends upon the relative extensibility of the different walls Again, this contractility of plant cells is inherent in the very organisation of the cell, and is found in all primitive types, and in all young cells, and is not a specially evolved mechanism like the contracting muscle fibre It is finally interesting to note that it has not been really proved that heat production is associated with the contraction of plant cells rather than with the subsequent expansion when work has to be done by the protoplast

Dr Bose's conception of growth is more elusive and still more isolated Growth, the indirect remote response to stimulation, is due to that part of the energy of a stimulus not used in direct response This energy is held to be communicated hydraulically to the growing point as pulsations, and of these pulsations graphic records are given. Stimuli applied directly to the growing region must, of course, cause contraction, *i e* retardation of growth, as their direct response, therefore the pulsations of the growing point are attributed, as indirect responses, mainly to excitatory reactions occurring below the zone of growth

Dr Bose's book abounds in experimental evidence on all points, a feature of the greatest merit, yet we must say that many of the fundamental experiments are not nearly critical enough For example, one reads continually of the striking effect of *thermal* stimuli these are produced by the electric heating of a platinum-wire-frame which surrounds the living stem, when a succession of stimuli is wanted it is produced by passing and cutting off the current alternately In relation to this treatment we are given no idea of the temperature that the wire or the plant attains, or of how far the temperature of the plant actually oscillates under this alternately hot and cold environment The effects produced in this way are very extraordinary—longitudinal contraction of stems, styles, and other radial organs, stimulation of *Mimosa* pulvini, &c —but there is no attempt to trace the transition from such effects to those of surrounding high temperatures which are kept uniform

The reader rather distrusts the author's views on thermal effects on finding him propose seriously to examine (chapter xliv) the effect upon growing parts of "thermal radiation" apart from the effect of the actual temperature of the part This distinction is surely confusion of thought, and the differences recorded are no doubt due to actual difference of temperature, for the method of experiment is quite fallacious It is, indeed, supposed that a plant surrounded with a hot radiating platinum spiral, the whole being enclosed in an experimental chamber, will be at the same temperature when there is a heat-proof screen between the plant and the radiating spiral and when this is removed, and this just because a thermometer somewhere in the general air of the chamber keeps a uniform constant temperature all the time!

The apparatus and the experimental methods employed show great ingenuity and a praiseworthy simple directness of attack which, however, occasionally passes into *naïveté* One feels that valuable results are to be got with the delicate optical lever, the kunchangraph, the balanced crescograph, the

morograph, &c., instruments which measure changes of one-hundredth of an inch or less, though their very delicacy must introduce sources of error, about which nothing is to be found in the book. Workers on growth will be forced to abandon their primitive and clumsy methods, and much good will result from the refinements here introduced

In conclusion, we can only say that there are literally scores of special points of the greatest interest raised in the course of this book, which cannot, of course, be dealt with here If the primary desire that these points raise is the desire to cross-examine, it is to cross-examine, not the author, but the plant itself which bears such uniform and honestly-intentioned testimony in favour of Dr Bose's views All such experimental cross-examination will make for the progress of knowledge, and we think that Dr Bose can claim that his book will be an external stimulus (if not in his sense at least in ours) to the growth of plant physiology and the responses of future investigators

F F BLACKMAN

THE NORSEMEN IN THE ORKNEYS

Monumenta Orcadica The Norsemen in the Orkneys and the Monuments they have left By L Dietrichson With original drawings and some chapters on St Magnus Cathedral, Kirkwall, by Johan Meyer Pp xiv+200 (Kristiania, London Williams and Norgate, 1906) Price 3l net

THIS handsome quarto volume from the pen of the learned head of the Art Museum of Christiania is issued in a bi-lingual form, being divided into two parts, the first is an abridgment in English of the second, which is in Norwegian It appears at an opportune time, when the ties connecting the two kingdoms are closer than they have ever been since the separation of the islands with which it deals from the Scandinavian kingdom on the marriage of the daughter of Christian I to the Scottish king in 1469

Based chiefly upon the importance of the Orkney Islands to Norway as a basis in the Middle Ages, and on the historical interest attaching to the architectural remains of the centuries during which they were ruled from that country, the author's task has been a scientific inquiry into every detail connected therewith He displays throughout a most intimate knowledge, not only of the Sagas, but of the writings of those authors on both sides of the German Ocean who have essayed to identify the sites and fix the questions of the dates and details of construction of the more important erections, and during a visit to the islands half a dozen years ago, when he was accompanied by Mr Myers, he had an opportunity of personal inspection of the remains, and has produced a work that will be heartily welcomed by all students of the archæology, history, and architecture of our northern isles.

The introduction deals with the Orkneys and their connection with Norway, and with the Orkneys in literature, in which the author, after enumerating all the islands and parishes with their Norse derivatives, adjusts a few of them according to his own researches, describes their scenery, climate, and natural history, and gives a list of many Norse words surviving in the names of homesteads and in the dialect, the Roman, Norse, and Scottish authors whose writings have constituted the sources of the history of the islands are also briefly referred to In order to present the work as a continuous whole, the author has included the pre- and post-Norwegian periods, and divided it into three books, dealing respectively with the prehistoric, the Norwegian, and the Scottish remains He is in full accord with all other Norse scholars in repudiating the idea of a Scandinavian origin for the sepulchral chambers, stone circles, standing stones, and brochs which abound all over the islands, these he briefly describes, without, however, committing himself to any of the various theories that have been urged regarding them, and relegates them all to a period anterior to A D. 600

From that period to A D 872 is assigned to an early Celtic Christian occupancy, that of the Peti and Papæ The distinguishing architectural features of their chapels are pointed out, six existing ruins are enumerated, while from saintly dedications and Saga records the sites of eight additional ones that have disappeared have been identified

The Norse period 872 to 1468 is the most important and interesting portion of the work, there is already a large amount of literature dealing with this period, and to those who have been nurtured on the contributions of Munch, Dryden, Anderson and others there may be much of detail to unlearn by those who accept the author's views At the same time, the older works suffer nothing by the comparison, in fact, any faithful interpretation or correlation of facts, both historical and monumental, could hardly have been looked for until after the publication of the Rolls edition of the Icelandic Sagas in 1887 Prof Dietrichson opens it with a wave of emigration from Norway to the island of Sanday where he supposes the first stronghold of the earls to have been established The monuments are chronologically arranged, the first group comprises the remains assigned by the author up to the end of the tenth century, and embraces the tumuli bearing the names of the Saga characters who are recorded as having met their death in the Orkneys and as far south as the Oykell in Sutherland the Norse burial mounds being distinguished from the Celtic "cairns" by their having been constructed, not of stones, but of earth "barrows," as well as a few churches and the Norse earls' palace as Birsay

With the eleventh century the interest increases, among the more important items which are new may be mentioned the confirmation of the opinion that the Thing-stead was held in Rendall, in opposition to the popular belief that it was at Stenness The question of the time of the erection of the unique St Magnus Church on Egilshay, which has been a puzzle to antiquaries for a long time, has been focussed for various assigned reasons into the three years immediately following the murder of the earl on that island, that is, 1135–8

Ecclesiologists who have been searching for the

missing monastery recorded by Fordun as existing in the Orkneys, and for which sites have been claimed in Helliarholm and Stromness, will be interested to know that the hitherto disregarded buildings in the immediate vicinity of the chapel on Eynhallow are recognised by the author as part and parcel of one whole establishment, which he is satisfied is none other than the Cistercian monastery presided over by Laurentius until he was transferred to Melrose in 1175

Coming to speak of the cathedral of St Magnus, "the grandest building in the Orkneys, next to Trondhjem Cathedral the mightiest monument of the whole of ancient Norway," he looks upon it as the living embodiment of the idea that when the warlike spirit of the Vikings sank to rest their intellectual strength and civilising power came into play Mr Myers contributes chapters on the architecture and the architectural history of the cathedral, also a comparison with buildings of the same period elsewhere On entering the building he is appalled by the vulgarity that dominates the whole of the modern decoration, especially the painted wooden screen, the hideous galleries, and the walled-up triforium, and appeals to the noble Scot by picture and pen to remove the disturbing additions and regain the grand effect of an unbroken interior

These chapters will be read with great interest, the more so as a recent large legacy is available for the repair and restoration of the building They are given in full in both languages characterised by strong individuality in the method of treatment, and exhibit a wider range of professional knowledge of the subject than has hitherto been displayed in its investigation, entering minutely into details of construction and ornamentation, as well as interpreting the thoughts of the various builders to whom he has assigned the different additions and alterations He introduces many ideas that will be new even to those most familiar with the building and who have given it much consideration The result of his comparison with Durham, Southwell, Dunfermline, the late lamented Selby and some others leads him to conclude that the artistic tendencies which produced the original structure issued mainly from the north of England, probably Durham, and spread not only to Orkney, but to the west of Norway. Passing on to other buildings of the Norwegian period, the author traces from the existing ruins of the bishop's palace at Kirkwall the form and subdivisions of the original structure, describes the more modern additions, and mentions several points on which his conclusions differ from those of former writers He says of the palace —

"There is no building in the Orkney Isles that is more revered by us Norwegians than the palace in which our greatest king died "

A short account of the Norse earls' palace at Birsay and Notland Castle in Westray ends the Norse period.

The Scottish division treats of the Stuarts' palaces at Birsay and Kirkwall, and of the style of building in town and country, in which Norse characteristics blend more or less with the now almost all-prevailing Scottish style

The five appendices to the volume comprise a lengthy Orkney chronology; lists of Orkney earls and bishops, the island names mentioned in the Sagas, Fordun, and other authors, down to the most recent chart in a carefully tabulated form, and a table of the genealogy of the Orkney earls The work is profusely and beautifully illustrated, chiefly by original drawings executed by Mr Myers The cover bears the arms of Kirkwall emblazoned on it. The book is one of the most valuable contributions to the historical literature of our islands, if not the most, that has appeared since the time that Barry first published his "History"

J W CURSITER

ORGANIC CHEMISTRY FOR STUDENTS

Cours de Chimie organique By Fréd. Swarts Pp 669 (Paris A Hermann, 1906)

ACCORDING to the preface, this book is intended for medical, engineering, pharmaceutical, and other students who, having attended lectures in organic chemistry, desire to increase their knowledge of the subject without expending the time necessary for a more advanced course It is founded on the author's lectures delivered to students commencing the study of organic chemistry at the University of Ghent To these lectures Prof Swarts has added, as far as possible, the descriptive material which he considers necessary for the study of elementary organic chemistry, as also the discussion of the theoretical points omitted from the lectures in consequence of lack of time The distribution of these theoretical discussions throughout the text is preferred to their collection in an introduction, as giving the student an opportunity of first becoming acquainted with the substances concerned, only the more typical of which are specially described

Such a book is admirably planned to assist the student who has had the stipulated preliminary training in realising the close connection which exists between the experimental facts and the theories of organic chemistry It is, therefore, all the more to be regretted that, after opening the introduction with a few historical remarks, the author has inserted a number of short sections on such subjects as isomerism, metamerism, polymerism, tautomerism, multiple linkings, and stereoisomerism In any case these are subjects which are bound to be referred to in the descriptive text This, in fact, happens, stereoisomerism, for example, being discussed in a far more satisfactory manner with the crotonic acids and with fumaric and maleic acid

These matters are followed in the introduction by the usual few pages devoted to an account of qualitative and quantitative elementary organic analysis It seems to the present writer that however useful such pages may be in the ordinary text-book on organic chemistry, in a book which lays special stress on the theoretical as opposed to the descriptive side

of the subject it would have been better to omit these and to have utilised the space so saved in filling up some of the gaps left in the theoretical treatment, and to which we refer later. The same remarks apply to some extent to the sections on the separation of organic compounds, which are valuable in so far as they treat of the law of partition and the distillation of mixtures of miscible and of non-miscible liquids, but much space is taken up by descriptions of working methods unnecessary to the student who has attended an experimental course in the subject, and insufficient for the instruction of the inexperienced. Again, in a book of limited space, why lavish two whole pages on illustrations of a large table carrying a small combustion furnace, with tube and fittings, and of an ordinary type of reflux apparatus! The book could hardly have suffered from the omission of these, together with most of the remaining illustrations, the instructional value of which, for example, of the sketch of the superseded distilling tube of Le Bel and Henninger, or of the large acetylene burner on p 95, is not always apparent

Having found fault so far with the introduction, and that chiefly because of its failure to reach the standard of excellence set up by the preface, we must state that the theoretical discussions throughout the remainder of the book are clear and satisfactory, as are also the later portions of the introduction dealing with the calculation of formulæ and molecular weights, the thermochemistry of carbon and the general properties and classification of the compounds of carbon according to their structure

Of the 585 pages remaining after the introduction, 317 are devoted to the consideration of the alicyclic compounds and thirty-nine to the cyclic groups intermediate between these and benzene This, with its derivatives, is described in 175 pages, leaving only fifty-four for the discussion of the heterocyclic compounds, the glucosides, the albuminous substances, and the soluble ferments As the book contains comparatively little small print and the margins are ample, it follows that some of the groups must be treated in but a scanty manner, if at all, those included under the three last headings being the chief sufferers from this cause Certainly in the space at his disposal the author gives a surprisingly comprehensive review of the more important of the heterocyclic compounds

The arrangement of the alicyclic compounds differs in several respects from that to which we are accustomed The esters appear under the old name of "compound ethers" amongst the ethereal derivatives of the alcohols, whilst we do not make acquaintance with the ketones or the aldehydes until after the description of the monocarboxylic acids and the substances derived from these A few helpful tables are given showing the principal mono- and di-basic acids with their main physical properties, and of the aldoses with the corresponding penta-hydroxy-acids The carbohydrates are followed by a succinct account of the derivatives of carbonic acid

In the course of the chapters on the alicyclic compounds, optical activity and the hypothesis of the asymmetric carbon atom, the dynamics of esterification, the nature and properties of the pseudo-acids, the constitution of the complicated derivatives of cyanogen, and the employment of the inversion of cane sugar in the measurement of the strength of acids, are clearly if briefly explained Similar concise discussions of the question of the structure of the benzene nucleus—including the arguments in favour of the centric formula, the application of Thiele's hypothesis of partial valencies, and the bearing of the optical properties—and of the constitution of the diazonium salts and the diazotates and their relation to the nitrosamines are to be found in the chapters on the aromatic compounds We must remark at the same time that there is no mention of several important matters, such as the difficulty of esterifying certain carboxylic acids by boiling with alcohol and an acid, and Victor Meyer's explanation of this on the assumption of the so-called "space interference," nor can we find any account of Gustav Komppa's synthesis of r-camphoric acid

References to the original literature are of great value in all beyond the most elementary text-books, and would have been specially so in a work intended for the use of students otherwise unguided, here such references are entirely wanting Only occasionally even does the description of a reaction, a synthesis, or a theory suggest its author's name

The book is provided with a subject index but not with a table of contents, fortunately, the page-headings are well arranged Although some portions of the book are decidedly disappointing, on the whole it can hardly fail, if conscientiously read, to broaden the views even of students considerably beyond an elementary stage of knowledge in organic chemistry

G. Y

SOME OPINIONS ON TEACHING MECHANICS

The Teaching of Elementary Mechanics Discussion which took place at Johannesburg at the British Association Meeting in South Africa on August 29, 1905, in Section A, Prof Forsyth, President of the Section, in the Chair, together with written criticisms and a paper by C E Ashford, M A Edited by John Perry Pp 74 (London Macmillan and Co, Ltd, 1906) Price 2s net

THIS little book is another addition to many outcomes of Prof Perry's never-failing activity and energy in trying to improve the teaching of our schools in matters connected with elementary science At the British Association in Johannesburg last year Prof Perry, in the midst of his arduous duties as general treasurer of the association, found time to open a discussion on the teaching of elementary mechanics, and, not content with this, he collected the remarks of all the speakers at the meeting and specially engaged a "chiel takin' notes" to keep a record of their speeches He next wrote round to a large number of teachers and others in England,

and if he only received eleven replies it cannot be denied that the writers of these replies fairly represented all sorts and conditions of men, and that the subject has been discussed, (1) in its academic aspect, (2) from the point of view of the experienced schoolmaster, and (3) from the standpoint of the engineer The book contains a reprint of the recommendations of the Committee of the Mathematical Association on the Teaching of Elementary Mechanics

What conclusions can the average reader infer from the divergent opinions expressed in this book?

(1) There is a general consensus of opinion that the teaching of mechanics should be more experimental and less dogmatic

(2) Prof Perry condemns the use of costly and complicated laboratory apparatus, and considers that more can be learnt from a cheap screw jack and a rusty old pulley than from costly Atwood's machines In this he is perfectly right

(3) If the teaching of mechanics is to be made more practical, greater attention should be paid to friction and other resistances which occur in nature So long as friction is shelved into the background, mechanics cannot be anything but the study of what would happen under impossible conditions

(4) The advocates of the poundal and the advocates of the slug will never agree

(5) The academic side does not wish the poundal adopted for practical purposes (p 13) In examination papers answers are never—well hardly ever—asked for in poundals, and generally a candidate would lose marks by giving the pull of a railway engine in poundals or tonals But the academic teacher strongly objects to swallowing the slug, and not without reason

(6) The engineering side is trying hard to force the slug down the throat of the academic teacher, its main plan of campaign consisting in attacking the poundal as unit of force

(7) Both sides seem willing, up to a certain point, to allow beginners to solve elementary problems by the use of Newton's laws, according to which change of motion is proportional—not equal to the impressed force - a method which avoids both the poundal and the slug But they still cling tenaciously to the modern substitute for Newton's statements

(8) The engineering side has had to accept the C G S dynamical units and there seems no reason why schoolboys should not leave the equation $F=ma$ until they learn to work with the metric system

(9) The universal adoption of the metric system affords the most probable direction for a compromise

(10) Prof Perry advocates (p 61) teaching mechanics through force rather than through mass as the *fundamental notion*, and yet some remarks seem rather to indicate that he wishes *every schoolboy* to realise that force is the vector time flux of momentum

(11) Many teachers condemn tonals, velos and celos, others strongly advocate them One critic (p 55) goes so far as to express regret "that for units of momentum and mass-acceleration we have no suitable names at all", but does not the *poundal* meet his requirements when regarded as the unit of *mass-acceleration?* Surely it is the use of this unit for measuring *forces* (by naval engineers and others) that is open to the serious objections raised on p 64

(12) The same differences exist in regard to centrifugal force

We have no wish to reopen controversies on these questions, but we cannot help thinking that if every schoolboy is to know the laws of motion, it is also important that every schoolboy should know a great deal about the laws of the country he lives in He should also learn something about economics, something about choice and chance, in order that he may not develop into a gambler, some experimental and geometrical optics, and many other things besides, which he does not now learn That "it must be good for all boys to learn something of measurement and how to use their hands" is a point on which all can agree with Prof Perry G H B

OUR BOOK SHELF

What Are We? By Leonard Joseph Pp xiii+394 (London Kegan Paul, Trench, Trübner and Co., Ltd, 1906) Price 15s net

"THEY say the owl was a baker's daughter Lord, we know what we are, but know not what we may be" A certain incoherence in Ophelia's words would have prevented us at one time from regarding her as a possible authority on the metaphysical questions raised by the title to this book, but she is soundness, suggestiveness, and lucidity themselves when compared with Mr Joseph

Three peculiarities in this pretentious work will strike the observant reader —(1) Excellent as "Chambers's Encyclopædia" and the paper called *Answers* are in their own place—and Prof York Powell is said to have thought highly of the latter—we doubt if there are many scientific works of the first rank in this country in which these are paraded in the foot-notes or in the list of books consulted (2) Mr Joseph poses in the opening paragraphs as an orthodox believer whose motto is "Search the Scriptures, watch and pray," but confesses in the end, with much pride, that this is merely a device to secure for his pages a reading from unreasonable and stubborn church-goers It would have been more tactful to assume that all his readers were reasonable human beings, or that, at any rate, the weight of the arguments adduced would of itself overcome all initial distrust (3) Mr Joseph argues soberly—if the term sober can be applied without contempt to one who apparently abhors total abstainers as amongst the most depraved of men—for sexual promiscuity This is bad, indeed, it is even worse than the unsound physiology that defaces the last page, or than the wealth of padding which surrounds and encompasses what might have received adequate treatment in a sixpenny pamphlet

The Human Mechanism, its Physiology and Hygiene and the Sanitation of its Surroundings By Prof. Theodore Hough and Prof W T Sedgwick Pp ix+564 (Boston and London Ginn and Co, 1906) Price 8s 6d

MANY writers of text-books on physiology for the lay public are quite incompetent to act as teachers of their fellow men, because they are unacquainted with the

science they profess to write about, or imagine that a description of the bones and a few other anatomical facts constitutes physiology so far as the general public are concerned. There are, of course, some books which are notable exceptions to this rule, but we never remember to have seen one before which so admirably fits the purpose for which it is written as the little treatise before us, which the authors have labelled "The Human Mechanism."

A little anatomy has, of course, to be introduced, but this is kept in the background; what comes to the front is the study of function; this is well up to date, and the first half of the book is a clear and succinct account of modern physiological knowledge. It avoids unnecessary details, but omits nothing essential. It is so lucidly written that the wayfaring man will have to be a terrible fool if he does not understand it.

From such a sure bed rock, the authors pass on in the second part of the book to the application of physiological laws, and treat of personal, domestic, and public hygiene in turn. We can award to this part no higher praise than to say that it is as excellent as the preliminary physiological portion. It teems with sound practical common sense; it points out convincingly, avoiding too great technicality, the scientific reason for their faith. If the people at large and their rulers could be induced to act on its precepts preventive medicine would indeed make a great stride in the battle man is always waging against disease and the consequences of his misdeeds.

Arithmétique graphique. Introduction à l'Étude des Fonctions arithmétiques. By G. Arnoux. Pp. xx+226. (Paris: Gauthier-Villars, 1906.) Price 7.50 francs.

Assisted by M. Laisant, the author has put into an interesting and occasionally novel form the elementary theory of congruences, indices, and residues of powers. He has also given various examples of the use of Galois's imaginary units, and of the solution of cubic congruences by means of Cardan's formula. There is nothing essentially new in the book, but it is entertaining as the work of an amateur who has looked at the subject in an independent way, and has occasionally put the facts into an unusually vivid form, for instance, when he gives a chess-board diagram showing the solutions of $x^2+y^2 \equiv 2$ (mod 5), and so on.

Familiar Trees. By Prof. G. S. Boulger. Pp. vi+160. (London: Cassell and Company, Ltd., n.d.) Price 6s.

As the author informs us in his preface, the book is an endeavour to describe the beauties of our familiar trees. He further points out that "Their many associations have interests that appeal to the historian and the moralist, to the student of literature and of folk-lore, but little less than to those interested in botany." . . . "The time has gone by when we could be content to stand agape at the wonders and beauties of the world of Nature; we require now some attempt, at least, at an analysis of the origin, purpose and significance of the objects of our admiration." Mr. Boulger has certainly given a fairly interesting account of a few of the commoner trees and shrubs. In his introduction he defines trees as perennial plants with a principal stem of some considerable diameter, rising from the ground and forming wood. Their woodiness distinguishes them from all herbs, and their one principal stem from shrubs. In spite of this, however, he includes in his book of familiar trees shrubs and even climbers, while such familiar trees as the oak, beech, and the lime are omitted and the Scots pine dismissed with a passing reference.

The author has, however, brought together a considerable amount of interesting material concerning the species with which he deals, and the value of the book is greatly enhanced by the many beautiful coloured plates and photographs. The appearance of the cross-section of the wood of the various species is well illustrated by selections from Mr. J. A. Weale's unique collection, and these, like the other plates and figures, do great credit to the artists by whom they were produced.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Radium and Geology.

After reading Arrhenius's vivid account[1] of the bombardment of the earth by electrically charged solar dust, one is prepared to appreciate Prof. Joly's hypothesis as set forth in his letter in NATURE of January 24. On the other hand, Mr. Strutt's analysis of granite affords strong support to the view that the radium it contains is of terrestrial origin. The concentration of this constituent in the biotite might conceivably be due to the absorption of percolating water containing radium in solution, but not in the zircon, a mineral which is as impermeable as quartz. A mineral analysis of Cornish granite from Penrhyn made by Miss Davies in our geological laboratory gave the following results:—orthoclase, 24.62 per cent.; albite, 13.42 per cent.; quartz, 40.23 per cent.; muscovite, 10.05 per cent.; biotite, 11.46 per cent.; magnetite and zircon, 0.16 per cent. The heavy portion of the Cornish granite analysed by Mr. Strutt which was insoluble in hydrochloric acid, consisted of silica hydrate and zircon, and if the latter mineral was present to the extent of 0.16 per cent. only, it must have contained, judging from the analysis, 0.637×10^{-12} gram of radium per gram, or a little less than was found in crystals of zircon from North Carolina. In the consolidation of granite the zircon crystallises out first, then the biotite, next the muscovite, afterwards the albite, and finally the orthoclase and quartz; but the concentration of radium diminishes in a similar order, a correspondence that can hardly be the effect of chance.

In the formation of granite, water has undoubtedly played a large part, and may have had a good deal to do with its differentiation from the parent magma. Water forms one of the constituents of biotite, sometimes to the extent of 10 per cent. Thus it is possible that the richness of granite in radium is due to the removal of this constituent in solution from the general mass of a magma and its concentration in certain portions which were converted by hydration into granite.

But if this be true of granite, may it not be true as well of basalt and other basic rocks in which also water plays its part, though to a less extent? All the igneous rocks to which we have access are very superficial parts of the earth's crust, and it is unsafe to reason from them to the deeper underlying regions. There may be other causes, apart from solution, by which electrically charged atoms like those of disintegrating radium have found their way up from below to enrich the outermost layers of our planet. In any case, the assumption that radium is uniformly distributed through a crust forty-seven miles in thickness seems to require support from independent evidence, and until that is forthcoming it is equally open to us to assume a thick crust, 800 miles, consisting of silicates with radium distributed through it according to some unknown law, but with a rapid increase towards the zone affected by highly heated waters.

1 Arrhenius, "Lehrbuch der kosmischen Physik," 1903, p. 149 (Leipzig.)

The Mathematical Tripos.

In NATURE of January 17 (p 273) there is a long article by Prof Perry which contains a one-sided account of the new regulations for the mathematical tripos So far as I can see, no new arguments are suggested, for every statement has been already fully discussed and as, I believe, thoroughly answered To repeat all these at length would take too much space and time, but perhaps the Editor of NATURE will allow me to remark on two or three assertions which can be answered in a few words

Prof Perry speaks of those who vote "non-placet" as the opponents of reform, yet these "non placets" have continually urged the necessity of reform It is only this particular reform that they object to It was proposed in the Senate House (*Reporter*, p 325) to have joint meetings of the two parties and to agree on some common action It has also been suggested that we might use the Smith's prizes to separate the different kinds of students It is, therefore, *the "placets' whom we ought to designate as the opponents of reform* when they refuse even to consider such proposals So also in the circular (December, 1906) issued by our committee, we say that in the event of the regulations being rejected, we are ready to cooperate in promoting such measures as would, while preserving the best features of the present system, at the same time remedy its admitted defects

In another place Prof Perry tells us that one of the most important regulations is that a student may take part i in his second term He gives no explanation why this regulation has been objected to yet this makes all the difference If students can pass part I in first-class honours in their second term, the subjects cannot be much more than schoolboy knowledge, and do not deserve Cambridge first-class mathematical honours These subjects are fewer in number than those of the existing part i Others have been curtailed for example, the *uses* of the binomial, exponential, and logarithmic theorems, and also those of Taylor and Maclaurin are required, but *without their proofs* Is a tripos *which does not include these proofs worthy of first-class university honours in mathematics?* It is a new thing that a mathematician should learn theorems *by rote* without understanding the reasons

In regard to the higher studies, there is only space to notice that the existing part ii has been generally regarded as a complete failure, yet its theory and practice are to be retained in the new programme

The proposed scheme was signed by fifteen only out of the twenty-five members of the Mathematical Board, the remainder not voting Among *college lecturers in mathematics*, our count makes the majority opposed to the scheme, and the same is true of *resident graduates* in *mathematical honours* Almost all the training for part i is now done by the lecturers and teachers in the various colleges It is only with these that the mathematical undergraduate is brought into close contact, and it is to them rather than to the professors (who necessarily confine their lectures to the highest subjects) that we should look for guidance on the needs of their pupils (see the "non placet" circular)

The name of a distinguished mathematician is claimed as a supporter by Prof Perry The name of Lord Kelvin here comes naturally to our remembrance, as he is our greatest natural philosopher If the mention of the first name is an argument, how much more that of Kelvin? Yet Lord Kelvin is opposed to the new "so-called" reformation His opinion of the university training has been given to us in his fly-sheet Other old members have also explained the good they derived from their "old-fashioned" Cambridge course

Prof Perry states that if the "non-placets" should succeed in reversing the decision of the Senate, they are establishing a precedent which cannot conduce to the smooth working of the University He must have forgotten the precedent set in 1872–3 when a proposal making Greek non-compulsory in the *previous* was carried in 1872, only to be rejected when it came up again a few months later in 1873 No constitutional difficulties appear to have followed It was proposed in the Senate House by one at least of the supporters of the scheme that if the October decision is reversed they should *repeat the voting term after term* until the opposite side was wearied out Is it considered that such a course will conduce to the smooth working of the University? So strange a plan appears to be void of all argument, and if even partially adopted will throw the whole Senate into confusion.

There are many points in Prof Perry's summary of the regulations which would require an answer if they had not already been so fully replied to. I hope I have shown that some of his statements, at least, require verification

EDWARD J. ROUTH.

Fertilisation of Flowers by Insects.

DR ALFRED RUSSEL WALLACE, in an article entitled Creation by Law," contributed to the *Quarterly Journal of Science* in October, 1867, alluded to a Madagascar orchis (*Angraecum sesquipedale*) with a nectary varying in length from 10 inches to 14 inches, and prophesied that a hawk-moth will be discovered with a tongue of equal length to fertilise it "That such a moth exists in Madagascar may be safely predicted, and naturalists who visit that island should search for it with as much confidence as astronomers searched for the planet Neptune—and they will be equally successful!" Will someone kindly tell me if this prophecy was fulfilled; if so, when, and the name of the moth?

E W SWANTON

Dr Jonathan Hutchinson's Educational Museum, Haslemere, Surrey, January 17

In reply to Mr Swanton's letter, I have not heard of any moth from Madagascar with an exceptionally long proboscis I think, however I did hear of one from East Africa with a proboscis nearly the length required, but as entomologists do not usually open out and measure the length of proboscis of all the large Sphingidæ they receive some of the required length may exist unnoticed in our public or private collections An inquiry at the insect departments of the Natural History Museum and also of that of the Jardin des Plantes would perhaps afford Mr Swanton the required information

ALFRED R WALLACE

The Immortality of the Protozoa

In a footnote to p 42 of Coleridge's "Biographia Literaria" (Bohn's Library) occurs the following statement —

"There is a sort of minim immortal among the *animalcula infusoria* which has not naturally either birth or death absolute beginning or absolute end for at a certain period a small point appears on its back, which deepens or lengthens until the creature divides in two, and the same process is repeated in each of the halves now become integral"

As I understand (for I am no biologist myself), the theory of the immortality of the protozoa was, according to the generally accepted view, first definitely formulated by Weismann in his lecture "Ueber die Dauer des Lebens" in 1881 It had been indicated before, but never definitely stated But an examination of the passage quoted above with the context in which it occurs (which is too long to be inserted here), shows that already in 1815 Coleridge could allude to this conception as one the truth of which was already accepted among biologists For Coleridge is not stating the fact for its own sake he introduces it merely as an illustration of a fact of etymology Moreover, it is not merely to the phenomenon of multiplication by fission that he alludes, but to the conception to which (at some period subsequent to its discovery) it gave birth

Coleridge took a keen interest in biology, and was, no doubt widely read in biological literature It is possible indeed, that his statement is based, not on anything that he had read, but on what he had heard in conversation with men of science of his day It would be interesting however, to know if the conception had been definitely put forward in writing at this time, and I should be much obliged if you would give me through the medium of your columns, an opportunity of clearing the question up

Perception of Relief by Monocular Vision

A STRIKING example showing how any large lens can "see" in relief (see NATURE, January 3, p. 224) may be demonstrated to an audience

An electric glow-lamp is lit in an optical lantern, and the image of the filament projected on to a screen This image is only sharp in parts

A card with a small hole in it (1/8 inch) is now placed close in front of the lens, this sharpens the image on the screen.

The card should now be moved backwards and forwards, the image *changes* in a remarkable way with every movement, showing that the lens sees the filament from a different point of view from each point of its surface

Photographs taken with the "stop" at either side of the lens make a good stereoscopic pair.

A E. SMITH

8 Farringdon Avenue, E C, January 19

THE RUWENZORI BOUNDARY DISPUTE

THE dispute which has arisen as to the ownership of the Ruwenzori Mountains between the British and the Congo State Governments is the latest example of the danger of a fixed and definite boundary agreement based on unfixed and most indefinite geographical data So long as an elementary knowledge of geography—especially of the conditions and methods which govern geographical map making—forms no part of the educational equipment of our political staff we shall have these unscientific and clumsy disputes which may easily cost the country as much as a small war

In this instance the agreement indicated, as the boundary between the Congo State and Uganda, "a frontier following the 30th meridian east of Greenwich up to its intersection by the watershed between the Nile and the Congo, &c" Presumably some sort of a map was consulted, but in 1894, when that agreement was drawn up no map could have existed which could claim to be more than approximately accurate in respect to any position fixed relatively to the meridian of Greenwich, and in the absence of detailed topography it must have been impossible to foretell whether the demarcation of such a line was even practicable For a political boundary to be of any value it must either be carried by some well-marked natural feature or pass through country where artificial demarcation is possible Consequently, of all dangerous boundary definitions that which involves a straight line through unmapped regions is perhaps the most unsafe It might be urged that in the absence of all topography it was necessary *faute de mieux* to make use of an hypothetical line In that case, treating all existing maps as a blank (which would have been the safest course), it was only necessary to express a doubt as to the finality of the arrangement whilst drafting the agreement.

In the present instance probably no one will be much the worse for an unscientific boundary muddle A certain nervous anxiety to avoid international complications has led to our hasty abandonment of a strip of country which lies between what is now determined as the thirtieth meridian east of Greenwich and that line which was supposed to represent it when the agreement was made The strip is about twenty-five miles in width, and the Congo officials have already taken possession and forbidden the entry of any white men unless engaged on scientific investigation It may be a valuable strip for rubber production or it may not. Whatever it is, it has practically been given away (like many another more important field of international frontier dispute) for the want of a little scientific knowledge of the limitations of geographical definition.

THE ART OF THE LAPIDARY.[1]

BOOKS dealing with precious stones which have made their appearance in the past may be divided into three classes First, works of exact science written by competent mineralogists, like the well-known treatises of Church, Max Bauer, and Kunz, secondly, treatises of an antiquarian character, of which the well-known works of C. W King are the most conspicuous examples, and thirdly, books written from the commercial standpoint, like those of Messrs. Streeter and Emmanuel All these classes of books treat, it is true, more or less incidentally of the lapidary's art, but the information on the subject is often second-hand and sometimes not very trustworthy

It may be readily understood that a skilful lapidary, who is constantly handling different gems from the most varied localities, must acquire an eye- and hand-knowledge of the objects of his craft of a very special kind, and the opinions of such men, based as they are on the results of constant observation and experience, may often be worthy of the attention of men of science A book written by a practical lapidary may thus be expected to have a peculiar interest of its own—one of a totally different character from that which attaches to the kinds which we have enumerated above, and thus it comes about that the work before us constitutes almost a new departure in the literature of precious stones

FIG. 1—Diamond Cleaving From 'The Gem Cutter's Craft

It is only fair to the author to point out that—while justly insisting on the importance and value of the practical knowledge of gems gained by constantly handling them and by noticing their

[1] "The Gem Cutter's Craft" By Leopold Claremont Pp xv+296 (London George Bell and Sons, 1906.) Price 15s net

behaviour on the lapidary's wheel—he fully recognises the great importance of the exact and quantitative methods of the mineralogist. The chapters dealing with the scientific methods for identification of precious stones are, on the whole, fairly complete and accurate, though evidently the information is to a great extent second-hand and sometimes wanting in precision. We notice that the suggestion of the cadmium borotungstate as furnishing a dense liquid for the separation of gems is ascribed to Prof. Church, and not to W. Klein, while the recommendation of the use of the mixed silver and thallium nitrates is accompanied by no hint of the limitations to the use of this substance imposed by its high price and tendency to change colour. The Abbe refractometer is described as a means of determining refractive indices, with no suggestion as to the existence of simpler and cheaper instruments, like those of Prof. Bertrand and Mr. Herbert Smith. The use of the Röntgen rays in differentiating between the various gems and paste is described, but no reference is made to the valuable and exact observations published by Prof. Doelter on this subject. In the same way antiquarian subjects, like the classical and biblical names applied to gems, are dealt with in a very perfunctory manner, the uninstructed reader being left in ignorance as to the wide differences of opinion which exist as to the identification of the particular substances referred to by ancient authors.

It is when the author comes to deal with the practical work of gem-cutting that we feel that he is on safer ground, and his account of the method of cutting and polishing both diamonds and the softer precious stones, fully illustrated as it is, has all the completeness which we might expect from one practically engaged in the industry.

The ordinary methods of "soldering" diamonds into cones of metal (consisting of two portions of lead to one of tin), and grinding and polishing facets by pressing them against a rapidly revolving wheel armed with diamond dust, are well known. Perhaps less familiar to most persons is the series of operations—known as "slitting," "cleaving," and "bruting"—by which diamonds are made to assume approximately the required shape, before the formation of the series of facets by means of the polishing wheel ("skeif"). Diamonds are sometimes sawn across by means of the ordinary lapidary's wheel, a thin iron disc the edge of which is armed with diamond dust, but on account of the equal hardness of the dust and the stone the work is very slow and laborious. Much more frequently the form of the gem is modified by "cleaving," advantage being skilfully taken of the natural octahedral parting-planes of the diamond. The method adopted is that familiar to mineralogists, and is illustrated in the accompanying diagram, Fig. 1.

"The diamond to be cleaved is cemented upon the end of a wooden stick or holder in such a position that the plane of cleavage to be used in the operation lies parallel to the length of the stick, which is firmly fixed into the centre of a weight projecting from the wooden bench in front of the operator. A steel blade is held against the diamond in the desired position and by means of a smart blow upon the back of it, the stone is caused to divide along the cleavage plane."

FIG. 2.—Diamond Bruting. From 'The Gem Cutter's Craft.'

The process called "bruting" demands equal delicacy and firmness of hand, aided by a skill which can only be attained by long practice.

"The bruting of diamonds consists of rubbing two diamonds together in such a way that by continual friction each can be made to assume the required shape. Each diamond is cemented upon the end of a stick or holder about a foot long, and the operator firmly holds one end of each stick in either hand. The stones are then rubbed and pressed one against another over a wooden trough containing a very fine metal sieve, into which fall the particles of diamond dust rubbed from the stones. In order to obtain sufficient leverage the holders which support the diamonds are held against little metal projections on either side of the trough." (Fig. 2.)

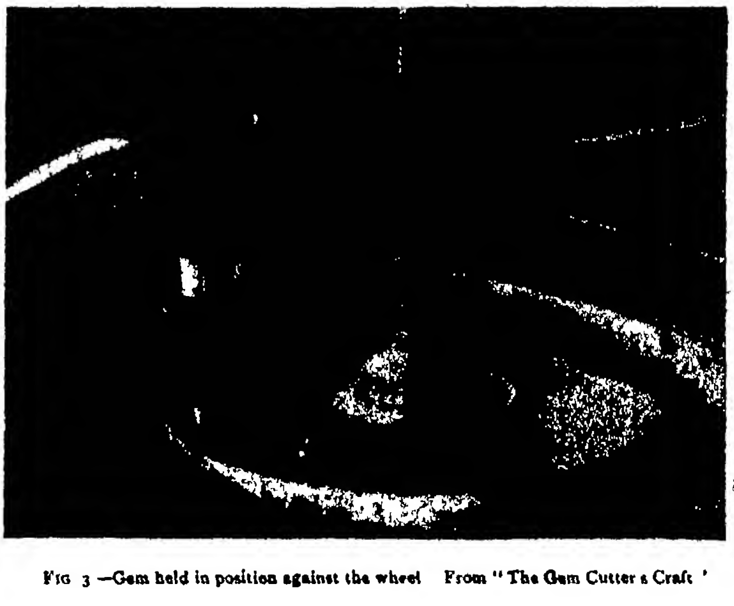

FIG. 3.—Gem held in position against the wheel. From "The Gem Cutter's Craft."

In reading the work before us the mineralogist recognises the fact that a skilled lapidary with powers of acute observation may detect phenomena that could scarcely reveal themselves in any other circumstances. Among these may be noticed the statement

that diamonds that have been cut by the lapidary's wheel lack some of the brilliancy found in gems that have been simply cleaved It appears, too, that the diamonds of different districts differ to a very marked extent in their degree of hardness; the diamonds of New South Wales, indeed, are so much harder than those from other districts that they can only be cut and polished with their own powder

Rubies, sapphires, emeralds, and other coloured stones are of less hardness than diamonds, and their cutting and polishing can be effected by means of diamond dust, carborundum, corundum, or emery But in the case of these softer gems great delicacy of touch, rather heavy pressure and friction are required for their successful facetting The gems to be polished are cemented on the end of a holder made of hard wood about the size of a short penholder, and are cut and polished by being held against metal discs ("laps") supplied with the abrasive and polishing powders (Fig 3)

The latter portion of the book, which deals with the nature, localities, and treatment of the various kinds of gem-stones, presents few features of interest as compared with other works of the kind On some points, as, for example, in the remarks on the artificial production of precious stones the information given is neither very complete nor very exact, but even in this part of the work there are occasional observations which are of considerable interest to the mineralogist

J W J

NOTES

At the moment of going to press we learn with the deepest regret of the sudden death of Sir Michael Foster

The fourteenth International Congress for Hygiene and Demography will be held at Berlin on September 23–29 All papers and particulars referring to the congress may be obtained from the general secretary, Berlin 9 W Eichhornstr 9

Herr F I Beyer, the founder of the world famed colour factory at Chemnitz fifty years ago, died at San Remo on January 2 at the age of eighty-two years The direction of the factory has for some time now been in the hands of his son-in-law, Herr Th Korner

The organisations committee of the sixth International Congress held at Rome finds itself with a balance of about 20,000 francs This sum of money it is proposed to divide into honoraria of 1000 francs each, to be given to young Italian chemists to enable them to be present at the next International congress, to be held in London in 1909

A Reuter message from Brussels reports that at a meeting held on January 29 at the residence of M Beernaert, Minister of State, it was decided in principle to organise a new Belgian South Polar Expedition A scientific committee will determine the programme The meeting appeared to be in favour of the scheme of oceanographic research submitted to the Mons Congress by M Arctowski

At the recent annual meeting of the Royal Microscopical Society, the following officers were elected for the ensuing year —President, Lord Avebury, vice-presidents, Mr Conrad Beck, Mr A N Disney, Dr J W H Eyre Dr Dukinfield H Scott, treasurer, Mr Wynne E Baxter, secretaries, Rev Dr W H Dallinger and Dr R G Hebb

At the annual meeting of the Entomological Society on January 23 it was announced that the following officers had been elected for the session 1907–8 —President, Mr C O Waterhouse, treasurer, Mr A H Jones, secretaries, Mr H Rowland-Brown and Commander J J Walker, R N The outgoing president, Mr F Merrifield delivered an address in which he discussed some of the causes of the persistent abundance or scarcity, generally or locally, of species and varieties of insects, and the relative importance of the consumption of their food and the attacks of their enemies Reference was made to striking characters that seem of no biological importance, to habits and activities not directly concerned with nutrition or reproduction, and the manner in which they are affected by external conditions and to structure and fixed habits indicating their ancestral history and affecting their present capabilities

Prof M I Konowaloff, professor of chemistry in, and at one time director of, the Polytechnikum in Kiev, died in his forty-ninth year as the result of an accident on December 24, 1906 After passing through the physico-mathematical faculty of the Moscow University he became first an assistant and then a docent of chemistry in the same university, in 1896 he was appointed professor of inorganic chemistry at the Petrowskoje-Rasumowskoje Agricultural Academy near Moscow leaving there in 1899 for the new polytechnic at Kiev in the building and equipment of which he had taken an active interest In 1902 he was elected director, but owing to a number of unpleasantnesses having arisen he resigned in 1904 His most important scientific investigations dealt with the composition of the Caucasian petroleums, the nitration of various organic compounds, preparations of aldehydes and ketones, syntheses of aluminium haloids and their isomers, refractivity of nitrogenous organic compounds, nitrogen compounds of the terpene group and the methane series &c, the similarity between the iron salts of organic acids and the nitro compounds In addition to having displayed great scientific activity Prof Konowaloff was always a strong advocate of public lectures especially for the working classes

An Association for the Promotion of Flight is in course of formation The association will aim at assisting inventors and investigators to carry out experiments in artificial flight In order to secure that no funds shall be subscribed by speculators with any hope of return, it is proposed that in the case of its ultimate success in its object, the valuable assets such as a facility for constructing practicable flight machines, should be handed, free of cost, to the nation A provisional committee has been appointed, which includes the Hon C A Parsons, F R S, Sir William Crookes, F R S Major B F S Baden-Powell, and others Major Baden-Powell who is the president of the Aeronautical Society, in a letter to the *Times* explains how the new association differs from the Aeronautical Society and the Aero Club He points out that the newly-formed association has for its main object the acquisition of a fund to be devoted to the purpose already explained The intention is to make a public appeal, and it has been considered that this could be done better by an independent body than by the existing society It is, however, clearly understood that the association shall work in entire accord, not only with the Aeronautical Society, but also with the Aero Club

The birds of Irene near Pretoria, by Mr I E Taylor illustrated by a plate of the eggs and nest of the black duck, and notes on a collection from N E Rhodesia by Messrs W E Stoehr and W L Sclater form the sub

ject of the two chief original articles in the Journal of the South African Ornithologists' Union for December last.

In the fourth volume (pp 173–192) of *Marine Investigations, South Africa*, Dr W. G Ridewood describes a new species of the hemichordate genus Cephalodiscus, obtained from a considerable depth in the Cape seas The new form brings up the number of known species to seven

The report of the Felsted School Scientific Society for 1906 is illustrated with reproductions of photographs taken by the members of that body The most interesting of these represents a nest, with eggs, of a moorhen, built, on some sticks in the river Pett, about 3 feet from the bank, with the base of the structure touching the water The society appears to be in a thriving condition

The Hon Walter Rothschild has just presented to the British Museum (Natural History) a fine mounted specimen of a male Alaskan elk, or moose (*Alces machlis gigas*), which has been temporarily placed in the central hall behind the African elephant The Alaskan elk, we may remind our readers is the largest representative of its species, although some of the estimates of its height are almost certainly exaggerated

We have received the report of the museum committee for the County Borough of Warrington for the past year It appears that Warrington was the first town in the United Kingdom to establish (in 1848) a rate supported public library and a tablet with an inscription to that effect has recently been placed in the building The excavation of the site of the Roman station at Wilderspool has, for the present, been brought to a conclusion and the spoils are in process of being arranged for exhibition

The fourth part of vol iii of the Transactions of the Hull Scientific and Field Naturalists' Club contains a coloured plate of the four known British laid eggs of Pallas's sand-grouse These constitute two complete clutches, both taken on the high wolds near Beverley in 1888, one on June 15 and the other on July 5 The only other known instance of this species breeding in the British Isles rests on the evidence of a young bird found in Morayshire The eggs are the property of Mr I Audas

Under the title of "Nature Names in America," Mr. Spencer Trotter, in the January number of the *Popular Science Monthly*, gives some interesting information with regard to the origin of the vernacular designations of many of the animals and plants of the United States Raccoon, opossum, skunk, chipmunk, and moose are, it appears, taken direct from the Algonquin language Miss I P Bush contributes a translation of a valuable article by Mr Anton Handlirsch, of the Vienna Museum, on fossil insects and the development of the class Insecta

Many naturalists will remember that after the fresh-water jelly-fish Limnocodium was discovered in 1880 and its little polyp stage also described, a very similar polyp, the *Microhydra ryderi*, was found in a back-water of the Delaware River, near Philadelphia, in the United States In 1897 the veteran naturalist Mr Edward Potts, of Philadelphia, described in the *American Naturalist*, without illustrative figures, the production of a medusa or jelly-fish by this little Microhydra The observation escaped the notice of most zoologists, and it is therefore a matter of congratulation that Prof Ray Lankester has obtained from Mr Potts a full description of the budding of Microhydra and of the medusa produced by it, accompanied by numerous excellent drawings These are published in the December (1906) number of the *Quarterly Journal of Microscopical Science* Figures are given for comparison of the medusa and polyp (Limnocodium) from Regent's Park (1880), and of the medusa of Lake Tanganyika (Limnocnida) described in 1893. Mr Potts sent a preserved specimen of the North American fresh-water medusa to Prof Lankester, who submitted it for examination to Mr. E T Browne, well known as a specialist on the medusæ, and a report and figures by him are published together with Mr Potts's memoir. The medusa of Microhydra differs greatly from that of Limnocodium, although the polyp form has many curious points of resemblance in the two genera Only very young liberated medusæ of Microhydra have, as yet, been observed There is obviously an opportunity for further study of a very interesting kind in regard to this last discovery made by Mr Edward Potts, so well known to zoologists by his researches on fresh-water sponges

The methods of preparing an accurate survey of the plants growing in a plot of pasture or meadow-land is the subject of a small brochure by the Rev E A Woodruffe-Peacock published as No 9 of the Rural Science Series The system here explained in detail is recommended to the consideration of students taking up floral analysis from a biometric standpoint

Selecting as his subject the financial success of forest management, Dr W Schlich, F R S, delivered a lecture before the students of the Royal Agricultural College, Cirencester, that is published in the December (1906) number of the *Agricultural Students' Gazette* While the lecture contains no new facts, it provides an excellent summary of guiding principles, and as a practical illustration Dr Schlich quotes from the working plan drawn up by him for the Alice Holt crown forests in Hampshire

A question that must frequently occur to fruit-growers is concerned with the causes that control the time of flowering of trees An attempt to calculate in a general way the number of heat units received in different years is discussed by Mr F P Sandsten in Bulletin No. 137 issued from the agricultural experiment station of the University of Wisconsin As would be expected, conditions during the previous summer and autumn are no less potent than temperatures in the spring, while less important factors are connected with the condition of the soil and the characteristics or state of health of each individual plant The author mentions that the number of units required to bring a tree to flower varies from year to year, but does not state whether the proportion of heat units required by different varieties remains constant, although it would appear that data suitable for deciding this point were collected

The Engineering Standards Committee has issued tables of British standard Whitworth screw threads, of British standard fine screw threads, and of British standard pipe threads The tables can be obtained, post free, for a penny, from the offices of the committee, 28 Victoria Street, Westminster

In the discussion on Mr H Campbell's paper on suction engines and gas plants, read before the Institution of Engineers and Shipbuilders in Scotland (Transactions, vol I, part iii), Mr F J Rowan gave a bibliography of the subject, bearing witness to the enormous amount of investigation and research that has been carried out during the past two or three years

INVESTIGATIONS have shown that the yellow crystalline substance deposited from solutions of ammonium molybdate has the composition H_2MoO_4,H_2O. It was noticed as early as 1876, identified in 1882, and a crystal measurement made in 1903. The properties of this interesting chemical curiosity form the subject of a paper by Mr. J. H. Graham in the Journal of the Franklin Institute (vol. clxiii., No. 1).

IN the *Engineer* of January 25 plans are given of the handsome and commodious new headquarters of the great American engineering societies in New York provided by the liberality of Mr. Andrew Carnegie. The two top floors are devoted to the libraries of the several societies, and it is intended so to administer the library of each that by bringing them together there may be created an extremely complete and valuable library of engineering science and practice.

STRIKING evidence of Japan's native industrial capacities is afforded by an admirably illustrated description, by Mr. O. G. Bennett, of Sumitomo Bessi, the great copper mine of Japan, in the *Engineering Magazine* (vol. xxxii., No. 4). Copper mining has been carried out for centuries at this peak of sulphide copper ore near the centre of the island of Shikoku. At the present time, 9000 tons of ore are raised daily by plant modern in all engineering details, the transformation from the primitive methods having been wrought without the direct assistance of a single foreign engineer.

THE presidential address delivered by Mr. F. W. Taylor, of Philadelphia, to the American Society of Mechanical Engineers is summarised in the *Engineer* and in *Engineering* of January 11. The author, one of the inventors of the modern high-speed steels, has written an address on the art of cutting metals that deserves to become one of the engineer's classics. It is probably, both on account of its length and on account of the matter it contains, one of the most remarkable that has ever been offered to a learned society. It contains the main results of twenty-six years' study of the question of obtaining the maximum output from machine tools. As the best high-speed tool steel the author recommends a steel of the following composition:—vanadium, 0.32 per cent. to 0.29 per cent.; chromium, 5.95 per cent. to 5.45 per cent.; manganese, 0.07 per cent. to 0.11 per cent.; tungsten, 17.81 per cent. to 18.19 per cent.; carbon, 0.682 per cent. to 0.674 per cent.; and silicon, 0.049 per cent. to 0.043 per cent. He has succeeded in establishing formulæ sufficiently trustworthy for the production of slide-rules by means of which it is possible to determine in a few minutes the best speed and feed to use in executing any given piece of work in any given lathe, and with any given set of tools.

IN one of the very valuable Bulletins (No. 275, Washington, 1906) recently issued by the United States Geological Survey, Mr. T. Nelson Dale describes the slate deposits and slate industry of the United States. It covers 154 pages, with twenty-five plates and fifteen illustrations in the text, and deals with the origin, composition, and structure of slate in general, and the slate deposits of the United States in particular. A full bibliography of slate and a glossary of geological and slate-quarrying terms are appended. The classification of slates adopted by the author is as follows:—I., aqueous sedimentary. A, clay slates, B, mica slates; (1) fading: (a) carbonaceous or graphitic, (b) chloritic, (c) hæmatitic and chloritic; (2) unfading: (a) graphitic, (b) hæmatitic, (c) chloritic, (d) hæmatitic and chloritic. II., igneous. A, ash slates, B, dyke slates. The scientific basis for these subdivisions is explained, and the microscopic and chemical analyses of typical slates are given. The Old Bangor quarry, Northampton County, Pennsylvania, is the largest slate quarry in the United States. The deposit measures 1000 feet along the strike, 500 feet across it, and 300 feet in depth. The general structure is a close, overturned synclinal crossed by almost horizontal cleavage. The thickest bed of good slate is 9 feet thick. The product from the large beds is used for roofing, but that from the ribboned beds goes into mill stock. The value of the United States slate production in 1904 was 1,103,439l.

Old Bangor Slate Quarry, Bangor, Pa., S.S.W. End showing the eroded overturned close syncline crossed by almost horizontal cleavage.

A PAPER on internal-combustion engines for marine purposes, by Mr. J. T. Milton, was read at the Institution of Civil Engineers on January 22. The economy and the increasing use of internal combustion engines on land has led to considerable interest being taken in their application to marine purposes, and already a large number of such engines have been fitted in small craft on the Continent, in most of which heavy mineral oil is the fuel used. On land, various fuels are used for these engines, namely, petrol, refined oil, heavy oil, coal-gas, producer-gas, coke-oven gas, and blast-furnace gas, but for marine purposes generally producer gas and heavy oil are at present the only available fuels. The special conditions required for a successful marine engine are:—(a) the engine must be reversible; (b) it must be capable of being quickly

stopped and of being quickly started, either ahead or astern, (c) it must be capable of being promptly speeded to any desired point between full speed and dead slow, which latter speed ought not to be greater than one-quarter of the full speed, (d) it must be capable of working well, not only in smooth water, but in heavy weather in a seaway in which the varying immersion of the propeller causes rapidly changing conditions of resistance In marine engines the revolutions are practically proportional to the speed of the ship, and as the vessel's resistance increases much more rapidly than the speed, it follows that for a reduction of speed of revolution the mean effective pressure must be reduced much more than in proportion to the revolutions This is a much more difficult problem in marine engines, where no fly-wheel is practicable, than on land, where the use of a heavy fly wheel permits the suppression of alternate fuel charges

A LITTLE essay of twenty-four pages has been published by M Prosper de Lafitte on "The Magic Square of *n* with *n* Numbers" By this is meant a square with n^2 spaces, containing the numbers from 1 2, 3, *n* each repeated *n* times in such a way that each row each column and each diagonal contains each number once. This is, of course a slightly different problem from that of the ordinary magic square which contains all the numbers from 1 up to n^2, and the author's claim to have produced a paper calculated to instruct as well as to entertain the reader is well justified Messrs Gauthier-Villars of Paris are the publishers

IN the *Atti dei Lincei* xv, 10, Dr Pietro Macchia discusses the relations between thermal conductivities at ordinary and at low temperatures In determining the conductivity, observation is made of the distribution of temperature in a rod subject to surface radiation when the flow of heat has become steady Even at moderate temperatures results based on Stefan's law are shown to be better than those derived from Newton's law of cooling Thus for pure lead, the ratio of the conductivities deduced from Stefan's law, for temperatures 18° and 100° respectively, works out at 1 016, Jäger and Diesselhorst's determinations, based on the consideration of non-stationary states give 1 015 while the assumption of Newton's law gives 2 01

MESSRS A E STALEY AND CO, of 19 Thavies Inn Holborn Circus, E C, have submitted for our inspection a pair of their new "Nikos," 8×, prismatic binoculars which are sold at the low price of 6*l* 10*s* The instrument is beautifully finished in Russia leather, and is of a very compact, light, and handy form whilst its performance optically satisfied the critical tests to which we subjected the pair examined There is a common focussing screw for both eye pieces, one of which is fitted however, with a separate arrangement, and the bending bar is adjustable to the distance between the observer's eyes by simply bending it the required amount Both the special focussing arrangement and the bending bar are provided with scales so that the habitual user may adjust the glasses before using them without having to make a series of trials each time A pair of studs projecting from the object-glass end of the glasses enables the latter to stand flat on any horizontal surface

THE issue of "Hazell's Annual" for 1907 is now available The alphabetical arrangement of this cyclopædic record reduces the trouble of reference to a minimum, and the comprehensive character of the contents makes the volume of wide interest

A THIRD edition of "The Mechanism of Weaving," by Mr Thomas W Fox, of the Manchester Municipal School of Technology, has been published by Messrs Macmillan and Co, Ltd The opportunity has been taken to revise the text carefully, to add matter relating to recent developments in weaving, to introduce numerous new illustrations, and generally to enhance the value of the work from the points of view of teachers, students, and men actively engaged in the cotton industry

THE thirteenth edition of "Practical Sanitation," by Dr George Reid, has been published by Messrs C Griffin and Co, Ltd The appendix on sanitary law, by Mr H Manley has been entirely re-written, and other parts of the work have undergone detailed revision, particularly the chapter which deals with sewage disposal The work provides medical officers of health, sanitary inspectors and others interested in sanitation with a comprehensive survey of the practical and scientific aspects of sanitary science

WE have received a copy of the first number of the *African Monthly*, a magazine to be devoted to literature, history, exploration, science, and art, as well as fiction The new periodical is published by the African Book Company Ltd of Grahamstown Cape Colony, and its price is 1s The contents of the first issue are varied and interesting, scientific subjects are represented by two articles "The Bantu in the Tenth Century As described in Extracts from the 'Golden Meadows' of Al Mas'udy," by Mr W Hammond Tooke, and "Merino Sheep Breeding in Australia," by Mr R H Harrowell The magazine may be obtained in this country from Messrs Wm Dawson and Sons Ltd, Cannon House, Breams Buildings, London, E C

OUR ASTRONOMICAL COLUMN

THE RECENT TOTAL ECLIPSE OF THE SUN —A telegram received by Prof Kreutz from Prof R Schorr at Dschisak in the province of Samarkand, states that during the whole time that the sun was eclipsed on January 14 the sky was totally obscured, and snow fell heavily Only meteorological and some photometric observations were possible (*Astronomische Nachrichten*, No 4150)

Herr Archenhold has received a similar message from another observer at Samarkand, whilst the Moscow observers are reported to have obtained no results even in the meteorological and photometric programme (*Das Weltall* January 15)

THE SOLAR RADIATION —The depression of the "solar radiation" during 1903, as observed at Warsaw, is dealt with in a paper communicated to the *Bulletin météorologique du Département de l'Hérault* by M Ladislas Gorczyński The observations showed that between December, 1902, and February, 1904, the radiation was abnormally low as compared with the mean for the years 1901–5 This phenomenon has previously been commented upon by various observers, and is supposed to have been due to the large amount of volcanic dust in our atmosphere Two other abstracts from the same bulletin deal respectively with the variations of the intensity of the solar radiation with the height of the sun, and the amount of the insolation at Warsaw, Treurenberg, and Montpellier

PHOTOGRAPHS OF GIACOBINI'S COMET (1905c) —The way in which a comet's tail develops as the comet approaches perihelion is beautifully shown by a series of photographs of Giacobini's 1905 comet which are published in Bulletin No 25 of the Lowell Observatory The series extends from December 14, 1905—eight days after the comet's discovery—when the object showed only a well-defined nucleus, to January 7, 1906, when three distinct tails are shown, the middle one extending to a distance of 10° from the head

On December 29 two tails were shown, one of which was made up of four distinct streamers with nebulous matter between them, two of these streamers were crossed so as to present a twisted appearance, whilst the two outside ones diverged in the usual manner On no two negatives are the images the same, the day-to-day development being very marked Between January 3 and 4 there was a decided change in the position-angle of the extremity of the tail, which is shown in a striking manner by the superposition of the two orientated images, and is somewhat similar to that recorded by Prof Barnard in the case of Brooks's comet 1893 iv

THE RED SPOT ON JUPITER, 1905–6 —The results of Mr Stanley Williams's observations of the Great Red Spot during the opposition of 1905–6 appear in No 4150 of the *Astronomische Nachrichten* The transit times of the spot were all observed by simple eye estimates, care being taken to avoid looking at the Red Spot Hollow, which as compared with the spot itself, was a very conspicuous feature The rotation period as determined from 635 rotations, was found to be 9h 55m 41 46s, a value slightly less than that determined from the 1904–5 opposition The mass of dark material which circles round the belt in which the spot is situated overtook the spot during the last week in March 1906

Micrometer measures made during the period November 1905, to February 1906 showed the mean longitude of the Red Spot Hollow to be 29° 41 a position some 1° 3 following the spot itself Mr Williams discusses the relative accuracy of the micrometer method at some length and from his experience, arrives at the conclusion that it is likely to introduce errors due to the alteration of the appearance of the observed feature caused by the superposition of the micrometer wires a conclusion which is confirmed by other observers of Jovian phenomena

A PECULIAR SHORT-PERIOD VARIABLE (155 1906 CASSIOPEIÆ) —From a number of observations made at Potsdam during 1906, Messrs Müller and Kempf find that the sixth magnitude star B D +68° 200 is a variable, with a period of 1 95 days and a remarkably small range of light variation the whole amplitude amounting to only 0 33 magnitude (*Astronomische Nachrichten*, No 4148)

THE BRITISH SCIENCE GUILD

THE first annual meeting of the British Science Guild was held at the Mansion House on Monday, January 28 Just fifteen months have passed since the inauguration of the Guild in October, 1905 and the very large gathering of sympathisers with the new movement was eloquent of the fact that the hopes and confident expectations of its organisers have not been disappointed The Lord Mayor Sir W Treloar, presided, and was supported by the president, the Right Hon R B Haldane and Sir Norman Lockyer the chairman of committees Many eminent representatives of science, industry, and the educational world were present

The Lord Mayor having opened the meeting by offering a warm welcome to the Guild, Sir Norman Lockyer gave an outline of work accomplished since its inception, touching on the main points mentioned in the report of which the following is an abstract The first part was purely historical. It stated what the committees have done Though their activities have not figured so prominently before the general public outside, it must be remembered that the more important the work was going to be, the more quiet must it be in the first instance The first public outcome of the Guild was connected with the report of the Departmental Committee appointed to consider the question raised by the proposed new Technological Institution at South Kensington, and the fear that the scheme might be delayed in consequence of certain differences of opinion as to the constitution of the governing body The result was the letter to the *Times* last year, in which the Guild urged most strongly that neither the question of the ultimate and final relationship of the new institution to London University nor any other matter should be allowed to interfere with the immediate appointment of at least an organising governing body

The next important point to which the report refers was that of the grant to the National Physical Laboratory it described the happy result of Mr Haldane's interposition with the Treasury in obtaining an increase of the grant from 5000*l* to 10 000*l*

At the request of various bodies the Guild has taken part in several important deputations Sir John Cockburn represented the Guild on a deputation to the President of the Board of Trade urging the importance of the compulsory working of patents

On account of certain changes contemplated by the Government, the council of the Royal Society of Edinburgh asked for the support of the Guild in the matter of obtaining suitable buildings to house the society, and also a suitable grant for yearly expenses This support was most cordially given by the executive committee The sum originally proposed to be expended by the Government on the new buildings was 14 000*l*, but the final result of the action of a committee and of the representations made by the deputation on which the Guild was represented by Sir W Ramsay, K C B, was to secure for the society a sum of 25 000*l* for the purchase of a building, 3000*l* to cover the expenses of fitting it up and a yearly grant not exceeding 600*l* a year The council of the Royal Society of Edinburgh has expressed the opinion that these arrangements are quite satisfactory (see p 205)

Several communications were received from the officers of the Marine Biological Association urging the Guild to form part of a deputation to the Chancellor of the Exchequer on the subject of the continuation of the grant in aid of the International Fisheries' Investigations Sir Michael Foster, K C B, was nominated to represent the Guild on the deputation which introduced by the Right Hon Austen Chamberlain, M P was, in the unavoidable absence of the Chancellor of the Exchequer, received by the Parliamentary Secretary, Mr McKenna M P on December 18 1906 (see p 185)

In June the Guild received a communication from the anthropometric committee of the British Association in relation to a deputation to the Prime Minister urging him to appoint a commission to carry out a periodic anthropometric survey of school children and adults It is proposed that this commission shall be constituted on the same lines as the advisory council recommended by the Physical Deterioration Committee and preferably should be under the direct control of the Prime Minister like the Defence Committee The proposed anthropometric survey would also be on the lines recommended by the Physical Deterioration Committee The executive committee considers the proposed survey is a most important application of science to statecraft and has nominated a representative of the Guild to attend the deputation which the Prime Minister has consented to receive after the recess

The education committee has had before it a proposal to form two new committees, one dealing with elementary and secondary education especially in relation to the introduction of leaving certificates from the primary school and the importance of practical scientific training in both It was proposed that the second educational committee should consider the question of an increased endowment of universities by the State Referring to this committee Sir Norman Lockyer remarked that the private endowment of American universities last year amounted to five millions sterling It is hard for us as a nation to compete with that Germany is strengthening its universities just as thoroughly as it is strengthening its Fleet a reminder that we ought to be able to compete with other nations in the preparation and equipment for industrial progress as well as for war

The report recorded the overtures made to the Franco-British Exhibition Committee as the outcome of which the exhibition committee's desire to include science in their programme was stated The assistance of the Guild was asked in the formation of the science section and it was now proposed that lectures should be given during the continuance of the exhibition by British and French men of science

The progress of the Guild was indicated by the membership of 590, and by the fact that already branches are being formed in Canada and Australia

Mr Haldane then rose to move that the record of action summarised in the report be approved He endeavoured, first, to answer a possible criticism of this record Some might think that it was not startling or striking, and foretold no revolution to be effected But the founders of the Guild never believed that progress could come rapidly Nothing but strenuous labour in educating the public would bring home to the public mind the depth and reality of the conviction on which this British Guild of Science was based, that Knowledge was Power Nevertheless, Mr Haldane disavowed a pessimistic outlook There was much that was encouraging Go where they would, applied science was taught in a fashion in which it was never taught a few years ago, and he instanced three universities which he had himself recently visited—Glasgow, Manchester, and Liverpool, at Birmingham and London also the tendency was not less visible We did not notice it, but it had been noticed by the Continent "I have been struck more than once by the emphatic testimony given by Continental experts to the progress which has taken place in Great Britain, which is, they say at the present time, relatively speaking, more rapid than the progress in other parts of the world Well, we have much to make up America has been ahead of us and I do not think it is only endowment I think it is the practical spirit of the American people which has made them realise how essential it is to a country which is leading the industrial world that the best science should be at the disposal of all the manufacturers. Canada herself is in some respects ahead of this country There is a technical equipment in the McGill University, Montreal, the like of which we hardly know, and it is not contrary to what one likes to see that our own young men should be taking advantage of the opportunity which that University offers to go and get the highest training in some branches of applied science under the British flag "

Mr Haldane attributed some good in this respect to the fiscal controversy It was demonstrated that we had gone back, because we were using antiquated methods in competition with those who used new and more scientific methods All this had stirred up many of our great captains of industry and to-day brains had a better market than they had had for a very long time past in Great Britain Reviewing all these things Mr Haldane thought they ought to make us hopeful Scientific education was no longer at a discount He directed attention to his own department of administration at the War Office, for this new movement was not confined merely to private industry, we train our young officers he said, as they were never trained before and we have an average of scientific attainment among our young officers such as has not been seen at any previous time in the British Army Then he pointed out another thing which he thought, lent itself to the objects of the Guild and that was the extent to which the private employer is giving way to the joint-stock company The joint-stock company had its disadvantages but under it more and more the price of brain was the price which was paid to the manager, and less and less to the private capitalist More and more science was thus levelling opportunity, and giving to everybody the chance of making himself a power among his fellow-men

Mr Haldane concluded his interesting speech with these words on the relation of the State to science —" All this costs money, and if the State is to play its part in it, it must cost the State money Well, but the national income is increasing These very things give a reward which is four-fold or ten-fold more than the expenditure necessary to earn it There are those who put our national income somewhere between 1600 millions and 2000 millions at the present time Well, our expenditure under the Imperial Government is well within 10 per cent even if you take the lowest of those figures, and surely 10 per cent is not much for a people to contribute to get advantages so enormous as we see on every side to-day Education, improved surroundings equality of opportunity to a degree we have never known before, increase of the national production—all these things are well worth purchasing at an expenditure which means only a fraction of that 10 per cent, and I say that if the State only spends its money wisely the State will make no better investment for those for whom it is responsible than an adequate expense on the development of scientific method Our problem is to awaken our country There are many others engaged in that work This Guild is only one of several organisations, but it contains on its roll perhaps more distinguished men of science than any other society which is engaged in a like work Our business is to act in the true missionary spirit, and, acting in the true missionary spirit, we have to see to it that our energies do not flag and that we do not allow the sun to go down before our labours are complete "

The Hon and Rev E Lyttelton, the headmaster of Eton College, followed Mr Haldane He had been astonished at the zeal shown by the committee, and his agreement with the previous speaker's hopefulness was shown by the remark —" I have never yet taken part in any movement which seemed to me so absolutely certain to have a lasting and deep effect upon the life of the country than this one " He was greatly struck with the progress of the scientific spirit in the educational world There was no subject now taught in schools in the same way as it was taught in schools thirty years ago " If that has been done at a time when many schoolmasters have been vocal with indignation at the encroachment of science on their private domain, how much more will be done in the next thirty years, when we have grown wise enough to see that whatever be the blessings of a literary education, there is not the slightest reason why in every school there should not be a combination of literary education with scientific training " This much-agitated conflict between literature and science in university circles was commented on in a striking way by a later speaker—the Vice-Chancellor of Cambridge University Dr F S Roberts The Vice-Chancellor of Oxford University was, unfortunately, unable to be present, but Dr Roberts pointed out as a happy omen the fact that that gentleman, as well as Mr Lyttelton and himself, were all representatives of literature and yet were all very keen advocates of science

Mr Alfred Mosely offered some interesting remarks on the teaching of science in America, and Prof Meldola took the opportunity of correcting a notion which existed in some quarters that the Guild was specially interested in the practical and industrial application of science He wished to see the encouragement of scientific method as a cult The work of the Guild, he hoped, would be to raise the level of public opinion towards abstract science itself The rest would follow

The other business resolutions included one to permit of distinguished Americans and foreigners being elected honorary members—an extension of the basis of the Guild due to the courtesies and offers of information from eminent Americans

The following executive committee for the ensuing year was elected The new members are indicated by italics — *President*, Right Hon R B Haldane, M P , F R S , *hon treasurer* Right Hon Lord Avebury, F R S , *hon assistant treasurer*, Lady Lockyer, *trustees*, Sir James Blyth, Bart , Mr C W Macara , *vice-presidents*, *Sir Archibald Geikie*, F R S , Sir John Wolfe-Barry, K.C B , F R S , *chairman of committees*, Sir Norman Lockyer, K C B , F R S *vice-chairmen of committees*, *Sir William Ramsay*, K C B , F R S , Sir Lauder Brunton, F.R S , Hon Sir John Cockburn, K.C.M G , *Sir Philip Magnus*, M P , *hon secretary*, *Sir Alexander Pedler*, C I E , F R S , *members*, Sir Hugh Bell, Bart , Mr G T Beilby F R S , Right Hon. Thomas Burt, M P , Mr. Dugald Clerk, Captain Creak, C B , R N , F R S , Dr Francis Elgar, F R.S , Prof Meldola, F R S , Sir William Mather, Major-General Sir F Maurice, K C B , Prof J. Perry, F R S , *Sir William White*, K.C B., F.R S., Mr Carmichael Thomas, Mr. F. Verney, M P., Sir Henry Trueman Wood, *Sir Edward Brabrook*, C.B.

The following new vice-presidents were appointed:— Lord Reay, president of the British Academy; President Warren, Vice-Chancellor of the University of Oxford; the Vice-Chancellor of the University of Cambridge; Sir Frederick Pollock, Bart., and Sir David Gill, K.C.B., F R S

AMERICAN FOSSIL CYCADS[1]

THE wonderful state of preservation of many Palæozoic plants, which has enabled us to gain much valuable information in regard to phylogenetic problems is in marked contrast to the general absence of petrified fossils afforded by Mesozoic strata Thanks to the ability and energy of Mr G R Wieland, liberally backed by the Carnegie Institution, a flood of light has been thrown on the morphology of an extinct group of Mesozoic gymnosperms, which it is possible to study with a precision and thoroughness hardly to be surpassed in the case of recent plants Mr Wieland's monograph, with its splendid set of large plates, is an addition to botanical literature of exceptional importance After reading the volume, we couple with a grateful acknowledgment of what has already been done an earnest wish that the results of further investigations may be presented in an equally attractive form in the near future.

Mesozoic plant-bearing rocks in almost all parts of the world are characterised by an abundance of pinnate fronds, recognised by Brongniart and by other pioneers of palæobotany as cycadean on account of their close agreement in external characters with those of modern cycads—a small group of tropical gymnosperms occasionally extending into subtropical regions, which constitute an unobtrusive assemblage of survivals from a remote past Stems which might reasonably be supposed to have borne these fronds have until recently been met with in a few localities only, and never in great quantity, except, perhaps, in the Purbeck beds of Portland As Wieland says, it is with the work of the English botanists Carruthers and Williamson (1868) that the exact investigation of fossil cycadean stems "may be said to have fairly begun" The famous species *Bennettites Gibsonianus* of Lower Greensand age, discovered many years ago in Luccomb Chine in the Isle of Wight, first described by Mr Carruthers and afterwards by Prof Graf zu Solms-Laubach, has made us familiar with the striking differences between the reproductive shoots of this extinct type and those of existing cycads, differences of surprising magnitude in view of the close resemblances as regards habit and vegetative anatomy Other European examples of Bennettites have been described by Profs Cappellini and Solms Laubach, and an exceptionally well-preserved French Liassic species by Prof Lignier, of Caen In 1860 Philip Tyson discovered a few silicified cycadean stems in the Potomac formation of Maryland, but these were not submitted to more than a superficial examination, it was not until the last decade of the nineteenth century that the late Prof Marsh, of Yale, with an energy worthy of a pupil of Goeppert, secured a collection of more than 700 petrified stems from the Upper Mesozoic rocks of the Black Hills of Dakota and Wyoming European botanists who have had an opportunity of seeing some of these relics of cycadean groves of the Upper Jurassic and Lower Cretaceous periods in American museums have eagerly waited for the publication of Mr Wieland's investigations, and the preliminary papers which he contributed to the *American Journal of Science* (1899–1904) served to intensify the impatience with which the more complete descriptions have been awaited

In chapter i the author gives an interesting summary of collections of cycadean stems, chapter ii is devoted to their preservation and external characters In chapter iii we read of the difficulty of attacking these enormous flint-like fossils, and of the ingenuity by which the silicified trunks were made accessible to minute examination Tubular drills were found to afford the best results, photographs of some of the drilled stems remind one of cylindrical cheeses to which the taster's scoop has been freely applied

Chapter iv, treats of internal structure, many of the facts recorded merely confirm what was previously known, but additional information is given in regard to the anatomy of vegetative organs which makes us wish for further details in regard to many points still left in doubt or incompletely dealt with We should like to know more about the relative abundance of centrifugal and centripetal wood in the leaf-traces, we are curious to know whether the Bennettites stems usually possessed one cambium-zone or several, and it would be interesting to have more definite statements as to the histological characters of the secondary wood It is not improbable, as Mr Wieland suggests, and as the writer suspected from an examination of a silicified cycadean stem from India, that these Mesozoic stems, in some cases at least, differed from modern cycads in the greater compactness and hardness of their wood No one recognises more fully than Mr Wieland how much remains to be done, and he promises to do his best to fill up these and other lacunæ In chapter v we have an exceedingly interesting account of the vernation and structure of young fronds preserved in buds on the main trunk It is a curious fact that, despite the extraordinary abundance of stems, detached fronds have not been found in the enclosing strata, a circumstance which enhances the value of the discovery of unexpanded pinnate leaves in organic connection with the stem

FIG 1 —*Cycadeoidea Marshiana* Longitudinal section through ovulate strobilus s = remnant of dehiscent disc of microsporophylls

It is, however, in chapters vi and vii that we find by far the most important part of the author's work The researches of Carruthers and other authors have shown that Bennettites did not bear terminal, or in some cases apparently terminal, flowers as do the true cycads but produced axillary branches consisting of a comparatively short axis ending in a terminal receptacle crowded with two sets of appendages, slender stalks terminating in single orthotropous seeds associated with sterile organs probably homologous with the seed-bearing pedicels, termed interseminal scales, which overtopped the small seeds and almost completely enclosed them in a protecting envelope These axillary shoots usually occur in profusion on a single stem, and, as Wieland points out, often in approxi-

mately the same stage of development, it may be, as he suggests, that the plant did not fruit until reaching maturity. The seeds of Bennettites are in size like "small grains of rye", they seem to be exalbuminous, and have little in common with the enormous seeds of recent cycads. With the exception of a single Italian species, in which Solms Laubach found a few pollen grains associated with a female flower, we were in complete ignorance as to the nature of the male flowers until the publication of Wieland's results. It was usually assumed that in Bennettites, as in true cycads, the flowers were unisexual. Whatever interpretations we put on the morphological value of the interseminal scales and seed-bearing pedicels, it is clear that the female flowers of the fossil genus are characterised by a morphological plan far removed from

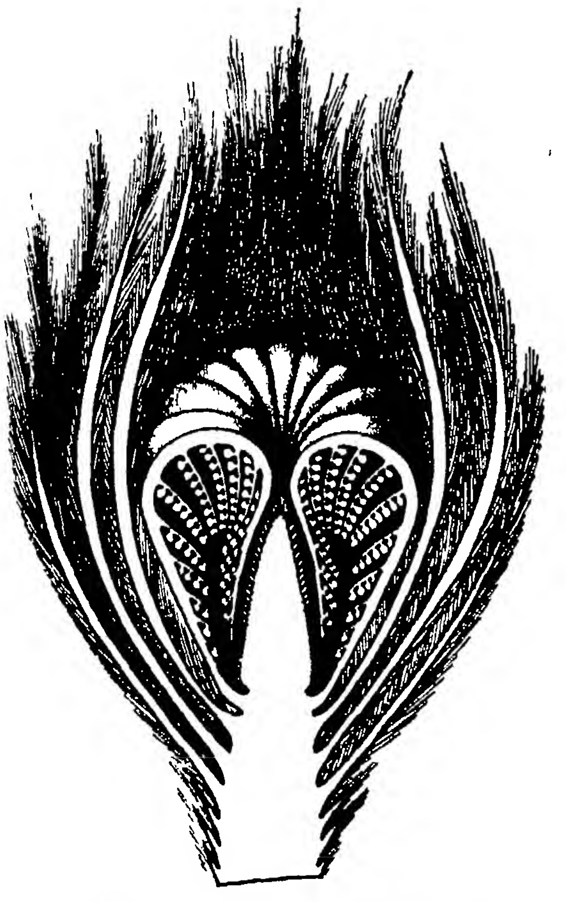

FIG. 2.—Restoration of unexpanded bisporangiate strobilus showing enveloping bracts, folded microsporophylls and conical receptacle bearing short ovuliferous pedicels, &c.

that of the leaf-like carpels of Cycas and from the crowded carpellary scales of other recent genera.

Mr. Wieland has conclusively proved that previous views as to the unisexual character of the Bennettites flowers are incorrect; in most cases, at any rate, the flowers were bisexual. He figures several examples of reproductive shoots terminating in ovulate flowers like those of *Bennettites Gibsonianus* bearing a basal rim (Fig. 1, s) to which was formerly attached a hypogynous whorl of pinnate microsporophylls with pinnules reduced to an axis producing numerous synangia and microspores. This assumption as to the former association of microsporophylls with a central group of ovuliferous pedicels is justified by the discovery of numerous examples of bisexual flowers, consisting of an axis terminating in a conical receptacle bearing the two sets of organs characteristic of what have previously been styled female flowers, but differing in the smaller size of the seed-stalks and interseminal scales, and presenting the appearance of partially aborted or immature female organs. Surrounding this central receptacle there is a whorl of several pinnate leaves with their upper portions folded inwards between the petioles of the central gynœcium (Fig. 2), and bearing rows of synangia of a type but little removed from those of modern marattiaceous ferns. No specimen has so far been described of a bisexual flower in which both andrœcium and gynœcium are mature. There appear to be two possible explanations: are these bisexual flowers comparable with the male flowers of Welwitschia (Tumboa), in which the female portion is functionless, or have we a case of dichogamy, in which the male organs matured first, and were subsequently shed? This discovery, first announced in a short paper by Mr. Wieland in 1899, is of the greatest importance as demonstrating the retention in a comparatively little altered form of filicinean synangia and spores of the marattiaceous type side by side with female organs which foreshadow the angiospermous gynœcium. It is impossible in the space at our disposal to attempt to deal with the numerous questions of phylogeny—the probable line of evolution of the Bennettitales and their relationship to modern cycads—but we naturally ask, Is it fitting to speak of plants possessing this type of flower as cycads? The term cycads used by the author is perhaps justifiable if adopted in the widest sense, but the reviewer cannot help feeling in sympathy with a view expressed in a letter recently received by him from Prof. Nathorst, of Stockholm, that the extension of the designation cycads to plants so far removed in the organisation of their essential organs from the cycads as we know them necessarily tends to minimise the importance of fundamental differences.

The generic name Cycadeoidea, proposed by Buckland in 1827, is used by the author in preference to Carruthers's genus Bennettites; it would, we think, be better to retain the latter name for all cycad-like stems possessing the lateral fertile shoots of the type originally described by Mr. Carruthers. There is another very different form of stem which Nathorst discovered in the Rhætic plant beds of Scania bearing fronds long known as a species of Anomozamites and flowers which probably agreed closely with those of Bennettites. This stem, which Nathorst names *Williamsonia angustifolia*, is important as demonstrating the wide range of vegetative variation within the great group Cycadophyta. The discoveries of Mr. Wieland, Prof. Nathorst and others demonstrate the impossibility of forming any adequate conception of the nature of the Cycadophyta—to use Nathorst's convenient term—if we confine our attention to the meagre remnant of that phylum which has survived the revolutions in the plant kingdom since the beginning of the Cretaceous era.

In the concluding chapters Mr. Wieland deals with questions of phylogeny; while recognising much that is suggestive in the treatment of this difficult subject we feel that there is a certain vagueness in his conclusions which, though partly due to lack of data, is perhaps to some extent the result of a want of clearness and conciseness of treatment. The initial difficulties have, however, been surmounted, and Mr. Wieland has completed with conspicuous success a very important section of the work; we close the volume with a desire for more, and heartily wish the author further success in a field where the opportunities are unrivalled. A. C. S.

THE RECENT HIGH BAROMETER

A REGION of exceptionally high barometer readings over western Europe was a feature of especial interest during a great part of January, the mercury in many places attaining to a greater height than any previous record, while elsewhere the readings have scarcely been exceeded. To trace the history of this anticyclonic region and to attempt any explanation requires a series of synchronous and synoptic charts embracing a large part of the northern hemisphere; possibly this may be undertaken by one of our European weather offices when all the facts have been collated. It would seem that vessels traversing the Atlantic have in many cases experienced

barometer readings much in excess of the average during the whole voyage, and for the greater part of the month.

As early as January 4, a region of high barometer, with readings 30·4 inches, spread in over the Bay of Biscay from the Atlantic; this gradually extended eastwards over south-western Europe, and on January 12 the region intensified, readings of 30·7 inches occurring over the Bay of Biscay and western France. The anticyclone maintained its ground, and on January 17 and 18 was distinctly spreading northwards, the isobar of 30·5 inches embracing France, England, Denmark, and the greater part of Norway and Sweden. On January 20 the anticyclonic area was greatly augmented, apparently by an independent region of high barometer spreading down from the extreme north of Europe. The highest readings—30·9 inches—were situated over Lapland and Finland, and on January 21 the highest pressure was in the vicinity of the White Sea, the barometer at Archangel reading 31·39 inches. On January 22 the anticyclone was central over northern Russia, the barometer at Kuopio standing at 31·46 inches. The maximum height of the barometer was attained on January 23, when at Riga the reading was 31·58 inches, and the region of 31 inches and above embraced parts of England, Scotland, and Ireland, the barometer at some of the stations in the British Islands being higher than any previous record. The high barometer area continued to travel southwards, and on January 26 the centre was in the neighbourhood of Constantinople but the highest reading had then decreased to about 31·1 inches.

The absolutely highest reading of the barometer on record is 31·72 inches, which occurred at Irkutsk on December 20, 1896, and at Semipalatinsk on December 16, 1877. The highest in the British Islands is 31·11 inches, at Aberdeen on January 31, 1902, and 31·10 inches at Fort William on January 9, 1896. The lowest reading on record at the surface of the earth, and reduced to sea-level, is 27·12 inches, at False Point on the coast of Orissa, on September 22, 1885, and the lowest in the British Islands 27·33 inches, at Ochtertyre on January 26, 1884.

From about January 20 to January 26 the weather was intensely cold over western Europe, and an easterly wind was blowing for the most part. The Weekly Weather Report issued by the British Meteorological Office shows that, for the week ending January 26, the mean temperature was 9° F. below the average in the midland, southern, and south-western districts of England, and the deficiency amounted to 7° F. in several other districts. The minimum temperatures were as low as 5° F. and 10° F. in many parts.

STAR CATALOGUES [1]

SOME astronomical work is so attractive that it readily finds support and imitation. The preparation of star catalogues scarcely belongs to that category. Such work is dreary and monotonous and those who devote themselves to it are entitled to the acknowledgment that is invariably granted to those who are willing to sacrifice brilliancy to utility. There is little scope for the exercise of originality. Once the scheme is defined, the stars selected, and the needed accuracy attained, there is nothing to break the wearisome repetition of a purely mechanical process. The work can hardly be said to possess the attractiveness of permanence. The observations give the position of the stars at a certain epoch, and almost before the catalogue is available as a whole the work of supplementing it has begun. The wayward and lawless proper motions of the stars tend to render the coordinates obsolete, and this cause alone will necessitate the repetition of the work upon which so much labour has been bestowed. Yet no work requires more care and forethought, and this will be painfully evident to those who read the introductions to the several works, the titles of which are quoted below. It will be equally evident to those who recall the names of those who have devoted themselves to this work, and who will thus be reminded that many astronomers, from Flamsteed to Airy, have been content to stake their reputation upon their contributions to the cataloguing of star places. It is the opportunity for the introduction of greater accuracy that affords the necessary compensation. Sir David Gill, than whom few can look back upon the accomplishment of a greater mass of work, probably views the completion of these catalogues with very considerable satisfaction, and regards them as rounding a well-filled career.

The usefulness of a catalogue will be more readily appreciated if the star places are required to make accessible other material to which it is at present impossible to give a final and convenient form. This is the case with the first of the catalogues on our list. The 8560 stars are not isolated points irregularly distributed over the sky but are generally the brighter stars to be found in the zone allotted for observation to the Cape of Good Hope Observatory by the Astrographic International Congress. These stars form the fiducial points to which the unknown stars of the photographic plates will be referred. The coordinates, determined on one plan, will give great uniformity to the resulting photographic catalogue. All the observations have been made between 1896–9, and since the plates have been taken approximately within the same years, possible errors arising from proper motion are effectually eliminated. Moreover, the advantages arising from employing stars taken at one epoch and observed on one uniform plan are patent. Apparently, in the use of facilities for reducing photographs, observers in the southern hemisphere were at a disadvantage compared with those in the northern, since the latter could immediately bring into use the admirably arranged catalogues of the Astronomische Gesellschaft, but the pains bestowed by Sir David Gill upon this piece of work have entirely reversed the conditions, and placed the Cape Observatory in the most favoured position, for, to a certain extent, he is able to select those stars for the reduction of his measures which are most suitably arranged upon the plate. The northern observers have to accept such stars as have been observed, but in forming a new catalogue, one would naturally observe those stars which will furnish the best data for subsequent reduction. An ideal scheme would be to select for each plate eight stars distributed uniformly round the circumference of a circle of about 55′ in diameter the centre of which coincided with the centre of the plate, and in addition, two stars near the centre of such plate, but owing to overlapping whereby the four corners of one plate become the centres of four other plates, such a scheme does not work out practically, and on the average twelve or thirteen stars, somewhat irregularly situated, will be available for the reduction of each plate, and this number may rise to seventeen or eighteen stars.

The individual results on which the catalogue places rest have been published in the annual volumes. The details here presented enable one to follow the small corrections that have been introduced to eliminate systematic errors and to secure uniformity throughout. To the ledgers of right ascension three terms have been applied, one to reduce the right ascension to what it would have been if Newcomb's system had been adopted, a second correction, depending on magnitude, is required to reduce the R.A. of a particular star to what the observer would have recorded if the star had been of the fourth magnitude. The necessity of the third correction is not very clear. It has been required because of the small number of clock stars employed in each zone, "and perhaps also because of small outstanding errors in the adopted values of Level, Collimation, and Azimuth."

In order to obtain the greatest possible accuracy in the declinations, a system of small corrections has been applied

"Astrographic Catalogue 1900·0, Oxford Section, Dec. +24° to +32°. From Photographs taken and measured at the University Observatory, Oxford, under the Direction of Prof. H. H. Turner, F.R.S." Vol. i. Pp. lxvi+123. (Edinburgh: Printed for H.M. Stationery Office by Neill and Co., Ltd., 1906.)

to the values in the annual volumes. These corrections are again three in number —one required by the Chandler change in latitude, a correction depending, apparently, on some function of zenith distance, and which embraces flexure of the telescope and circle, and removes small uncertainties in the refraction tables The necessity for the third correction is a little obscure It is asserted to be necessary on account of small possible errors in the determination of the nadir, or to remove errors arising from abnormal refraction or irregular heating or flexure of the instrument More details as to the manner in which the last correction has been derived would be welcome It is contended that the application is justified, since the amount of the probable error of observation is reduced

A feature of great interest is the comparison between the final places of the catalogue and those given in the earlier Cape catalogues or by other authorities The main object is, of course, to derive the proper motion, but the real interest centres in the systematic deviations from other catalogues, mainly in the discrepancies shown by those of Cordova It is impossible within narrow limits to do justice to this discussion, but the points raised are of the highest importance in observational astronomy, and exercise considerable influence on some questions of cosmical interest

The second work on our list contains four catalogues Two of these are quite small, and can be dismissed forthwith One contains nearly a thousand stars culminating south of the zenith of the Cape Observatory This list includes all stars brighter than 8 5 magnitude which are in the Cape Photographic Durchmusterung, but not in any catalogue of precision, also stars observed with comets or used in survey operations The main portion, consisting of 3365 stars culminating north of the Cape zenith, is of more interest and importance The greater number of the stars is due to the prosecution of a scheme submitted by Sir David Gill to the Comité international des Etoiles fondamentales with the view of forming a zodiacal catalogue sufficiently wide to permit the determination of the moon's place at any observatory and in any part of its orbit by heliometer measures of the distance and position angle of a lunar crater from suitably surrounding stars or of determining in a similar way the position of any of the larger planets Of course, it is not possible to determine with the highest accuracy all stars which may be employed for such purposes, but it is hoped that by concentrating the attention of meridian observers on a select number of stars suitably situated and by adopting processes likely to eliminate systematic errors a very considerable improvement in accuracy may result Several observatories have shown their approval of the scheme by taking part in the observations, and it is hoped that an adequate determination of star places for 1900 will be the outcome, while observations repeated at intervals of twenty-five years would provide all the data required for the most rigorous determination of the places of moon and planets

The third work is different in its design and more comprehensive in its plan The star positions for which the means of reduction are supplied number no less than 65,750, and when it is remembered that these stars are situated in a narrow zone, two degrees in width on the small circle of 31° dec, we are able to learn something of the magnificence of the scheme which proposes to treat the whole sky on a uniform plan What strikes one with the most force is the fact that a small observatory, the funds of which are necessarily strictly limited by the many demands that are made on the university chest, has been able to carry to a successful issue a scheme of such magnitude has competed with the resources of great national observatories, and has found itself second to none Prof Turner has exhibited qualities of administration of the highest order He has known how to impart to a comparatively untrained staff the enthusiasm which he himself experienced, and to secure in every part of the work that uniformity of excellence and rigorous accuracy which are essential for the maintenance of its international repute To him and to the little band which has nobly seconded his efforts we can only offer our heartiest congratulations.

Since Prof Turner has recalled in the most prominent manner to what extent the scheme has benefited by those who were responsible for the conduct of the observatory in the past, it is not out of place to record here that it was the well-placed generosity of Warren de la Rue that enabled the University of Oxford to play a worthy part in the plan which has been brought to so happy a completion It is encouraging to remember that the energy of the late Prof Pritchard was not exhausted, and that, at the age of seventy-nine, he could contemplate embarking upon a new and arduous enterprise. This is the first volume of eight that will appear, and there can be no hesitation in saying that the completion of such a work amply justifies the existence of the University Observatory Twenty years have passed since de la Rue made his gift, and practically for twenty years the staff of the observatory has been devoted to the completion of this task Some slight conception of its extent can be inferred from the fact that the titles of the papers immediately connected with this subject fill more than three quarto pages

At the end of a long article it is impossible to do justice to the many technical points that are necessarily raised in the introduction It must suffice to illustrate the general policy that Prof Turner has pursued This will enable us better to appreciate the exercise of those qualities of administration which have proved so effective The star images have been measured to the thousandth part of the distance between the *réseau* lines, subtending an angle of 300 seconds in the focal plane of the telescope, or the limit of accuracy has been set at 0″3 This may or may not be the greatest accuracy to which it is desirable to aim, but to have attempted another place of decimals would says Prof Turner, have delayed the completion of the work, with the limited staff at Oxford, for several years, and perhaps imperilled its completion altogether This recognition of his limitations has been amply justified Again, it no doubt required considerable self-restraint to confine the measures to one series of images, since greater accuracy would probably have been obtained if the measures had been distributed over more images rather than confined to repeated bisections of the same, but such a process would involve the additional labour of taking means between quantities which were not similar, and so give additional risk of numerical errors Prof Turner is no doubt warranted in asserting that a just relation has been maintained between the labour expended and the accuracy attained W E P

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —In accordance with the regulations for the administration of the Gordon Wigan fund, the special board for physics and chemistry reports that the first award of the prize of 50*l* from the Gordon Wigan income for physics and chemistry for a research in chemistry has been made to F E L Lamplough, scholar (now fellow) of Trinity College for his research on the determination of the rate of chemical change by measurement of gases evolved

Dr Hobson, of Christ's College, has been appointed chairman for the mathematical tripos, part ii, for the year 1907

A course of lectures on special zoological subjects is being given at the zoological laboratory during the Lent term The course includes lectures by the following — Mr Forster Cooper, on living and extinct elephants, Mr Stanley Gardiner, (1) marine rock formations, (2) the distribution of marine animals, Mr Imms, some recent discoveries in the morphology of insects Mr Perrin, trypanosomes and spirochætes, Mr Potts, parasitism in the Crustacea, Mr Punnett, (1) metamerism, (2) sex, Mr Gadow is lecturing on "Environment and Geographical Distribution of Animals" during the Lent and Easter terms

PROF GEORG KLEBS, director of the botanical institute of Halle University, has been elected to succeed Prof Pfitzer at the University of Heidelberg

DR. REINHARD BRAUNS, ordinary professor and director of the mineralogical Institute of Kiel University, has been appointed successor to Prof H Laspeyres, who retires from the chair of mineralogy and geology in the University of Bonn

THE governors of the Borough Polytechnic recently received an offer from Mr Edric Bayley of 5000*l* towards the estimated cost of the completion of the premises of the polytechnic The governors, therefore, asked the London County Council to assist them by making a grant of 7000*l*, and their request was granted at a meeting of the council on January 23 The cost of the scheme, exclusive of lighting, heating, and equipment, is estimated to be about 11,500*l*

THE annual meeting of the Mathematical Association was held on January 26 at King's College, London The association now consists of 419 members Prof G H Bryan, F R S, was elected president in succession to Prof G B Mathews, F R S During the course of an address, Prof Mathews said he earnestly hoped that the new regulations proposed for the Cambridge tripos would be approved He thinks it will be very unfortunate if, after adopting the principle of the change as the association has done, these regulations are shelved He asked all those who are inclined, from sentimental or other reasons, to vote non-placet on this question to consider carefully whether it is right to do so after this matter has been carefully thought out for many months by men who are representative mathematicians and representative mathematical teachers at Cambridge There is a strong desire at Cambridge to make the mathematical scheme there more living on the one hand, and to bring it more into connection with the general science of mathematics on the other After Prof Mathews's address, papers were read by Prof W H H Hudson on diagrams of anemoids, by Prof A Lodge on contracted methods in arithmetic, and by Mr C S Jackson, on the elementary arithmetic of the theory of numbers

THE current number of *Science Progress* contains an article by Sir Arthur Rücker, F R S, on the economics of university education The essay provides an interesting criticism of Adam Smith's theories of education in the light of modern experience Sir Arthur Rucker leads up to the general criticism that Smith's arguments appear to be based almost entirely on the view that a university is a place where instruction is bought and sold, not a place where professor and student are linked together as leader and follower in a common search after knowledge Incidentally, opportunities are found to insist upon many aspects of education likely to be ignored by the public Thus we read —"as research is largely concerned with the elucidation of the results of hitherto neglected facts, it is found that for many objects mental dexterity can best be fostered by turning the attention of the abler student from the known to the unknown, from information to investigation" In the same number of the review Prof H E Armstrong, F R S, writes on the reform of the medical curriculum, treating it as a problem of technical education Prof Armstrong says that so far as chemistry is concerned "the reform should take the direction of teaching the subject practically and with direct reference to its applications as every branch of chemistry in turn must necessarily be laid under contribution, chemists need have no fear that their field of action will be thereby unduly limited"

THE annual prize distribution and conversazione of the Northampton Institute Clerkenwell E C, was held on January 25 and 26 The prizes were distributed by Mr Evan Spicer, chairman of the London County Council, who in his address to the students made special mention of the importance of the engineering work which was being done at this institute, and of the unique character of the work in technical optics In regard to the latter he remarked that it had received the most sincere recognition of our Continental rivals inasmuch as work of a similar character was being started in France and Austria The principal in his report, referred to the present need of additional accommodation, notwithstanding the fact that the institute has this session occupied the buildings of the British Horological Institute for its technical optics work In the display of instruments made in the various laboratories on both evenings, there were several interesting items A wireless telephone system was made to work successfully across the courtyard, and some interesting experiments were shown with the electric arc used as a telephone receiver, and with the effect of light on selenium cells There was also an interesting display by the Postal Telegraph Department of some of the newest developments in telegraphy, both of the ordinary kind and wireless telegraphy, a complete De Forest set of the latter being at work The 75-ton testing machine and the 50-h p experimental engine were on view for the first time in the mechanical laboratories, and there was also a new 25-K V A alternator built in the institute with special modifications for experimental purposes, from which some interesting results may shortly be anticipated

A SCHEME for the organisation of a central lecture theatre for London, on the model of the Berlin "Urania," is being developed by a representative committee, which includes Sir William Ramsay, Sir W Huggins, and others A meeting was held last week under the presidency of Sir William Ramsay to hear an explanation of the scheme by Mr Albert Wollheim The chairman said he had given two lectures at the Berlin 'Urania' and was much struck with the crowds that visited the institution and constantly occupied themselves gaining knowledge of scientific facts Mr Wollheim explained that the statutes of the Berlin institution exclude the possibility of the undertaking being exploited commercially, all surplus profits, after the distribution of a 5 per cent maximum dividend, are devoted to the purchase of apparatus or to building extensions or carried to a reserve fund The proposed London "Urania" would not clash with the work of the learned societies but would promote their membership Illustrated popular lectures would be given on subjects of interest to the public in a building centrally situated and easily accessible In the summer months the "Urania" would be utilised as a centre for educational visits to museums, gardens of scientific societies, and so on An educational information bureau a library, and a publication department would be features of the institution It is interesting in this connection to recall a similar scheme for a civic museum recently outlined before the Sociological Society by Mr Huntly Carter It may be hoped that the promoters of these ideas will join hands and cooperate in providing London with a valuable adjunct to its existing educational facilities

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, December 20, 1906 —Lieut Col Prain F R S, vice-president, in the chair —*Exhibits* —Two specimens of albino woodlice *Oniscus asellus*, Linn W M **Webb**.—Photograph and dried specimens of *Fockea capensis* Endl a plant of considerable interest on account of its great rarity and its apparently great longevity N E **Brown**.—*Papers* —Report on the botanical collections made by Dr W A Cunnington in lakes Nyasa, Tanganyika and the Victoria Nyanza 1904-5 Dr A B **Rendle** Dr Cunnington spent about three weeks on and about Lake Nyasa, nearly nine months at Lake Tanganyika, and less than a fortnight on the west of the Victoria Nyanza His object was to make as complete a collection as possible of the plants and animals, especially from Lake Tanganyika with the view of solving the "Tanganyika problem" whether the fauna and flora of this lake indicate a former marine connection The flowering plants, fern allies, and Characeæ numbering about forty-five species, were for the most part, well-known and widely distributed forms such as *Najas marina*, species of Potamogeton *Pistia Stratiotes Ceratophyllum demersum, Myriophyllum spicatum, Jussiaea repens, Trapa natans* and *Chara zeylanica* with others restricted to tropical or subtropical Africa such as Ottelia *Boottia scabra*, and species of Utricularia In no case was there any suggestion of marine conditions either past or present, in the representatives of the flora

The plankton and fresh-water algæ, of which an account was given by Mr G S West, yielded remarkably rich results due partly, no doubt, to the paucity of our previous knowledge of the microscopic flora of these lakes, especially in the case of Tanganyika Mr West's list contains about 400 species, a large proportion of which are new, including one new genus of Palmellaceæ A few species from Tanganyika showed a striking affinity with marine forms, indicating that at some period the water of this lake had a considerable degree of salinity, but as Dr Cunnington explained, this did not involve a previous marine connection but might be explained by an increase in saline matter in the water due to the damming of the outlet from the lake This damming was perhaps a periodical occurrence, since Stanley, thirty years ago, described the lake as with no outlet, while a few years later Mr Hore, visiting the same spot as Stanley, found the water rushing through the present outlet towards the Congo —A new and abnormal species of Rhipicephalus W F **Cooper** and L E **Robinson.**

January 17 —Prof W A Herdman, F R S , president, in the chair —*Platanthera chlorantha*, Custor, var *tricalcarata* W Botting **Hemsley** The specimen had been found at Pax Sherborne, Dorset by Miss D R Wilson who sent it to Kew, the ten flowers on the spike were modified as described the paired sepals were spurred, and the lip was uppermost that is, the usual twist of the ovary was absent —Acanthaceæ of insular Malaya the late Mr C B **Clarke** This paper was complementary to a similar one, drawn up for the "Materials for a Flora of the Malay Peninsula" now in course of issue by Sir George King and Mr Gamble The paper includes in its area Malaya exclusive of the peninsula itself —An isopod, *Tachaea spongillicola* n sp of the family Corallanidæ, distinguished from its near ally, the marine *Tachaea crassipes* Schiodte and Meinert, by having the terminal joint of the maxillipeds, not smaller, but considerably larger than either of the two preceding joints Rev T R R **Stebbing** —A new British terrestrial isopod A **Patience.** The species in question, which Mr Patience has named *Trichoniscus Stebbingi*, n sp , was first obtained by him in a field near Alexandra Park, Glasgow in company with *T pygmaeus* Sars and *Trichoniscoides albidus* (Budde-Lund), and subsequently in some numbers in one of the propagating houses of the Glasgow Botanic Gardens

Society of Chemical Industry January 7 —Mr R J Friswell in the chair —The sixth International Congress of Applied Chemistry at Rome W F **Reid** (see NATURE vol lxxiv , p 65, May 17 1906) —The determination of higher alcohols in spirits, part 1, the "ester-iodine" method C H **Bedford** and R I **Jenks.** The authors point out the defects of the Allen-Marquardt process for the estimation of higher alcohols in potable spirits Dunstan and Dymond (*Pharm Journ* , 3 xix , 741) have shown how to determine organic nitrites by allowing them to act on an acid solution of potassium iodide in a flask void of oxygen and then titrating the liberated iodine with thiosulphate This serves as the basis of the authors' method Details are given for the extraction and esterification of the total higher alcohols, and the subsequent decomposition of the esters by iodine Beckmann's method of esterification (one part of sodium nitrite and two parts of acid potassium sulphate powdered together) is employed Results are given showing the accuracy of the method An analysis can easily be carried out in a day —The determination of indigotin in commercial indigo C **Bergtheil** and R V **Briggs** The authors criticise Bloxam's method for the determination of indigotin (Journ Soc Chem Ind , 1906, xxv , 735), and point out that low results are obtained The error is due to the factor on which the calculation is based and the loss of indigotin which invariably occurs in salting out and filtering the sulphonic acid salt A series of determinations was carried out by the authors' method (Journ Soc Chem Ind , 1906, xxv , 729) and by Bloxam's method (*loc cit*), and they are of opinion that the latter does not appear to be trustworthy either in application to pure indigotin or to commercial indigo The method is cumbersome and inapplicable to work in the indigo districts of India owing to the low temperature at which it is necessary to work, and the large amount of ice required for this purpose.

Geological Society, January 9 —Sir Archibald Geikie, Sec R S , president, in the chair —The Cretaceous formation of Bahia (Brazil) and the vertebrate fossils contained therein J **Mawson** and Dr A S **Woodward.** This paper relates to a series of estuarine and fresh-water deposits originally described to the Geological Society by the late Samuel Allport in 1859 The results of thirty years' collecting of fossils are summarised, and the distribution of the formation, so far as determined, is marked on a map The strata are disturbed by numerous dislocations and discordant dips, and no regular succession of zones or horizons can be discovered All the more important vertebrate fossils collected are now in the British Museum (Natural History) From these a few remains of new species are selected for special description A mandibular symphysis of a very large crocodile, with a long garial-like snout, belongs to one of the Goniopholidæ Some dinosaurian vertebræ seem to belong to the iguanodont group A large fish-skull represents a new genus allied to Macropoma, and indicates a species five or six times as large as any cœlacanth previously discovered The discussion of a complete list of the fossil Vertebrata proves that the formation is of Cretaceous age, and suggests that it may be Lower Cretaceous, as supposed by Hartt —A new dinosaurian reptile from the Trias of Lossiemouth, Elgin Dr A S **Woodward** Mr William Taylor of Elgin, recently discovered two skeletons of a small new reptile in the Triassic sandstone of Lossiemouth Two imperfect skeletons of the same species are also shown on a slab of the same sandstone in the British Museum (Natural History) The head and trunk measure only 4 inches in length, but there is a very long and slender tail The head is relatively large, and resembles that of Ornithosuchus in many respects but the fossils do not exhibit any teeth The author concludes that this must have been a running or leaping reptile, and that it represents a new genus of Dinosauria related to the American Triassic Hallopus

Faraday Society January 15 —Sir Joseph Swan, F R S , past-president in the chair —The application of the electron theory to electrolysis F E **Fournier d'Albe.** The electron theory, by postulating the existence of material carriers of all electric charges, is practically an extension of the ionic theory to solids and gases, and it thus brings into line the processes of metallic and electrolytic conduction The author directed attention to the importance of making further studies of mobility and quantitative determinations of the hydration of ions as a preliminary for determining the sizes of the ions and of their actual constitutions based on kinetic principles

Royal Meteorological Society, January 16 – Annual general meeting —Presidential address, weather in war time R **Bentley** The address showed how on more than three hundred occasions the course of history was greatly influenced by weather conditions

EDINBURGH

Royal Society, December 17, 1906 —Prof Gray, vice president, in the chair —The hæmo-renal salt index as a test of the functional efficiency of the kidney Dr Dawson **Turner** The hæmo-renal salt index is defined to be the ratio of the electrical resistance of the blood to the electrical resistance of the urine In health this ratio should be 4 or 5 When the index increases it indicates that the blood contains fewer salts or is richer in corpuscles, or that the urine contains more salts, or that all these changes exist together With low resistance of the urine the functional activity of the kidneys is increased Several medical cases were referred to, and it was pointed out that the method would probably prove to be of great value in surgery With the apparatus which had been devised the measurements could be rapidly made on very small quantities of both blood and urine The method was another example of the application of precise scientific measurement to clinical medicine and surgery, and showed the importance of a medical student being trained in medical experimental physics —Relation between magnetisation and electric conductivity in nickel at high temperatures Dr

C. G. Knott. The point of special interest was the manner in which the increase of conductance due to the application of a field transverse to the direction in which the conductivity was being measured first diminished steadily with rise of temperature until it reached a minimum at about 280° C, then rose abruptly to a maximum at 310° C, and finally fell off to zero at 350° C.—The relation between normal take-up or contraction and yarn-number for the same degree of twist in twisted threads: T. Oliver. In a former paper the relation between the take-up in the second twisting of a two-ply yarn and the amounts of first and second twistings was studied experimentally and analytically. The present paper considered the relation when, with the same twistings, different sizes of thread were used. This at once brings in the "yarn number," which cannot be taken in the same way as wires are gauged, but must depend on the relation of length to weight. Experimental results were obtained for two distinct sets of cases, according as the component threads were of the same diameter or of different diameters. Formulæ were established with which the experimental results were compared, and considering the complexities of the problem the comparison was sufficiently satisfactory.—The superposition of mechanical vibrations (electric oscillations) upon the magnetisation, and conversely, in iron, steel, and nickel, part ii: J. Russell. In this continuation of a difficult piece of work the author discussed the discrepancy between his former results and those obtained by Dr. Eccles, and expressed his opinion that the latter investigator had not taken sufficient precaution in reducing the metal to exactly the same magnetic state before each experiment. It is only by means of a succession of gradually diminishing reversals that we can be certain that the magnetised substance is brought back to a definite condition time after time.

January 7.—Prof. Crum Brown, vice-president, in the chair.—Notes on aboriginals of the northern territory of South Australia: Dr. W. Ramsay Smith. The paper contained a detailed discussion of several of the peculiar rites and customs of the Australian aborigines, such as the scars on shoulder, breast, arms and abdomen. Evidence was adduced that these scars had definite signification implying, perhaps, the number of children borne, the number still alive, the death of a near relative, or the widowhood of the individual bearing the scars. Other points taken up were the character of the dentition, the grasping power of the great toe, the rite of sub-incision, and the interpretation of the carved message sticks.—Exhibition of the skeletons of monkeys showing effects produced by improper feeding: Prof. D. J. Cunningham. The skeletons and skulls in the university anatomical museum frequently showed abnormalities, such as excessive bending or softening or a certain roughness on the surface. Many of the specimens had been purchased from travelling menageries, and there seemed to be little doubt that the effects were due to improper feeding and bad ventilation.—The partition of heat energy in the molecules of gases: Dr. P. Ehrenfest.—Vibrating systems which are not subject to the Maxwell-Boltmann law. Second paper: Dr. Wm. Peddie. These two papers were sequels to Dr. Peddie's first paper, certain results in which were criticised and to some extent modified. Dr. Peddie also gave a purely mathematical discussion of the problem in distribution devised by Lord Kelvin as a test-case for the proof or disproof of the Boltzmann-Maxwell doctrine. This was the problem of the motion of a particle within a circular region the rim of which consisted of a series of semi-circular corrugations. Although in the long run the time integral of the kinetic energy of the component motion parallel to any fixed direction would in this case be the same for all directions, the time integrals of the two components, radial and transversal, according to polar coordinates, would not be the same, thus disproving the Boltzmann-Maxwell law.—Note on cases of contour zones of molecular arrangement from surface disturbance: Dr. James Hunter. When a piece of fine-grained stone which has been used for polishing splits, an inspection of the new surfaces shows a distinct zone running approximately parallel to the cylindrical surface of the stone disc. Outward towards the circumference, the texture of the stone is radial, suggesting radial arrangements of the molecules, while inside there is no trace of this arrangement. Similar contours appear in other cases, such as when glass is cut by a diamond or by the cutting-wheel. It was interesting to observe how different the patterns of the markings were in these two instances.

PARIS

Academy of Sciences, January 21.—M. Henri Becquerel in the chair.—A proposed system of classification for the bibliography of subjects bearing on seismology: G. Bigourdan.—An expedition of Commandant Chaves in Africa: Prince Albert I of Monaco. An outline of the magnetic work done on this expedition, and an account of the comparison of the instruments used with those at Cape Town.—The resistance and elastic equilibrium of tubes round which an elastic wire is wound: A. Jacob.—Communications were received from M. Milan Stefanik and M. Janssen stating that observations of the solar eclipse of January 14 had been prevented by clouds.—The approximation of functions by limited trigonometrical series: Maurice Fréchet.—Helices of propulsion: P. Tsoucalas and J. Vlahavas.—Propulsive helices: F. Ferrier.—Measurements of the Zeeman effect on the blue lines of zinc: P. Weiss and A. Cotton. The lines studied were the three 4810.71, 4722.26 and 4680.33, in a magnetic field the strength of which varied between 25,500 and 36,000 Gauss. Contrary to the results of Reese and Kent, the distance between the two magnetic components was found to be proportional to the intensity of the field, the results being in complete accord with the simple relations which Runge and Paschen have discovered.—The modifications which the absorption bands of tysonite undergo in a magnetic field: Jean Becquerel.—The preparation of pure helium by filtration of gases from cleveite through a wall of silica: Adrien Jaquerod and L. Louis Perrot. In a previous paper the authors have shown that the helium thermometer with a fused quartz bulb was useless on account of the readiness with which the gas penetrated the walls at a high temperature. On the other hand, it was found that silica is quite impermeable to all other gases at about 1000° C., with the exception of hydrogen and possibly carbon monoxide. In the present paper application is made of these facts to the preparation of pure helium from cleveite. Using a bulb of 42 c.c. capacity the method described gives a yield of about 1 c.c. of pure helium per hour. The gas obtained in this way was found by spectroscopic examination to be free from nitrogen, the only gas present besides helium being a minute trace of hydrogen, possibly derived from the electrodes of the tube.—The absence of nutrition in the formation of the artificial plants of Leduc: MM. Charrin and Goupil. Experiments are described showing that the word nutrition is misapplied when used in connection with these phenomena.—The mechanism of the synthesis of some quinoline derivatives: L. J. Simon.—The conditions of stability of the carbamines: H. Guillemard.—The synthesis of derivatives of cyclohexane: 3.3-dimethyl- and 3.3.6-trimethyl-cyclohexanones: G. Blanc. The author has described in an earlier paper the synthetical preparation of $\beta\beta$-dimethyl- and $\beta\beta\epsilon$-trimethyl-pimelic acids. These acids are converted into the corresponding anhydrides by treatment with acetic anhydride, and these, slowly distilled under ordinary atmospheric pressure, split up quantitatively into carbon dioxide and the cyclohexanone.—The synthesis of natural erythrite: M. Lespieau. The preparation of an inactive erythrolactone has been described in an earlier paper; this lactone treated with brucine and the product submitted to fractional crystallisation, has yielded a lævorotatory lactone and natural erythrite.—The symbiosis of the fig and blastophage: Leclerc du Sablon.—The presence of formaldehyde in green plants: G. Kimpflin. As a reagent for detecting formaldehyde, the author uses methylpara-amidometa-cresol, and shows that the reaction is distinctive. This reagent has the advantage that it does not destroy vegetable tissue.—The active substances of *Tephrosia Vogelii*: M. Hanriot. By methods given in detail the author has isolated a volatile liquid, tephrosal, of the composition $C_{16}H_{14}O$, and a crystalline substance, tephrosine, of the formula $C_{31}H_{26}O_{10}$.—The formation and distribution of an

essential oil in a living plant Eug **Charabot** and G **Laloue.** An examination of the plant *Artemisia absynthium* —The pharmacodynamical action of a new alkaloid contained in the root of fresh valerian J **Chevalier.**—The formation of the skeleton in some of the hexacorals Armand **Krempf** —The part belonging to the anastomotic branch of the spinal in the physiological properties of the pneumo-gastric or pneumo-spinal nerve F X Lesbre and F **Maignon** —Some new experiments concerning the pathology of pulmonary anthracosis G **Kuss** and E **Lobstein.** Further experiments bearing on the criticisms of MM Calmette, Grysez, and Vansteenberghe The conclusions drawn from this work are that ordinary pulmonary anthracosis as arising in ordinary life, is produced by inhalation and not by deglutition —The evolution of the Cerithidæ in the Middle and Upper Eocene of the Paris basin Jean **Boussac.**

GÖTTINGEN

Royal Society of Sciences —The *Nachrichten* (physico-mathematical section) parts iii and iv for 1906, contains the following memoirs communicated to the society —

ANATOMY OF THE HORSE

(1) *Surgical Anatomy of the Horse* Part I By John T Share-Jones Pp xii+159, with 33 plates (London Williams and Norgate, 1906)

(2) *Le Cheval* By H-J Gobert Pp viii+412, with 80 figures (Paris Baillière et Fils, 1907) Price 7 francs

(1) SINCE 1832, when William Percival produced the first work exclusively devoted to the anatomy of the horse, considerable advances have been made in the methods of teaching veterinary anatomy, but it cannot be said that the production of anatomical literature has been correspondingly abundant in this country The veterinarian has not had his time too heavily taxed by the examination of frequent new publications Consequently, he will welcome with all the more interest the first part of a "Surgical Anatomy of the Horse," from the pen of Mr J T Share-Jones, of the Liverpool Veterinary School The present volume deals with the anatomy of the head and neck as applied to the surgery of these regions, and it is to be followed by further parts devoted, in like manner, to the rest of the body

The author, while admitting the psychological value of anatomy as a means of developing the faculty of observation, "is impelled to the conclusion that the subject is primarily and fundamentally utilitarian, and that the teaching of it should always be in association with the subject of surgery" Such an expression of opinion leads to the conclusion that the author is a surgeon at heart, and not an anatomist as the term is generally understood nowadays The modern anatomist has become much more a student of the scientific and comparative side of his subject than of its surgical or—to quote the author—utilitarian aspect Surgery occupying the first place in his affections, and anatomy coming second, Mr Share-Jones is clearly the proper person to write a "Surgical Anatomy" But even a surgeon, in producing such a work, should bear in mind that "anatomy" is the substantive, and "surgical" not more than an adjective The work before us is rather more surgical and much less anatomical than are most standard publications bearing the same title The various operations performed on the regions discussed are described at some length, with the consequent curtailment of the space allotted to topography The result is not satisfactory from an anatomical point of view for it means that the descriptions, as given, are of only moderate value to the student or practitioner to whom the structures have been made familiar by dissection, and of less value to the student entering upon a course of practical anatomy

Certain statements, moreover, are of doubtful clarity and accuracy For example, in speaking of the rudimentary first premolar teeth of the horse (referred to as "wolf's teeth") it is said that "each is developed in the same dental groove as the corresponding row of molars, and is probably due to the displacement of a supernumerary dental germ in the groove" This scarcely squares with phylogeny Again, the short section on the development of the teeth might have been omitted with profit, for from it the reader will gather little accurate knowledge of the process To justify this assertion we may quote the first part of the section "The first stage in the development of a tooth is the appearance in a groove in one of the maxillary bones of a little closed sac, which is called the dental follicle The membranous wall of the follicle encloses a papilla, which is at a later stage termed the dental pulp, and from which the dentine is secreted The enamel is developed from a special layer of epithelium which covers the upper aspect of the pulp and which is called the enamel organ As the dentine is formed from the superficial cells of the pulp, it becomes deposited between the latter and the follicular wall From the superficial cells the tubular processes of the dentine are thrown out, but the intertubular substance is secreted by the deeper layer of cells This latter substance contains the earthy salts"

The prefatory statement that "an endeavour has been made to illustrate graphically wherever possible, and to reduce the written matter to a minimum" leads to a close examination of the illustrations Of these it may be said that they are of unequal merit, and few of them will compare favourably with illustrations in Continental works on topographical anatomy In Plate xii we notice a rather glaring inaccuracy in regard to the teeth, which leads us to suspect that the drawing was not made from an actual section It is not stated at what level the section was supposed to have been made and it is therefore not easy to form a correct judgment of its truth to nature, but surely there is something wrong with the mylo-hyoid and digastricus muscles?

That, in spite of the blemishes to which we have referred the work will fill a gap in veterinary literature is undoubted, inasmuch as there is no other book in the English language which claims to be a surgical anatomy of the horse That it will be of service to the student and practitioner may also be taken for granted The publisher and printer deserve praise for the manner in which they have turned out the book

(2) M Gobert has endeavoured, with a considerable measure of success to provide a short popular treatise on the organisation maintenance in health and utilisation of the horse for the use of those who desire to possess a greater knowledge of the animal than can be acquired through the more customary channels From the nature and scope of the book, it is not expected that the section which deals with the anatomy of the horse will be other than extremely elementary For the same reason it is unnecessary to submit it to elaborate criticism The section has many merits Its facts are set forth in clear terms shorn, as far as possible, of technicalities At the same time the author has fallen into the error so frequently made by writers of similar popular works,

of including details which cannot possibly be thoroughly understood by the ordinary lay reader For example, a certain amount of description of microscopic structure is included, which is either too much or too little It would probably have been better omitted entirely Again, a short list of muscles, such as is given on p 14, cannot be of any value whatever to the reader for whom the book is intended Most of the illustrations are good, but some of them—notably Fig 2—are far from clear

The compilation has much to commend it, and at the same time has many of the defects which appear to be inseparable from books of its kind

HIGHER EDUCATION IN GERMANY

The German Universities and University Study By Friedrich Paulsen Authorised translation by Frank Thilly and William Elwang Pp xvi+451 (London Longmans, Green and Co, 1906) Price 15s net

THIS excellent translation of Prof Paulsen's celebrated book on the German universities will be welcomed by many readers interested in the question of university education who have not the time or opportunity to read it in the original, the book is not merely an account of German universities but treats the general subject of higher education in its relation to the advancement of knowledge and to the life of the community on a broad and philosophic basis

The peculiar value which seems to us to attach to this work is due to this very breadth of view the author is concerned, not with pressing the importance of some particular aspect of university life or of the claims of a particular branch of learning, an attitude which reduces so much of the writing on English education to mere sectional pamphleteering, but with the presentation of the historical development of university life, and especially with the function of the university under modern conditions, and with the problems which these conditions bring in their train It is probably true that it is easier to be dispassionate when one is contented, and Prof Paulsen is, on the whole, contented with the German universities and what they have done and are doing for the culture of the German people, but his contentment goes deeper, he is satisfied that the universities in Germany owe their hold over the intellectual life of the people to their unreserved acceptation of the scientific spirit, that is to say, the spirit of inquiry and free investigation into all the departments of learning The university is defended and vindicated by the author primarily as an institution for research and the advancement of knowledge, and secondarily as a place of education, secondarily, not from the mistaken notion that education is considered less important than the expansion of the limits of knowledge, for we may remember that the only way of entering the learned professions, including schoolmastering and the Civil Service, in Germany is through the university, but because the most important part of a university education is considered to be the actual contact with the fountains of knowledge and the acquisition of a capacity to grapple with original sources and to form an independent opinion The system undoubtedly has its dangers, especially the danger of over-specialisation and the fault of encouraging students to undertake scientific investigation who would be more fittingly employed in practical affairs, but the author considers that the universities have gained and retained their influence by standing in the van of new ideas as the home for investigation, instead of handing on traditional learning, tardily and painfully modified from without by the changes of the times

It is interesting to note the parting of the ways between the French and German universities at the beginning of the nineteenth century, the Napoleonic era converted the French universities into technical schools for the professions and banished the pursuit of learning to the academies, while at that very time Humboldt founded the modern University of Berlin in direct opposition as an institution of free learning and broad education, and to that ideal all the German universities conformed

There can hardly be any doubt as to which ideal has proved most fruitful, but the plan is apparently now advocated in some quarters in Germany of attempting to combine the technical schools in a closer alliance with the universities, and Prof Paulsen has sufficient faith in the innate Teutonic love of learning to believe that science would not thereby be strangled in the grasp of a short-sighted utilitarianism This, of course especially applies to the natural sciences, but in all the faculties there have grown up side by side with the universities, technical academies of art, military science, commerce, jurisprudence, and the like, which train an increasing number of students

"All public institutions of learning," remarks Prof Paulsen, "are called into existence by social needs" and it is interesting to follow the historical evolution of the university from this point of view as it is skilfully delineated by the author The mediæval universities seem really to have satisfied our modern ideals to an extent which is perhaps not commonly suspected, and will probably never be re-attained, they were, in the first place, cosmopolitan, and not under the restrictions of a particular country or Government, and they were the true repositories of the learning of their times With the coming of the Renaissance, and later of the Reformation, a change of the greatest importance occurred, from being cosmopolitan they became strictly territorial, from being free they became the *instrumenta dominationis* of the particular Government under which they happened to be

In consequence, the faculty of law was chiefly fostered to the detriment of all others, and towards the end of the seventeenth century in Germany university life was at a very low ebb With the foundations of Halle and Gottingen in the eighteenth

century a revival began, which Prof Paulsen traces largely to the rise of the philosophical faculty from servitude as *ancilla theologiae* to the leadership, though it doubtless corresponded with the awakening of the general intellectual life of the country inaugurated by Klopstock and Lessing

But the old freedom of the universities in Germany was necessarily never revived in its completion, and the position of the university as a State institution dependent to a large degree in its internal administration on the Government of the country in which it is situated leads to anomalies even now which Englishmen will not readily understand, though the real interference with freedom may be less than it seems Thus the government of the university, even extending to the syllabus of studies in a particular faculty, is potentially, and sometimes actually, under the control of a Minister of Education, while the ordinary professors are appointed by the Sovereign of their country and the extraordinary by the Minister of Education, and it appears from the statistics quoted by Prof Paulsen that in a fair proportion of cases the appointment runs counter to the recommendation of the faculties, but our author, ever determined to see both sides of a question, remarks that political and Court intrigues tend to efface the back-stairs politics of the faculties, so that in the end the right man is usually chosen

It follows also from the dependency of the universities on the State that the teachers must hold cautious political views, and even Prof Paulsen has nothing at all to say in favour of the Prussian Ministry which dismissed a privatdocent of physics from his post on the sole ground that he was a social democrat

To choose one more point from a book absorbing throughout in interest, it is instructive to note that the absence of all social life such as is enjoyed at the old English universities does not cause that complete satisfaction which opponents of the system are so keen to insist on, but in several instances boarding-houses are being instituted where students can live in common In the Middle Ages the residential collegiate system was of course universal, and a few colleges were retained long after the system had died out on the Continent for the benefit of the poorer students It can hardly be held that the collegiate system persisted in England for the same purpose

We may sketch the plan of Prof Paulsen's work as follows —in the first book we are given an outline of the historical development of the universities from the Middle Ages down to modern times, and probably nowhere else can so much be learnt on this subject within the compass of about seventy pages the succeeding books are concerned with present-day conditions, the second treating of the relation of the university to the State, to society, and to the Church the third dealing with university teachers and the methods of instruction, the fourth with university life from the student's point of view In the fifth book some special problems connected with the several faculties of theology law, medicine, and philosophy are discussed G S

GEODESY IN THE SCHOOLS

Text-Book on Geodesy and Least Squares Prepared for the Use of Civil Engineering Students By Prof Charles L Crandall Pp x+329 (New York John Wiley and Sons, London Chapman and Hall, Ltd , 1907) Price 12s 6d net

SUCH a treatise offers little scope for originality of treatment or of design The problems connected with triangulation, or with measurement, or with levelling have been considered too frequently and too minutely by experts to permit the introduction of novelty Similarly in the application of the results of measurement to the discussion of the figure of the earth, the author must follow beaten paths and occupy ground that has been thoroughly surveyed His opportunity for exhibiting independence lies rather in the judicious selection of materials, and particularly in determining what should be omitted, that is to say, in considering the requirements of those for whom he is writing Prof Crandall is addressing himself primarily to students of Cornell University, and presumably to those who are beginning the study of the subject and not to professional men engaged in actual work

For a text-book to be used by beginners it might be objected that the author has a little overlaid his treatise with a superfluity of detail The increased attention given in university training to the study of geodesical problems and the determination of the coordinates of a station on the earth's surface is a feature that should be welcomed and encouraged On many grounds it may be urged that the use of instruments in the field is an admirable training, more especially as it affords opportunities for the application of those formulæ which have been acquired from bookwork For this reason one could defend the somewhat lengthy description of instruments here given, their adjustment and method of use, the determination of corrections, &c though at times the author is tempted to indulge in too great detail This error, if it be an error, arises from following too closely the reports and data furnished from the offices of the Coast Survey The danger to be feared is that the minute care and attention to detail necessary in operations extending over a large area, may tend to make the subject repellent to a student whose main object is to gain an intelligent insight into the processes involved But a greater fault appears to be one of omission There is too little, almost nothing concerning the methods of deriving the latitude and longitude of a station And surely such matters are of quite equal importance with the measurement of a base line, and fall as decidedly within the compass of such a work To be able to determine one's position on the earth involves something more practical than a mere college exercise It is information that is frequently needed and may become a matter of great importance

The first few chapters of the book are mainly occupied with the description of the use and adjustment of instruments in the field The next three are devoted to consideration of problems connected with

the figure of the Earth. The mathematical ingenuity exhibited may be interesting, but is familiar. In the form and to the extent in which the several problems are discussed, these chapters scarcely belong to a practical treatise, and do not afford the means of applying the facts that the student has himself derived from the use of instruments.

In the second part, which consists of three chapters, the author serves up the standing dish of least squares. So far as theory is concerned he has followed Chauvenet, and for the practical application to triangulation and conditioned problems the admirable treatise of Wright and Hayford on "The Adjustment of Observations" (see NATURE, vol. lxxiv., p. 148). The book is well illustrated, and there are some useful tables and information given in an appendix, though we scarcely understand the principles upon which the formulæ have been selected. The information throughout is conveyed in a clear and lucid manner, but a little unevenness is sometimes noticeable, as though the author were uncertain of the degree of thoroughness with which the several topics should be treated.

AN AMERICAN TEXT-BOOK OF ENTOMOLOGY.

Entomology, with Special Reference to its Biological and Economic Aspects. By Dr. J. W. Folsom. Pp. vi+485; illustrated. (London: Rebman, Ltd., 1906.) Price 14s. net.

A WORK treating of entomology purely from the bionomic and economic standpoints is a distinct and long-felt want, but it cannot be said that the book under review supplies that want adequately, in spite of its title and a statement in the preface that it "was written in an effort to meet a growing demand for a biological treatment of entomology."

With such admirable and detailed manuals of insect anatomy as Packard's "Text-book of Entomology" and Henneguy's "Les Insectes" already in the field, Dr. Folsom could have safely avoided a treatment of this subject, as it is, his second chapter, entitled "Anatomy and Physiology," occupies nearly one-third of the book, and yet fails to attain the comprehensiveness of the aforementioned manuals. Chapter vii., on the origin of adaptations and of species, might well have been omitted, for it contains nothing that is new and little that is not almost common knowledge; curiously enough, though de Vries's work is discussed, there is no mention of Mendel or his followers.

The inevitable result of these two unnecessary chapters is an unfortunate brevity of treatment in the more useful and interesting sections of the book, and many important phenomena and facts are crowded out altogether. The author may claim (as he does) that his work is "concise," but hardly that it is "comprehensive," since there is no mention of the life-history of Mantidæ, of the eggs of Phasmidæ, of fig-insects, of the cuckoo-spit, of the formation of stick-lac, of the remarkable symbiosis of Acari and bees of the genus Koptorthosoma, of the extraordinary beetles Mormolyce and Hypocephalus. The accounts of parthenogenesis, of phosphorescent insects, and of aquatic insects are lamentably brief, and nothing at all is said of the insects found in caves.

Chapter ix., on insects in relation to other animals, is one of the best in the book; Dr. S. A. Forbes's admirable reports on the insect food of birds and fishes have been largely drawn upon, and deserve the attention directed to them. We have not noticed many errors, but the following need correction in a later edition:—Paraponyx is not the only lepidopterous genus with truly aquatic larvæ (p. 184); *parakleta* should be *paralekta* (p. 216); it is at least doubtful if the mimicry of bees and wasps by species of the genus Volucella can be classed under the heading of aggressive mimicry, it is far more probable that the flies secure immunity from the attacks of vertebrate foes by their resemblance to stinging insects than that this resemblance enables them to enter unobserved the nests of hosts who are quick enough to resist the intrusion of strangers of their own species (p. 235); the blood-parasite conveyed by *Glossina morsitans* is not similar to the malarial parasite (p. 306). The tsetse-fly is cited as the carrier of the blood-parasite in nagana disease, but not of the organism causing sleeping sickness. In the anatomical chapter some reference should be made to the fact that the stomodæal and proctodæal sections of the alimentary canal are lined with chitin, whilst the mesenteron, being of endodermal origin, is not.

The numerous text figures are for the most part excellent, and a goodly proportion are original; special attention may be directed to Figs. 242 and 260, the latter, if a genuine record of an actual occurrence, is a triumph of nature-photography. Fig. 244, illustrating protective mimicry, is unfortunate, for it represents *Eristalis tenax* mimicking a stingless drone-bee. The coloured frontispiece is not only a poor example of what can be done in these days of improved methods of chromolithography and three-colour photography, but also abounds in errors, e.g. Fig. 1, labelled *Heliconius eucrate*, is *Lycorea halia*; Fig. 4 is not *Mechanitis lysimnia*, but *Melinaea ethra*; Fig. 5 is not *Papilio merope* ♂ from South Africa, but *Papilio antinorii* ♀ from Abyssinia; Fig. 8 is *Amauris echeria* from West Africa, not from South Africa; Fig. 10 is not really like any butterfly known to science, but it apparently represents *Papilio merope*, ♀ form *cenea*, though it is labelled *Amauris echeria*, the "model" of the Papilio mimic; Fig. 11, labelled *Papilio merope* ♀, is apparently *P. echerioides* ♀. This gives a total of six errors in eleven figures! It is evident that the author has reproduced the errors occurring in the plates illustrating Weismann's "Evolution Theory," and it is a pity that, in the case of the African butterflies at any rate, he did not consult Trimen's classical paper or the frontispiece to Poulton's "Colours of Animals."

A useful bibliography and a trustworthy and comprehensive index conclude the work. R. S.

OUR BOOK SHELF

Minerals and Metals a Reference-book [of] Useful Data and Tables of Information A condensed compilation from various sources by J G Goesel Pp xiii+287 (New York John Wiley and Sons, London Chapman and Hall, Ltd, 1906) Price 12*s* 6*d* net

THE scope of this pocket-book of reference may be best indicated by quoting from the title-page — "Legal, customary, and scientific measurements, geological classification, rock composition, chemistry dry and wet assay, mineralogy, metallurgy, metal founding and plating, hydraulics, water purification; mineral oils, gases, explosives, strength of materials, including woods, their properties, adaptability, and preservation, pigments, gums, and solvents for paints and varnishes, miscellaneous data and receipts" It will thus be seen that the variety of subjects treated is much more extensive than is indicated by the main title, "Minerals and Metals", in fact there is, in a handy form, a vast amount of information which may be of use to mining engineers and others

Books of this kind should, of course, be free from ambiguities and errors, but in the portions which we have specially tested, namely those dealing with minerals and precious stones numerous errors have been detected, quite extraordinary chemical formulæ are given for even common minerals whilst in the spelling of names there are many misprints

The book is clearly printed though not on thin paper, and is well bound in limp leather with rounded corners and gilt edges

Practical Exercises in Chemistry By G C Donington, Senior Science Master in the Leeds Grammar School Pp x+251 (London Macmillan and Co Ltd, 1906) Price 2s 6*d*

MR DONINGTON'S little book derives special interest from the fact that whilst he is a pupil, and a very grateful one, of Prof Armstrong, he has found himself compelled by experience as a science master in a school (and one in which no specially unfavourable conditions prevail) to depart from the practice of leaving the pupils without a text book during their practical lessons This experience is we believe by no means uncommon and it is an advantage that the "felt want" should be supplied by one who naturally strives to conserve as much as he can of the merits of the no text-book system In this object the author has, we think, had good success and his book is likely to take high rank among those which of late years have been written to set forth an elementary course of chemistry for those secondary schools where there is a desire to teach scientific method through the medium of this science

Paradoxes of Nature and Science By Dr W Hampson Pp xv+304 (London Cassell and Co Ltd, 1906) Price 6s

DR HAMPSON proposes to explain to the uninitiated certain scientific "paradoxes" The only possible "explanation" of such paradoxes is attained by showing that the abnormal phenomena are determined by precisely the same laws as the normal phenomena, to "explain" why a balloon rises it is necessary to propound the general principles of gravitational mechanics and to show that it rises for the same reason as a stone falls But Dr Hampson eschews general principles His "explanations" are appeals to prejudices as unscientific as those which gave rise to the appearance of a paradox Even when his arguments are sound they must convey to a reader a wholly untrue idea of scientific method

But they are not always sound Sometimes he wanders far out of his depth, as, for instance, when he seeks to solve the old logical contradiction of Achilles and the tortoise by a reference to the atomic structure of matter He would have done well to restrain his jeers at mathematicians until he had gained some acquaintance with the elements of their science

Seasonal Botany, a Supplementary Text-book By M O'Brien Harris Pp 56 (London Blackie and Son, Ltd, 1906) Price 8*d*

PROBABLY most teaching botanists looking back upon their early experiences when they first found it necessary to draft a syllabus of instruction can recall an attempt to prepare a course adapted to the round of the seasons In the case of pure observational study such a course is profitable but it is the general experience that a seasonal adjustment does not accord with the best morphological or physiological sequence, and this opinion is not modified by the arguments or scheme put forward in the present instance

The seasonal syllabus given in the form of a tabulated scheme, and a number of physiological experiments on very usual lines form the chief contents of the book

French Readings in Science Selections from Scientific and Technical Writers arranged and edited for the Use of Students By de V Payen-Payne Pp vii+230 (London Blackie and Son, Ltd, 1906) Price 3s 6*d*

IGNORANCE of either French or German is a serious handicap to the scientific worker University examining bodies are recognising this need and some such as the University of London demand from candidates for science degrees a knowledge of these languages sufficient to enable them to translate with fair ease and accuracy In making his selection of passages from scientific treatises Mr de Payen-Payne has included some extracts for their modernity and others because of their association with great names in science The compiler is catholic in his tastes and his work should provide students with just the practice they require

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Radium and Geology

THOSE interested in this subject should refer to the paper which appears in the last issue of the *Philosophical Magazine* by Mr A S Eve on the ionisation of the atmosphere over the ocean Mr Eve cites observations and adds others of his own, showing that the ionisation over the ocean is much the same as over the land and points out the difficulty of explaining this in view of the small content of radium in sea-water compared with that in ordinary rocks Possessed as I am with the view that extra terrestrial radio-active dust reaching the earth may account for much of the radium of soils sediments and rocks I cannot but think that Mr Eve's difficulty may find explanation in an extra terrestrial source of supply

Mr Eve also gives some new determinations of the radium in sea water and arrives at results which considerably accentuate the discrepancy which I referred to

in my letter written on January 6 (NATURE, January 24, p 294) On his results a normal river supply of the supposed uranium would in 90,000 years suffice to give the ocean its present radio-activity In short, practically the whole of the uranium has to be accounted for in the sediments Mr Eve perceived the difficulty, and suggests that the sediments are, indeed, its destination I have already referred to the difficulties attending this view

Prof Sollas's contention (p 319) as to the probable original character of the uranium in zircon is, I think, unanswerable I had this fully in view when referring to uranium-bearing minerals in certain rocks In certain rock masses the zircon might be the chief or entire source of radium, but it would appear that this cannot possibly be the case with ordinary granites The analysis made by Mr Strutt of a Cornish granite showed that less than one-ninth only could in this case be so accounted for Mr Strutt directs attention to this Again, Prof Sollas shows by the analysis he cites that this granite was probably unusually rich in zircon In Mr Clarke's last report of analytical work done in the laboratory of the United States Geological Survey (Bulletin No 228) I have found nine granites in which the zirconia is determined The highest percentage was 0 08, and the others ranged from 0 04 downwards to a trace Mr Clarke in Bulletin No 148 speaking of zircon says of igneous rocks generally —"It may rarely be present up to a few tenths of 1 per cent of the rock" He also gives as roughly approximate that the average content of zirconia in igneous rocks is 0 03 This would imply a quantity of zircon adequate to account for barely 4 per cent of the mean radium content of igneous rocks

There are probably other radio-active minerals possessing an original store of uranium but I think Mr Strutt has shown good reason for believing that the chief radium carrier is the mica at least in granites This is a mineral which from its properties would be very likely to absorb and retain substances in solution J JOLY

Trinity College Dublin

The Green Tints of Sunset

THE appearance of a green light at sunset like many other phenomena supposed to have only recently attracted attention, was noticed and commented upon by the ancient Egyptians, and more particularly so because in the clear air of Egypt the tints of sunset are peculiarly distinct

As the sun there descends nearer and nearer to the horizon apparently hastening to disappear behind one of the Libyan hills, as if burying itself in the sand at their base the immensely enlarged flaming disc suddenly becomes for an instant, of a brilliant green colour, and immediately a series of green rays suffuses the sky in many directions well-nigh to the zenith

The same phenomenon appears sometimes at sunrise, but to a smaller extent

According to ancient Egyptian notions of cosmogony, the sun after passing through the western gate into the world of night travelled northward parallel to the Nile until the sixth hour when it commenced to journey southward, having passed to the eastern side of Egypt, and, finally at sunrise came forth by the "Gate of the East"

Now during the nocturnal voyage the solar orb was said to be a disc of Mafkait, which was the title of a green-coloured mineral, and so the sun was considered from sunset to sunrise to be coloured green Sometimes just as the last part of the sun's disc vanishes, its colour changes from green to blue, and so also after it has disappeared the sky near the horizon is often green whilst toward the zenith it is blue This was alluded to in ancient Egyptian writings where sometimes it is said that at sunrise or sunset the sun's rays were of Tehen, a blue metal the title of which is often used in reference to the blue of the sky

In Egyptian thought day was the emblem of life and night that of death and the nocturnal sun being identified with Osiris thus rendered Osiris the god of the dead The setting sun being green therefore Osiris as the nocturnal deity of the dead, was on the monuments and representations of him when referred to as god of the dead painted green, as were other funerary divinities, such as Sekar, the form of the dead Ptah, which was that of a mummy with face and hands coloured green or dark blue. The splendid coffins of the high priests of Ammon, all the decorative tableaus of which are painted, frequently depict the green sun, and deities such as Anubis, god of the funerary journey, Isis, Nephtys, and Osiris are coloured green

It may be interesting, if possible, to decide whether the Egyptians recorded their observation of the green colour at sunset in very early times The late M Groff, who has treated upon this point in the *Bulletin de l'Institut Egyptien*, proved that they did so as early as the fifth dynasty, by showing that a monument of that date delineates the half disc of the setting sun by a figure painted in three successive bands, the two lower, that is to say, those abutting on the horizon—of green, and the upper one of blue

This is not the proper place to discuss the innumerable instances upon Egyptian relics of representations relative to death being coloured green It is undoubtedly the case that the practice arose from the green tints of sunset and sunrise, but it may justifiably be said that in the green-coloured sun disc referred to, which dates 5000 years back, we have the, at present, earliest known human record of an astronomical phenomenon JOSEPH OFFORD

2 Fairfax Road, Bedford Park W, January 29

February and March Meteors.

FEBRUARY and March meteoric showers have never been sufficiently investigated No very special displays have invited abundant observation and, moreover, cold and cloudy weather often prevails at this season Meteors, too, are generally rare, and from these several causes few observers have made persevering efforts to determine the strengths and positions of the radiants visible

In 1877 and 1887, February-March, the writer at Bristol obtained some observations, but they were altogether insufficient to reveal more than a small minority of the meteoric streams of this period Giuseppe Zezioli at Bergamo and Lieut-Colonel G L Tupman in the Mediterranean in 1867 71 effected many valuable observations in February and March, and perhaps their results are the best secured up to the present time

With the earth approaching aphelion, meteors are usually scarce, though there are a number of interesting showers visible and fire-balls are invitingly plentiful But the firmament not having been thoroughly watched during the latter part of the winter season an earnest, persevering and accurate observer has a very promising field before him and may expect to discover more new showers than are likely to reward his vigils under summer and autumnal skies

A number of streams presented during February and March have been already detected but there is a large majority of very feeble systems still awaiting recognition The visible strengths of many showers vary from year to year and there are periodical displays which only occur at long intervals, so that fresh observations are very desirable if our knowledge is to keep pace with the developments frequently occurring

Fireballs are often numerous on about February 10 and March 1–4 Some of the radiant points of ordinary shooting stars recorded at Bristol are —

Bristol February 4 W F DENNING

THE DAWN OF MODERN GEOGRAPHY.[1]

MR. C. R. BEAZLEY has now published the third and concluding volume of his important work, "The Dawn of Modern Geography." The third volume is "A History of Exploration and Geographical Science from the Middle of the Thirteenth to the Early Years of the Fifteenth Century (c. A.D. 1260–1420)." A summary of the further progress of geographical knowledge through the time of Prince Henry the Navigator until the rounding of the Cape of Good Hope by Bartholomeu Dias and the voyage of Vasco da Gama at the end of the fifteenth century is appended.

Mr. Beazley's work stops short, therefore, with the voyages of Prince Henry's seamen, with which the dawn of modern geography may well be said to have ripened into full morning. He begins this volume

Genoese Map of the Black Sea. A.D. 1300–5. From "The Dawn of Modern Geography."

with the Polos, and they and Friar Odoric are the central figures of the book. Naturally the narrative tends to group itself around persons, and to become a mere summarised account of their doings; there is little scope for hypothesis or argument except in respect to disputed names and sites. The central facts of the period described are the sea voyages of the Italian sailors, Venetians and Genoese, and the land-journeys of the merchants of the two great republics. Mr. Beazley shows how the sea-enterprise of the Spaniards and Portuguese was started and at first directed by Genoese shipmen, and how knowledge of the Further East was increased by the competition of the *mercatori* of the Ligurian Commonwealth and the City of the Lagoons (which, by the way, he insists on spelling "Lagunes").

Next in importance is the contribution of the Roman Church. Mr. Beazley well emphasises the great importance of the Roman attempt to proselytise the East during the period of Moslem eclipse by the pagan Tartar power. Already, in the preceding period, of which Mr. Beazley's second volume treated, the tendency towards an alliance of Christendom with Heathenesse against the Saracens had come into prominence. The idea of crushing the followers of the False Prophet between the hammer of the Hun and the Frankish anvil had seemed by no means an impossible one. Nor had it seemed unlikely that, with the help of the hordes of Gog and Magog which God had sent forth to do His will, the defeat of the Horns of Hattin might be avenged and the Holy Places restored to Christendom, and why should not the Tartars themselves enter the Christian fold? So Rome sent forth missionaries to the lands of the Ilkhan, and Western bishoprics arose where hitherto only the heretical Armenians, Jacobites, and Nestorians had maintained a faith of doubtful authenticity amid Moslems and Heathen, and the Greek had not been seen for centuries.

Yet of all this endeavour only one tangible result remained: the increased knowledge of the East which the missionaries transmitted to the West. Mutual doubt born of ignorance, mutual incompatibility, prevented Hun and Frank from understanding one another; the precariousness of the way from West to East made communication difficult, and the divisions of the Papacy led the Tartars to place little faith in the power of Christendom to strike anew from the West. Also, a new spirit had arisen in the world; the merchant had come to power side by side with king, knight, and priest. The ideals of the twelfth

century were out of date to the men of the thirteenth, especially in the Mediterranean lands, where a republic of merchants had deposed an Emperor and parcelled out his lands, using the cry of the Faith as a cloak for their own ambition. And now neither the merchants of Venice nor those of Genoa would give up their *fondaci* of Alexandria or Cairo, and their lucrative trade with the land of the Soldan, the head-centre of Islâm, at the bidding of a Sanuto in order to restore Jerusalem to the temporal dominion of their faith. The days of the Crusaders were over, the Viking spirit from the North that had impelled the warriors of the Cross to set out to battle with the Paynim followers of Mahound was exhausted, and the men of the later day seemed to love the bezant as much as they venerated the Rood. So the Western Tartars turned to Mohammedanism, the light of the Roman missions in the lands of the Ilkhanate flickered and died out, and the only result of this second phase in the intercourse between the Frankish West and the East was the increased geographical knowledge which in conjunction with the commercial ventures of the time, it brought about. Many ran to and fro, and knowledge was increased.

Many ran far in those days. A journey to Cathay in the thirteenth century must have seemed almost as tremendous as a voyage to the moon would now, and the stories which the travellers brought back of the Chinese must have seemed almost as incredible to their stay-at-home friends as stories of Selenites. Mr. Beazley describes the journeys of the Polos at length, and gives a most interesting epitome of Messer Marco's description of the land of the Great Cham Kublai. The civilised power, in comparison with which Europe was a den of savages, the posts, the banknotes, the great seaport of Zayton (Arabic *Zêtûn*, the modern Amoy), the enormous city of Hangchau, the mighty Khanbalik or Peking, Coleridge's *Xanadu*, the city of Kublai Khan himself, the distant isles of Zipangu or Japan, all must have sounded incredibly wonderful to the Western ear. Yet that the *Milioni* were not liars was proved by many a witness contemporary and following shortly after, Monte Corvino the first Roman Archbishop of Peking, Odoric the Friar, Marignolli the Bishop of Bisignano, and many a simple Genoese trader besides. Of all these Odoric is the most interesting, and seems to have gone furthest. For if Marco Polo visited Szechuen, Yunnan and Burma in his official capacity as a Chinese *Futai* and was the first to acquaint Europe with these regions, the humble missionary brought back knowledge of the Philippines and of the isles beyond Borneo, and was the first European to visit Lhasa. His description, too, of Cathay is second in interest to that of Polo only. And few things in this description are more interesting than his account of how he with the Bishop and other missionaries met the Great Khan (a successor of Kublai) upon the high road and went forth to meet him, the Bishop in cope and mitre, with cross upraised on high, all singing the *Veni Creator*, and how the Emperor raised himself in his palanquin reverently to kiss the sign of salvation, and how Brother Odoric, mindful of the injunction *Non apparebis in conspectu meo vacuus*, tendered to Majesty his humble trencher of apples, whereof the Emperor took one and deigned to eat it.

The Tartar Emperors of the Yuen always treated the Frank Christians with courtesy and showed interest in their religion; it was not until the national Chinese uprising and their replacement by the Ming that Christianity was oppressed, and, very shortly, China was shut to them as completely as two hundred years later Japan was shut to Christian endeavour by the policy of the Tokugawa Shoguns. Just as the Nearer East was barred by the conversion of the Persian Tartars to Islâm, so was the Further East barred by the accession of a national dynasty to the throne of China. No more Franks visited China until the coming of the ships of Portugal and Holland in the sixteenth century. Here also the progress of geographical knowledge was brought to a halt and the promise of the dawn, temporarily at least, belied.

In the opposite field of operations, however, progress, though slower, was never stayed. As was natural, on account of the then superior state of their civilisation to that of the Franks, the Maghrabi Mohammedans were the first to explore the coasts beyond the Pillars of Hercules, and even discovered Madeira and the Canaries. This we know from the voyage of the Eight *Maghrûrîn*, or "Deceived Ones," of Lisbon then (before 1147 A.D., on p. 411 Mr. Beazley says 1154 A.D.) a Moslem city. These worthies set forth in a manner strongly reminiscent of the Wise Men of Gotham, who went to Sea in a Bowl, and found Madeira, which they called, not "Al Ghanam" (as Mr. Beazley has it in his note on p. 532: this would mean "the Sheep"), but *Gezîret al-Ghanam*, "The Isle of Sheep." Afterwards they found the Canaries and eventually got back to Lisbon, where the stay-at-home Gothamites mocked at them for "Maghrûrîn," and probably for *Majnûnîn*, "lunatics," also. However, their isles existed, and in the thirteenth century the Canaries were discovered by the Genoese Lancelot Malocello, from whom Lanzarote took its name.

Mr. Beazley describes the gradual progress of knowledge of these Western isles, the discovery of Madeira by Portuguese under Genoese admiralty, the voyages of Portuguese Catalans, and French beyond Cap Nun to Bojador, and the French expeditions of Béthencourt and Gadifer de la Salle to the Canaries at the end of the fourteenth century which perhaps are the origin of the unsubstantiated French claim to have discovered Guinea long before the sailors of Prince Henry the Navigator. Mr. Beazley is not indistinctly of opinion that the claim of the seventeenth-century writer de Bellefond that Dieppois sailors (we object to Mr. Beazley's "Dieppese") traded with the Guinea coast as early as 1364 is unfounded, to say the least of it. He does not enter much into the question of the MS. of "Mr. William Carter" describing these voyages, which, according to M. Margry, in his "Navigations françaises d'après les documents inédits" (Paris, 1867), was lent to M. de Rosny in 1852 or 1853, and has not since been traced. "Mr. William Carter" is a Frenchman's name for a typical Englishman; it savours of "Miss Mary Smith" or the British "M. Jules Dupont" for a Frenchman. But it should not be difficult to ascertain whether there existed sixty years ago a gentleman bearing this name who would have been likely to have possessed such a manuscript. In any case, however, even if found, it would probably turn out to be of seventeenth-century date, and as worthless for history as de Bellefond's own testimony or the ridiculous rubbish of the Zeni (pp. 456–60) about their "voyages" to the North, in which these heroes confuse Friesland with Iceland, and bestow upon "Frisland" a king called "Zichmni," and so on.

Mr. Beazley gives an interesting sketch of Genoese maritime activity, and shows that the Genoese were the founders of map-making with their wonderfully accurate *portolani*, of which he gives several illustrations, all of them extremely good with the one exception of that of the "Veschonte" map of 1311 (p. 513), which is marred by an ugly band stretched

across it, one would have thought that this could have been avoided

Of English contributors to earth-knowledge at this time there were very few The wonderful Oxford philosopher, Roger Bacon (to whom Alma Mater ought to put up a statue) certainly knew more about the world than most of us are accustomed to think was known in his time, and was remarkably up to date in his information (pp 500–507), but there were no others like him, nor were any of our sailors or chapmen discoverers like the men of Genoa or Venice They were pirates who could gain victories over "Espagnols-sur-mer," but no more Maundeville, alas, is now well known to be a fraud He never existed but in the perverse brain of a Liégois clerk, John à-Beard, who concocted his tales of "Anthropophagi, and men with heads beneath their shoulders," from the true stories of contemporary travellers and many an antick tale drest up anew The supposed English "discovery" of Madeira about 1370 by Machin is probably a myth (p 441) Edward I 's embassy to the Ilkhan Arghun of Persia in 1291–3 under Geoffrey of Langley (Galfridus de Langele) is interesting, but the ambassador went under Genoese guidance, and the English were out of their element in those parts A century later an English constable of Guisnes and his secretary took a jaunt to Egypt and the Holy Places, and were no doubt grievously fleeced by the "magnus" and the "alius drugemannus," and the usual crowd of guides, donkey-boys, and camel-drivers and other demanders of *bakhshish*, much as their descendants might now be But they saw a giraffe, and no doubt that was worth the money The trip cost each pilgrim about 250*l* in modern value Such tours were not uncommon at the time Mr Beazley mentions some Germans; an active knight who ran out to Jerusalem and back in less than the space of one year, and another, William of Boldensel, who travelled in great state, and was so mighty and great that none dared trouble him for impost or dues of any kind wherever he went There was also that amusing pedant the Rector of Sudheim, who consorted with none but kings and nobles the whole time he was away, and when he got back no doubt bored the good folk of his Westphalian village to death with them for the rest of his life

Another German, Schiltberger was no Boldensel or Ludolf, he consorted with kings, it is true, but as their slave Captured at Nicopolis, he was the bondman of Bajazet the Turk, and was by the fortune of battle transferred to the servitude of Timur the Tartar Only after many years of slavery did he escape to his native Germany again His account of the lands in which he lived so many years, from Egypt to Siberia, is naturally of the greatest value, we wish only that he had told us more He was but an unlettered warrior

Of the rule of the second Tartar Empire we have further knowledge from an unexpected source Of Catalan mercantile activity we have already spoken The Castilian rivals of Aragon were no traders, and their first contribution to geographical knowledge was due to an embassy to the East like that of the Englishman Langley, but more than a century after his time In 1403 King Henry of Castille dispatched the noble hidalgo Don Ruy Gonzalez de Clavijo as his envoy to Timur the Tartar, Tamerlane the Great himself and Mr Beazley tells us of the terrible journey of the Spanish envoys, across the uninhabited wastes which the terrible tyrant had made, to his court at Samarkand, of what they saw when at last they got there, and how they left on their return shortly before the conqueror set out on his endeavour to rival Genghis and conquer China, only to die a few stages out of his capital (1405)

In Spain at this time the Moslem kingdom of Granada still existed, shorn of its ancient glory both in war and in science But Moslems still contributed to the increase of geographical knowledge, and one, from the neighbouring Morocco, was second to none as a traveller and recorder of his travels This was the wonderful Shêkh Ibn Batûta of Fez, who in the fourteenth century traversed the greater part of the known world, from Peking to Timbuktu, and wrote an account of his travels which, as might indeed have been expected, shows far greater intelligence than most Frankish records of his time We wish that Mr Beazley had written more about the Moslem geographers Yakut is dismissed in three lines (p 534), Edrisi, in spite of his relations with the Franks of Sicily, has but two pages It is not enough

Space forbids further account of the interesting things in Mr Beazley's last volume In it there are singularly few misprints, and the author has evidently submitted his Oriental names to the scrutiny of someone familiar with Arabic and Syriac We have no more "Jesus Jabuses" or "Mar Jabalabas" in this volume though "Nujmuddin" for the name of an Egyptian sultan is hardly pretty, let us give this Star of the Faith" his hard Egyptian *gim*, and call him Nigm-ud-din

The long-needed index has appeared in the last volume, and with its completion let us cordially congratulate Mr Beazley on the achievement of his work, which is a credit both to him and to his University

SIR MICHAEL FOSTER, K C B, F R S

FIFTY years ago the science of physiology, as now understood was scarcely recognised It began in England when the early anatomists added an account of the uses or actions of the several muscles, glands, and viscera to the account of their form and structure So in the sixteenth and seventeenth centuries each anatomical description was followed by the word *Usus* True, experiments were practised from the time of Vesalius downward, by Harvey himself, by Redi, and by the Rev Stephen Hales and often with brilliant success The problems of the circulation of spontaneous generation and of blood-pressure in the arteries were solved by these admirable experimenters, but their efforts were isolated Fifty years ago we had in England excellent observers with the microscope, particularly Sharpey and Bowman, but there was no systematic study of the working of the human machine by masters like Johannes Muller, Ludwig and Claude Bernard, and "practical physiology" consisted in little more than examining the tissues under the microscope and exhibiting a few chemical reactions of animal fluids

The first attempt to teach the new physiology in England is due to Dr Gamgee, who translated the fifth edition of Hermann's famous text-book About the same time a scientific physician in London gave up practice for the sake of investigating healthy and morbid functions of plants and animals as well as man, and a few years later a young country surgeon who had already given hostages to fortune by a wife and two children persuaded his father to let him leave Huntingdon and adopt the fortunes of a teacher of physiology Dr Burdon-Sanderson from Edinburgh, and Dr Michael Foster from Huntingdon, taught the one pathology (human animal and vegetable) the other histology and "the use of the microscope" Both were tall in stature and striking

in appearance, both made their mark in the practical application of biology to the health of men and animals, both migrated from University College, London, Sanderson to Oxford, and Foster to Cambridge, in order to introduce the modern science of biology into the curriculum of the older universities, Sanderson died somewhat earlier, Foster has only just been removed.

It is still too early to decide on the extent and permanent value of Foster's work, but some estimate of it may be attempted.

His strongest point was force of character, energy, perseverance, thoroughness. He expected his pupils to work as hard as he did, and to regard scientific investigation as the most honourable and delightful pursuit. He had the rare faculty of discovering talent in pupils and giving it concentration and method. He set them problems to solve, and as soon as they had shown their capacity to work alone, he left them to plant the seed in another virgin soil. Foster's success at Cambridge was remarkable, both in the number of those who took up serious study in the laboratory and in the great eminence achieved by very many. His greatest merit is that, like Ludwig, he created in his disciples the noble ambition to increase knowledge, and was content to see the result and to applaud. Some of his pupils have made themselves a European reputation, others have carried Foster's methods and enthusiasm into botany, pathology, public health, and medicine.

Foster early acquired an excellent style for scientific writing. Probably Huxley's lectures and writings pleased him first, but however Foster's style was acquired, he at last attained the state which Hazlitt asserted (not without reason) he had reached when it was less trouble to write well than to write ill.

The child's "lessons" in physiology were as well composed and expressed as the famous "text-book" (1876) and the "History of Physiology" (1900).[1]

He soon gathered together his first band of disciples, among them Francis Balfour, whose brilliant career was sadly ended by an accident on the Alps, Langley, who succeeded him at Cambridge, Gaskell, Sherrington, Adam Sedgwick, L. E. Shore, F. G. Hopkins—these are only some of the names of men who owed their first step in scientific investigation to Foster's inspiration, and remained his cordial friends to the last.

As soon as he had taught the elements of practical research in physiology he encouraged his pupils to work out their own vein, whether the task first set them was completely finished or not. Whatever other academical differences he encountered, Foster never failed in the support of his old pupils.

Apart from his lectures and his books Foster threw himself heartily into the duties which his position as secretary of the Royal Society entailed. He held the office from 1881 to 1903 under the presidency of Spottiswoode, Huxley, Stokes, Kelvin, Lister, and Huggins. He did much to stimulate interest in the biological side of the society.

Foster was a well-known official of the British Association, and was president at Dover in 1897, when he was made a K.C.B. He spoke only to begin or reinforce the discussion. On the council his influence was powerful, and was never used for private ends. At the annual dinner of the society Foster only spoke at intervals, and the task was always well performed. But his oratory at its best was to be heard at less formal meetings where ready wit and good-natured sallies were appropriate.

After his connection with Cambridge was severed, Foster found fresh occasion for serving science by his election as representative of the University of London in Parliament in succession to Sir John Lubbock, now Lord Avebury. His speeches in the House were few, and chiefly confined to subjects on which he could speak with authority—education, public health, fisheries, scientific experiments on animals, and similar cases of applied knowledge. He spoke slowly and distinctly, with a quiet emphasis which secured attention from both sides of the House. He entered Parliament as a Unionist and a supporter of the Boer War, but he found himself out of sympathy with Mr. Balfour's Government on financial policy and on popular education, he therefore sought first to resign, and afterwards to transfer his seat from the Unionist to the Liberal side. At the General Election he was defeated by a very small majority, and his seat is occupied by Sir Philip Magnus. In connection with his political career must be mentioned the important commissions on which Foster served—that on vaccination, of which the late Lord Herschell was chairman, that on the disposal of sewage, another on fisheries, and, perhaps the most important, one on tuberculosis in animals and man. The final report of this committee was signed by Foster only a few days before his death.

On the day before he was taken ill, at the meeting of the British Science Guild at the Mansion House, he spoke as follows:—"This meeting shows how widely science is entering into our lives, it has interwoven itself with our works, and is more and more guiding our ways. If we could imagine a world without science, we might address to that world the words which Dante addressed to Italy in the Middle Ages. 'Nave senza nocchiero in gran tempesta.' Nothing is more clear than that science is not for men of science alone. We, with our slight efforts, can lift great weights. We are a feeble folk, and if we can effect anything it is by pulling the long end of the lever, and it is because of the length of the lever that we are able to effect anything. Thus, with our slight efforts we can lift great weights at present, and we shall lift heavier and heavier weights in the future if we have the support of the people and the support of the Government bidden by the people. It is for the people to bid the Government, and the present Government perhaps above all other Governments, to help science, for they can give us the opportunities we are asking for to-day."

To Foster's personal charm no description can do justice. To old friends like Prof. Carey Foster or Mr. Coots Trotter he was always the same. On a dredging expedition where he and his mate managed the tackle in the intervals of sea-sickness, in a crowded Italian railway carriage or receiving polyglot professors Foster's voice always announced good humour, good temper, and good nature.

He delighted in his garden, and was said to cultivate physiology when not too busy with a new iris. Next to his own species he delighted in cats and dogs and flying birds. His early life between Huntingdon and Cambridge was one of struggle and his later days, when he had lost his laboratory, were clouded by occasional ill-health, but, on the whole, his strenuous and active life was a happy one, for it exercised his great and varied abilities for worthy objects. He was a man greatly beloved, and he has left a deep memorial in the hearts of all who knew him best.

The funeral of Sir Michael Foster took place at Huntingdon on Saturday, among those present at the graveside being Lady Foster, Dr. Michael G. Foster, Dr. R. Bradford, Sir Thomas Barlow, Dr. Pye Smith, Mr. Horace Darwin, Dr. Gaskell, Prof. Langley and Prof. Sherrington. A memorial service was held on Saturday afternoon at St. James's Church, Piccadilly, and was attended

[1] Even Foster's writings were not always free from oversights. In one passage he advises the reader to "get a firm hold of the most prominent feature of the subject", in another he corrects a woodcut by explaining that the granules "have been rendered too bold by the artist."

by many leading men of science The Royal Society, of which Sir Michael Foster was a secretary for twenty-two years, was represented by Lord Rayleigh, O M, president, Prof D Ferrier, vice-president, Sir Archibald Geikie, secretary, Mr R Harrison, assistant secretary, and a large number of fellows of the society Among those present were Lord Reay (president of the British Academy), Lord Monkswell, Sir William Crookes Sir Philip Magnus, M P, Sir Arthur Rucker (principal of the University of London) and Lady Rucker, Sir Norman and Lady Lockyer (British Science Guild), Major MacMahon (British Association), Sir William Ramsay, Sir Joseph Swan, Sir J Crichton-Browne, Sir James Blyth Prof R Meldola (president of the Chemical Society), Dr Russell Wells, Prof S P Thompson, Dr E Divers, Dr J Kingston Fowler (dean of the faculty of medicine at the University of London), Prof Wyndham Dunstan, Prof Tilden, Prof Priebsch, Sir Alexander Pedler, Dr Bashford, Prof Thane, Prof Starling, Dr Hugo Muller, Prof Emerson Reynolds, Sir Henry Howorth, Prof McLeod, Sir H Trueman Wood, Dr Horace Brown, Prof Judd Prof Hull, and Mr Frederick Macmillan

A large and representative congregation also attended the memorial service held in Trinity College Chapel, Cambridge, of which college Sir Michael was a fellow The congregation included the Vice-Chancellor (the Rev F S Roberts, Master of Caius), Profs Sir R S Ball E C Clark, T Clifford Allbutt A Macalister, A R Forsyth Carey Foster F Howard Marsh, G Sims Woodhead H Jackson, and A C Seward, Dr W N Shaw and the following representatives of learned societies —University of Oxford, Prof Poulton Dr Collier Prof Gotch, the Royal Society, Mr A B Kempe (treasurer) Mr F Darwin (foreign secretary) and other councillors University College, London, Prof H S Foxwell, British Association, Sir George Darwin and Mr A E Shipley, Cambridge Philosophical Society, Dr Hobson (president) and Mr H F Newall (treasurer) the Epidemiological Society of London, Dr H Timbrell Bulstrode Manchester University, Prof Lamb and Prof Conway

NOTES

AT the forthcoming meeting of the British Association in Leicester, the evening lectures will be by Mr W Duddell, on "The Arc and the Spark in Radio-telegraphy" and by Dr F A Dixey on "Recent Developments in the Theory of Mimicry" The lecture to the operative classes will be given by Prof H A Miers, F R S, on "The Growth of a Crystal"

WE notice with deep regret that Prof D I Mendeléeff, the eminent Russian chemist who was born seventy three years ago to-day, died on February 2 Prof Mendeléeff was the subject of a "Scientific Worthy" article in NATURE of June 27, 1889 (vol xl p 193) and we hope to supplement this next week with a short account of work accomplished by him since that date

WE learn from the *British Medical Journal* that the seventh International Congress of Physiology will be held this year at Heidelberg on August 13–16, under the presidency of Prof August Kossel In connection with the congress there will be an exhibition of scientific apparatus Announcements of communications should be sent to the Physiological Institute, Heidelberg, before June 15

A REUTER message from Melbourne on January 31 reports that slight shocks of earthquake have occurred at Eden, New South Wales, and at Gabo Island, off the coast of Victoria Severe shocks were felt in north-eastern Tasmania on January 30 News has reached Melbourne that two severe and prolonged shocks were felt in the Tonga Islands on January 2

Science announces that Dr Otto Lummer, professor of experimental physics at Breslau, will begin a course of ten lectures at Columbia University on February 15 Prof J Larmor, Sec R S, will begin a course of six lectures on March 27 Mr W Bateson, F R S, will give the Silliman memorial lectures at Yale University next year The preceding lecturers on this foundation have been Prof J J Thomson, F R S Prof C S Sherrington, F R S, Prof Ernest Rutherford, F R S, and Prof W Nernst

ON Tuesday next February 12 Prof W Stirling will begin a course of six lectures at the Royal Institution on "The Visual Apparatus of Man and Animals" on Thursday, February 14, Mr A Harker will give the first of two lectures on "The Minute Structures of Igneous Rocks and their Significance", and on Saturday, February 16, Prof J J Thomson will commence a course of six lectures on "Rontgen, Kathode and Positive Rays" The Friday evening discourse on February 15 will be by Mr J J Lister on "Foraminifera"

A COMMITTEE has been appointed by the Board of Treasury to inquire generally into the work now performed at the National Physical Laboratory with special reference to the character of the tests undertaken there and the lines on which any further development of the work of the laboratory should proceed The committee consists of Mr G W Balfour chairman Sir Andrew Noble Bart K C B, F R S Sir J Wolfe Barry K C B F R S Mr W J Crossley M P, and Mr R Chalmers C B Mr G C Upcott of the Treasury will act as secretary to the committee

UPON the authority of the *Figaro* the Paris correspondant of the *Times* reports that M Daniel Osiris has left by his will a sum of one million sterling to the Pasteur Institute The bequest by which the Pasteur Institute thus benefits will provide it with an annual income of from 30 000*l* to 40 000*l* It is already one of the best endowed scientific institutions in the world, and this princely gift will enable it to organise on a practical basis a large number of new branch establishments for scientific research all over France and in the French colonies

COLONEL JOHN MERCER BROOKE whose death in his eightieth year was recently announced was best known as the inventor of a deep sea sounding apparatus which was subsequently superseded by that of Lord Kelvin During the American Civil War, Colonel Brooke, along with Maury, the distinguished hydrographer, associated himself with the seceding States, and was successful in effecting many improvements in the cannon of the time At the close of the war he was appointed a professor in the Virginia Military Institute at Lexington, and held the chair of physics and astronomy until 1899 In the years preceding the Civil War, he was engaged in making hydrographic surveys in the Pacific Ocean, particularly in the archipelago and along the coasts of China and Japan

A RECENT Reuter message from Entebbe shows that the new Commissioner of Uganda is making vigorous efforts to combat the scourge of sleeping sickness Acting upon the discoveries made by the Royal Society's commission with regard to the transmission of the disease by the local species of tsetse-fly, it is sought to render the fly innocuous by preventing it from becoming infected with the micro-organism (Trypanosoma) which causes the disease With this end in view the natives are being removed from the

lake shore, the region which is the special haunt of the tsetse fly in question while at the lake ports, such as Entebbe and Jinja, every effort is being made to oust the fly by destroying the vegetation which harbours it and Entebbe is already reported to be clear of fly It is only to be hoped that the process of deforestation will be carried out with discretion as well as with zeal, and only those tracts denuded of forest which have been definitely proved to harbour the tsetse, a forest tree may be destroyed in half an hour which a hundred years will not replace The experience of other diseases transmitted by biting insects such as yellow fever, indicates that the most efficient method of preventing the spread of the disease is to isolate the patients in such a way as to prevent them from infecting the insects which are the carriers If it is possible to carry this out on so large a scale as the Protectorate Government is trying to do it, we may hope to see in a few years the disease stamped out completely in the territory of Uganda The Commissioner is to be congratulated on the promptness and energy with which he is turning the conclusions of scientific investigation to practical use

AN interesting innovation in coal-mining practice is reported from the United States where at a colliery at Shamokin Pennsylvania concrete has been substituted for mine timbering A plant for the manufacture of these cement props is in course of erection at Trevorton

ON January 28 coal was struck at Lord Dudley's sinkings at Baggeridge Woods at a depth of 556 yards The seam is 20 feet thick, and beds of excellent ironstone have also been encountered The discovery has verified the prediction of geologists regarding the existence of Coal measures under the sandstone to the west of the South Staffordshire coalfield This is the first place where coal has been found on the eastern side of the great Western Boundary fault, and the discovery is one of national importance The work of sinking was commenced nine years ago and great difficulties had to be contended with in consequence of the large quantities of water encountered

THE Transvaal Geological Survey has issued a monograph (Memoir No 3, Pretoria, 1906 price 7s 6d) by Mr E T Mellor, on the geology of the Transvaal Coal measures, with special reference to the Witbank coal field It contains a detailed account of the coal resources of the Witbank district at the present time the most important coalfield in the Transvaal In addition the available information regarding the geology of the Coal measures of the Transvaal in general is ably summarised Notes on the correlation of the Transvaal Coal-measures a list of the fossils of the Transvaal Coal-measures analyses of the coals statistics of production from 1893 to 1906 and a useful bibliography are appended The memoir covers sixty pages and is accompanied by a map, six sections, and fourteen plates reproduced from photographs

IN the *Engineer* of February 1 there is a copiously illustrated description of the Tehuantepec railway and of the terminal harbours at Salina Cruz, on the Pacific, and *Coatzacoalcos*, on the Gulf of Mexico, which were formally opened by the President of the Republic of Mexico on January 23 The length of the line is 189 miles, and the opening up of a trade route across the isthmus will be of special benefit to the middle west of the United States The average saving in distance by the Tehuantepec route over a Panama canal for traffic between Europe or the Atlantic ports of the United States is about 1250 miles Proposals to construct a railway across the isthmus were made as long ago as 1842, and a railway was completed by 1894, the Mexican Government having spent on the undertaking 3 500,000*l* The railway, however, was not adapted for heavy traffic, and had no terminal facilities or harbour works In 1898 the Government entered into a contract with the London firm of S. Pearson and Son, Ltd , to reconstruct the line and to provide harbour accommodation This has now been done at a cost of 9,500,000*l* and the railway will undoubtedly prove a formidable competitor to the Panama Canal when that difficult enterprise is completed For the Panama Canal the Americans have decided on a lock-canal system , but this system cannot Mr P Bunau Varilla points out in a very important paper contributed to the Society of Arts (Journal vol lv , p 239), be looked forward to with complacency in a volcanic neighbourhood subject to earthquakes Mr Bunau-Varilla who had been connected with the Panama Canal since 1884, proposes a well-considered alternative scheme in which water is used as the carrying power for the machinery to do the excavating and for the transport of the dredged material In short, the heavy rainfall is not treated as an enemy, but converted into a friend and ally In this way Mr Bunau-Varilla claims to have solved the problem set by Charles V in 1523 to Cortes Discover the secret of the straits (*el Secreto del Estrecho*) The secret lies in the topography and hydraulics of the isthmus Everything has been prepared by nature, in the high valley of the Chagres, to lift the earth that obstructs the site of the straits Harness this power and the straits will be made by its spontaneous action

IN a document issued by the Public Works Department, the director of the Zoological Gardens at Giza announces that he has returned from a trip to the Sudan, bringing with him a number of animals, inclusive of a giraffe, three young elephants, and five ril gazelles (*Gazella ruficollis*)

HAVING in earlier issues of the same journal discussed the filtering apparatus attached to the gill-rakers of various groups of surface fishes especially those which feed on plankton Dr Enoch Zander in part ii of vol lxxxv of the *Zeitschrift für wissenschaftliche Zoologie* records the results of his investigations in connection with corresponding structures in deep-sea fishes The general results arrived at in the case of surface-dwelling species hold good in the main for deep-sea fishes, forms living in open water usually having the filtering apparatus much more strongly developed than in the bottom-dwelling types The large-headed open water genus Stomias is, however, an exception in this respect

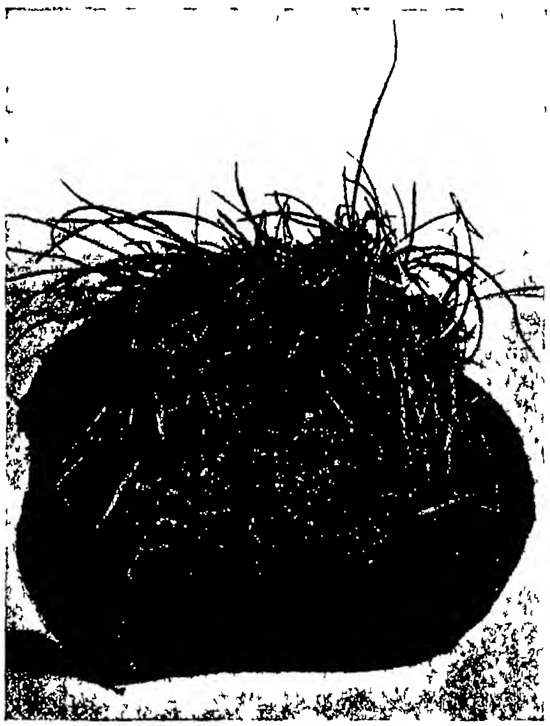
IN the *American Naturalist* for January Mr E Linton describes the manner in which the parasitic fish *Fierasfer affinis* effects an entrance into the body of the sea-cucumber which serves as its host Although the observations are not entirely new, they are of considerable interest When the small pellucid fish comes alongside of the holothurian it gradually feels its way down the body of the latter by means of its head until it reaches the vent, when it immediately curls itself into a loop and thrusts the tip of its whip-like tail into the aperture of the latter When this is accomplished, the fish straightens its body and proceeds leisurely to insinuate itself tail-first, into the body of its host, the action being apparently assisted by the spines of the dorsal and ventral fins The whole process occupies only about half a minute

MUCH interest attaches to an account, by Mr James Murray, in the January number of the *Zoologist*, of a remarkable "encystment" undergone by a British species of so-called "water-bear" (Macrobiotus). Certain peculiar little yellow elliptical or sausage-shaped packages, from which, when squeezed, water-bears in a quiescent condition spurted out, were, it appears, first observed. Subsequent investigation proved these to be an early stage of the encystment of these creatures. In the species fully examined there is an outer cyst with six rudimentary legs; inside this is an inner, limbless cyst containing at first a fully developed water-bear. Later on the Macrobiotus shrinks to an almost amorphous condition, so that it looks more like a worm. What happens afterwards and likewise the object of these strange changes have yet to be ascertained. A similar encystment was detected almost synchronously by Prof. Lauterborn in the case of a Continental species. In the same issue Mr. A. Campbell describes certain naked house-mice similar to a type described in 1856 as *Mus musculus nudoplicatus*. Since, however, this phase is a pathological development, it has obviously no right to a racial name.

THE U.S. Bureau of Entomology has re-issued (Bulletin No. 26) a report, published in 1895, on the San José or Chinese scale-insect (*Aspidiotus perniciosus*) in a revised and expanded form, so as to include an account of the investigations and remedial measures which have been undertaken and suggested since that date. The author of the new publication is Mr. C. L. Marlatt, acting chief of the Bureau. The insect, it seems, first made its appearance in America in the early seventies at San José, California, on the estate of the late Mr. James Lick, who was in the habit of importing plants from abroad. It was not, however, until 1901, as the result of a special expedition, that its native home was definitely located in north-eastern China. The isolated condition of this habitat is considered to be the reason that prevented the pest from overrunning a large portion of the world centuries ago. Despite the destruction caused to orchards when it once obtains a footing, the pest is now to a great extent under control, mainly owing to a lime-sulphur wash. In some degree the invasion has, indeed, been a blessing in disguise, since the greater care rendered necessary in selection, planting, and culture has largely benefited fruit-growing in general. At one time great hopes were entertained that a Chinese ladybird would form the most efficient restraining agent, but the use of washes and the presence of a parasite were inimical to the beetle.

WE have to acknowledge the receipt of the first three parts of a new publication from the Museum für Natur- und Heimatkunde zu Magdeburg, edited by Prof. A. Mertens, the director of the museum. By far the most important item in these *Abhandlungen und Berichte* is a paper by the editor on the urus or aurochs (*Bos primigenius*), which occupies the whole of part ii. The author gives a review and digest of the whole of the early literature and documents relating to the ancient wild ox of Europe, as well as of the comments upon them by previous writers. In his opinion, there is no doubt that the name aurochs properly belongs to this animal, although it has often been misapplied to the bison. It is likewise certain that in the time of Herberstain (the middle of the sixteenth century) both aurochs and bison were living in Poland, and that they were seen alive by him. According to other testimony, there was living in the Jaktorowka (or Wiskitki) forest, of the Masovia district of Poland, in the year 1564 a herd of thirty aurochs. By 1599 the number was reduced to twenty-four, while in 1602 only four remained, these being reduced in 1620 to a single cow, which appears to have been alive seven years later. It seems, however, that a few half-domesticated individuals were living in captivity in 1627. Herberstain's testimony that the aurochs was typically a black (or at all events a very dark-coloured) animal with a light dorsal streak is accepted. Other evidence tends, however, to show that there was a grey variety or phase in Poland, and a red one in central Germany, while the partially domesticated individuals kept in confinement during the early part of the seventeenth century may have developed other colour phases with partial albinism. Several particulars with regard to the breeding and general habits of the aurochs are also given.

IN a fifth instalment of his "Studies of Mexican and Central American Plants," published as vol. x., part iii., of the Contributions from the United States National Herbarium, Dr. J. N. Rose describes a large number of new species. The author being greatly interested in cacti, made them the subject of special investigation during his trip in 1905, and has identified several new and interesting specimens that are described and illustrated. In some cases numerous individuals cluster together to form a large cushion, as *Echinocactus robustus*; others develop into strange arboreal structures producing hundreds of nearly erect branches, notably *Cereus Webberi*, while *Echinocactus ingens* produces a large circular body that is cut up into sections resembling Dutch cheeses and boiled with sugar to make candy. Even more curious is the liliaceous plant shown in the illustration here reproduced, that is characterised by its thick corky exterior, and lives upon the food absorbed through a few fibrous roots; it forms the type of a new genus named after Shakespeare's Caliban, *Calibanus caespitosus*.



Calibanus caespitosus (Scheidw.) Rose.

IN the Journal of the Royal Microscopical Society for December, 1906, Dr. Alfred C. Stokes contributes a note on a certain form of butterfly scale the structure of which well illustrates certain points in connection with the much-studied "Podura" scale. He says:—"These special wing-scales are formed of three distinct membranes, of which the upper and the lower bear longitudinal ribs, between which both membranes are distinctly, even conspicuously, perforated by minute apertures arranged in rows more or less horizontal." It appears not to be generally known that the "clouded yellow" (*Colias edusa*) possesses pear-shaped wing-scales mixed with the ordinary scales, corresponding more or less closely to Dr. Stokes's description. These special scales seem to take the place of the "plumules" of many Pieridæ and Satyridæ, and of the "battledore" scales of Lycænidæ.

THE growth of the sudd on the Upper Nile and the blocking of American rivers with plants of the water fern, Azolla, are well-known examples of the danger arising out of the undue development of certain water weeds. The most recent instance is recorded from Australia, where the water hyacinth, *Pontederia* (*Eichhornia*) *crassipes*, characterised by its bladder-like swollen petioles and attractive blue flowers, has, owing to its rapid propagation by means of offsets, become a nuisance in the northern rivers of New South Wales and in Queensland. A report prepared by the order of the Minister for Public Works in New South Wales discusses the origin of the plant, the methods and cost of eradication, and proposes that a Noxious Weeds Bill should be introduced into Parliament.

THE report of the International Committee on Atomic Weights for 1907 is published in the current number (No. 310) of the Proceedings of the Chemical Society. New values are suggested, on the basis of determinations made during the past year, for bismuth, nitrogen, tantalum and terbium, and the opinion is expressed that alterations are needed in the atomic weights of silver and chlorine. Before, however, recommending any change as regards these elements, the committee deems it advisable to wait for fuller information of the results of determinations known to be in progress, as the new values for silver and chlorine will have an influence on a large number of atomic weights.

IN a paper on the relation of chemical activity to electrolytic conductivity by Mr. John L. Sammis, published in the *Journal of Physical Chemistry* (vol. x., No. 8), a large number of experimental observations are cited as disproving the views of Arrhenius and Ostwald that chemical activity in solution is proportional to the electrolytic conduction. The activity of acids in inverting sugar, catalysing esters, and dissolving magnesium is changed by the addition of benzene to the aqueous solution employed at a rate disproportionate to the conductivity. The replacement of one metal by another is said to take place in molten salts or solutions which are the best of insulators as well as in liquids which are good electrolytes. It was found that in sixty-nine non-conducting solutions of copper oleate prepared with different solvents copper was easily precipitated by lead, whilst in fourteen other non-conducting solutions lead did not replace copper. The general purpose of the paper is to emphasise the view that the solvent is not indifferent to the solute. It is contended that the facts brought forward are explainable only on the hypothesis that "chemical" union occurs between the solvent and the dissolved substance.

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN FEBRUARY:—

Feb. 8.	16h.	Venus at greatest elongation, 46° 53′ W.
,,	19h.	Venus in conjunction with the Moon. Venus 0° 51′ N.
9.	10h.	Minimum of Algol (β Persei).
12.	6h. 49m.	Minimum of Algol (β Persei).
15.	20h.	Vesta in conjunction with the Moon. Vesta 0° 42′ S.
19.	6h. 31m. to 9h. 33m.	Transit of Jupiter's Sat. III. (Ganymede).
20.	23h.	Conjunction of Mercury and Saturn. Mercury 1° 40′ N.
22.	6h.	Conjunction of Jupiter with the Moon. Jupiter 2° 45′ N.
,,	16h. 8m. to 16h. 58m.	Moon occults ν Geminorum (mag. 4·1).
23.	7h. 11m. to 8h. 29m.	Moon occults ζ Geminorum (variable).
25.	5h. 30m. to 6h. 31m.	Moon occults δ Cancri (mag. 4·2).
26.	10h. 12m. to 13h. 14m.	Transit of Jupiter's Sat. III. (Ganymede).

MICROMETER MEASURES DURING THE SOLAR ECLIPSE OF AUGUST, 1905.—At the meeting of the Paris Academy of Sciences held on January 7, M. J. Merlin submitted a paper discussing the micrometer measures made at Roquetas (Spain) by MM. André and Guillaume during the total solar eclipse of August, 1905. From this discussion he arrives at the conclusion that the lunar-parallax constant determined by Prof. Newcomb is not affected by any error sufficiently large to be detected by the measurements carried out. There is, however, room to correct the relative positions of the sun and moon as given in the *Connaissance des Temps*, although the correction does not modify the apparent trajectory of the moon in regard to the sun, it serves only to advance the position of the former in that trajectory by an amount corresponding to an advance of 11·1 seconds in the calculated times of the contacts (*Comptes rendus*, January 7).

HEIGHTS OF METEORS OBSERVED IN 1906.—In No. 4152 of the *Astronomische Nachrichten* Mr. Denning gives the heights, lengths of paths, and velocities of ten large meteors observed in England during 1906. The heights at the commencement of visibility varied from fifty-nine to eighty-nine miles, whilst those at disappearance varied from twenty-two to fifty-six miles. Seventy-two miles was the length of the longest path recorded, and twenty-four miles that of the shortest. The velocities determined lie between fifteen and thirty miles per second, the latter value having been determined for a Perseid observed on August 5, 1906.

A QUICKLY CHANGING VARIABLE STAR.—In Bulletin No. 9 of the Laws Observatory, University of Missouri, Mr. F. H. Seares discusses the observations of the quickly changing variable star RR Draconis (188.1904) which were made at that observatory during 1905–6. The variable is of the Algol type, with a period of about 2·8 days, and its light-curve is peculiar in being extraordinarily steep about the time of minimum. The latter could not be determined exactly, because the star becomes invisible for about two hours in the 7½-inch refractor employed, but the observations plainly showed that the range is greater than three magnitudes, and that the rate of change at the time of disappearance is one magnitude in half an hour. The normal magnitude of this object is 9·98, and the elements of its period, as determined from these observations, are:—

Min. = J.D. 2417026·682 + 2·831079d. F. G. M. T.

Some of the residuals suggest the possibility of a variation in the period, but for the present this possibility remains very uncertain.

METCALF'S COMET 1906*h*.—Another set of elliptic elements for comet 1906*h* has been calculated by Mr. Crawford from observations made at the Lick Observatory. This gives October 5·66, 1906, as the time of perihelion passage, and 8·23752 years as the period of the comet (Lick Observatory Bulletin, No. 108).

THE ERUPTION OF MATAVANU IN SAVAII, 1905–6

THE last-issued number of the *Zeitschrift der gesellschaft für Erdkunde zu Berlin* contains an account of a very remarkable volcanic eruption which had been in progress for more than twelve months in September last in the island of Savaii. The volcanoes of this island had been quiet for more than a century when, in 1902, two minor outbreaks occurred, and in 1905 a greater eruption commenced, causing so much anxiety and alarm that the German Colonial Administration sent to Prof. K. Sapper, of Tübingen, a collection of specimens, photographs, and newspaper and other reports, from which he has compiled an account which is interesting in spite of its inevitable incompleteness.

The eruption was ushered in by a series of earthquakes lasting from July 25 to August 1, 1905, at half past nine on the night of the last-mentioned date a loud detonation was heard, and shortly after "pillars of fire" were seen issuing from a valley known as Matavanu some 12 kilometres from the coast on the north-eastern side of the island. At first the eruption was of an explosive character, and does not seem to have been very violent, as the estimates of the height to which matter was thrown do not exceed 200 metres and the hill formed was never more than 150 metres in height. On August 9 lava began to flow, at first in small quantities, afterwards more abundantly, until it reached the coast on December 6, and flowed down to the sea at intervals up to the end of September, 1906, the date of the latest reports received by Prof. Sapper. During this period the outflow of lava seems to have been continuous, though varying in amount, and unaccompanied by any considerable degree of explosive activity.

Many people visited the volcano during the eruption, and an interesting account by Dr. Grevel is reprinted from the local newspaper. His party made the ascent on April 23 last, over the crust of the lava stream, which was smooth and easily traversed, and cool enough for the Samoans who accompanied him to walk over it. The solid surface of the lava stream was broken at intervals by vent holes, the one nearest the crater being at first mistaken for a parasitic cone, as the crust of the lava rose in a gentle convexity to the orifice, which was much smaller in diameter than the cavity underneath. Thick sulphurous vapours prevented any sight into the cavity, and large stones thrown in gave no clue to its depth, as their fall was unheard. Four of these vent holes were examined, which repeated the features of the first on a smaller scale, and the party then climbed to the crater by an easy ascent over the lava flow on the northern side. Owing to the drift of the south-east trade wind, no view of the crater could be obtained, so Dr. Grevel and his party worked round by the east, where the surface was covered with countless bodies of moths, attracted by the glow of the crater and killed by the vapours rising from cracks in the surface of the lava flow, the same vapours had proved fatal to a flying-fox, a dove, and a sea-gull. From the southern edge a good view of the crater was obtained, it was about 300 metres in diameter, filled with a lake of molten lava in gentle ebullition caused by the rise of steam bubbles, and from the centre a gentle streaming to the north commenced, which increased in rapidity until the lava disappeared in a cataract into a cloud of steam, and presumably joined the stream over the surface of which the party had ascended.

On reaching the sea, the lava flowed out to the reef, where its end, being cooled by the surf, formed a wall between which and the coast the lava flowed quietly along the lagoon. At its end the sea was in violent ebullition, dense clouds of steam were formed, and for 100 metres from the end of the flow the sea was boiling hot, and fishes, killed and cooked by this boiling sea-water, were collected and eaten by the natives. In a few places the lava flowed over the reef into the deep water outside, and where this occurred its progress was marked by violent geyser-like explosions, which were mistaken by some people for fresh volcanic eruptions, but were in reality due to steam formed under the still liquid lava. We reproduce a very striking photograph of one of these geyser-like explosions at the front of a lava stream flowing into the deep sea. The lava was remarkable for its fluidity, and issued in great quantity, according to a map attached to Prof. Sapper's paper the area covered by the lava extends about 6 kilometres to the west and 12 kilometres to the north-east of the volcano, and has a width of from 2 kilometres to 5 kilometres. It has filled the lagoon for about 8 kilometres along the coast, destroying several villages and rendering others uninhabitable by cutting off their water supply, while several small promontories of lava were thrust forward beyond the reef.

Lava flowing under its consolidated upper crust into the sea near Salago, September, 1906.

RESEARCH IN TROPICAL MEDICINE AND HYGIENE[1]

(1) THE greater part of the first report is occupied with an elaborate memoir by Drs. Thomas and Breinl on trypanosomes, trypanosomiasis, and sleeping sickness. It comprises a description of cases of sleeping sickness, a full account of inoculation experiments with the *Trypanosoma gambiense*, from which the conclusion is formulated that the trypanosomes of sleeping sickness of Uganda and of the Congo Free State and of trypanosomiasis are identical, together with an account of the pathological anatomy and histology of trypanosomiasis, the action of various drugs on trypanosomes, and experiments with the trypanosomes of surra, mal de caderas, dourine, &c.

The late Mr. Dutton and Dr. Todd contribute an important memoir on human tick fever in the Congo Free State, with an appendix by Mr. Newstead on the anatomy of the tick (*Ornithodoros moubata*) which conveys the disease.

[1] (1) "The Thompson Yates and Johnston Laboratories Report." Edited by Rubert Boyce and Charles Sherrington, with H. F. Annett, Benjamin Moore, Ronald Ross, and E. W. Hope. Pp. 141. Vol. vi. (New Series.) Part ii. December, 1905.
(2) *Ibid.* Vol. vii., Part i., February, 1906. Pp. 85+plates.
(3) "Rapport sur l'Expédition au Congo, 1903–5." Par J. Everett Dutton and John L. Todd. (École de Médecine Tropicale de Liverpool, Mém. xx.) Pp. 7? (All published for the University Press of Liverpool by Williams and Norgate, London, 1906.) Price 5s.
(4) "Second Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum." By Andrew Balfour.

Lastly, Surgeon Ross, R.N., contributes a short paper on the habits of the marine mosquito (*Acartomyia zammitii*).

(2) The second report contains papers on a new species of louse (*Haematopinus stephensi*) which acts as the intermediary host of a new hæmogregarine parasite in the blood of the Indian field rat, by Mr. Christophers and Mr. Newstead; a note on the anatomy of *Gastrodiscus hominis*, a human fluke, by Dr. Stephens; a revision of the Sarcopsyllidæ, by Dr. Karl Jordan and the Hon. N. C. Rothschild, a family of fleas which includes the jigger, and the rat flea supposed to transmit plague to man; and a description of the maiotic process in Mammalia, by Messrs. Moore and Walker. The last-named paper is illustrated with a number of beautiful plates, and is well worthy of study.

(3) In this report the late Mr. Dutton and Dr. Todd, after some general remarks on the conditions favouring the spread of malaria, describe the conditions existing at some of the towns and posts of the Congo Free State, and formulate recommendations for remedying these. Dr. Breinl and Mr. Kinghorn describe experiments showing that the Spirochæte of African tick fever is infective for the horse, dog, rabbit, guinea-pig, rat, and mouse, in addition to monkeys, whereas the *Spirochaeta obermeieri* of relapsing fever is infective for monkeys only. Dr. Breinl has also compared the immunity produced by these two Spirochætes, and finds that each strain produces considerable active immunity against re-infection, but does not produce immunity against infection with the other strain. The course of the disease also varies with the two strains, and the conclusion therefore is that tick fever and relapsing fever are produced by different species of Spirochætes.

(4) The second report of the Wellcome Research Laboratories of the Gordon College, Khartoum, by Dr. Andrew Balfour, the director, maintains the high standard of the first one (see NATURE, vol. lxxi., p. 605) both as regards the nature of the work recorded and the manner in which it is presented to the reader. Nearly half the volume comprises records of mosquito work in Khartoum, of biting and noxious insects, mosquitoes and other human, animal, and vegetable pests of the Sudan. Dr. Balfour describes a hæmogregarine parasite of the jerboa and a leucocytozoon of mammals, and contributes a report on cattle and equine trypanosomiasis in the Anglo-Egyptian Sudan. Fortunately human trypanosomiasis and sleeping sickness do not yet seem to be endemic in this part of Africa, nor has the tsetse fly which conveys it (*G. palpalis*) been described here. In the chemical laboratory a considerable amount of work has been done by Dr. W. Beam, the chemist, on water analysis, Sudan grains and gums, &c. The travelling naturalist, Mr. Sheffield Neave, records many interesting observations on blood, blood parasites, &c., of birds, fish, and other animals.

R. T. HEWLETT.

PRESIDENTIAL ADDRESSES AT THE NEW YORK MEETING OF THE AMERICAN ASSOCIATION.

A GENERAL article upon the proceedings of the American Association for the Advancement of Science at the meeting held at New York during the Christmas vacation appeared in NATURE of January 24 (p. 304). Through the kindness of the general secretary of the association, Dr. L. O. Howard, we have received copies of several of the addresses delivered by the president and by the chairmen of sections, but limitations of space will not permit us to publish any of them in full. The subjoined extracts from these addresses will, however, afford an indication of the subjects considered and the views expressed.

EDUCATIONAL THEORIES, ANCIENT AND MODERN.[1]

The Greek idea of education and culture was based upon the existence of a privileged class, fed, clothed, and sheltered by the labour of slaves—a real aristocracy devoted to war, art, literature, and luxurious living. The sway of the so-called classic idea of education has been, and still is, one of the marvels of history. The splendour of Greek art, the brilliancy of Greek literature, and the keenness of Greek logic, have held the world as in a trance, unable to break away from its charms—though it has been unsuited to other peoples and other social conditions.

Francis Bacon more than any other man showed the inadequacy of the classic method, fine as it was along certain lines, and the comparative worthlessness of scholasticism, and he opened the eyes of the educated people of his time to the wealth of opportunity for interesting and profitable study in the great laboratory of nature, and, better than all else, he set forth the dignity and intellectual value of science study, and vigorously scouted the idea that the usefulness of scientific truth in any degree detracted from its educational value.

But none of the writers touching on education, with the possible exception of Froebel and Pestalozzi, not even Locke, Milton, or Dr. Samuel Johnson, looked at the matter from the scientific standpoint, which takes into account, first, the physiological laws which govern the growth and development of the brain; secondly, the exterior stimuli for promoting that growth most successfully; and, thirdly, the kind and quantity of knowledge and skill one must have in order to meet most completely the demands of a carefully selected occupation.

Every good teacher aims to make his subject as interesting as possible to his pupils. If they fail to take a lively interest in it something is wrong: either it is not properly presented, or it is over their heads, or it is clearly of no earthly use. Natural lack of capacity on the part of the child is rarely a valid reason for failure if the child be healthy and normal. I have learned to discredit the truth of the oft-told tale that "John has no capacity for" such a subject—mathematics, for example. "He never could learn mathematics—he takes no interest in algebra, and he hates geometry," &c. Our higher schools and colleges are full of young people who protest vigorously that they never could, and never can, understand or take any pleasure in or gain any profit from certain studies. I firmly believe that every normal person, at least nine out of ten of the children and youth at school and college, can fairly master and actually enjoy and profit by not only mathematics but by every subject in the curriculum if it be properly taught and under proper conditions as to age and preparation.

Attention is as necessary to the growth and development of the brain as exercise is to the development of a muscle, and interest is the condition of a lively attention. When in a school or lecture-room the limit of close attention is reached, the lesson or lecture should close, for the educational process has already stopped. It is not only useless but it is worse than useless to go on when the class or audience refuses for any reason to attend. I therefore doubt the educational value of subjects which are not, and perhaps cannot be, made interesting.

Of course I do not claim that all selected studies can be made equally interesting, or that any one study can be made equally interesting to all pupils, even when the pupils are properly graded; but I do claim that a lively interest is necessary, and that educational progress is very nearly proportional to the strength of that interest.

Perhaps the most valuable contribution to the science of education has come through a study of the laws which obtain in the growth and development of the brain, and the conditions under which that growth and development is most healthy and complete. There are times and seasons for the development of the mental and moral faculties as there are of the physical faculties. While such times and seasons are not precisely the same for all children, we find that all attempts at premature development are not only worthless, but are permanently injurious. Precocity is now regarded as a species of brain deformity. Plants and animals may be forced, and unusual and interesting results may be produced by forcing, but no one of us wishes a son or a daughter to be a prodigy in one direction at the cost of normal development in other directions.

The psychologists tell us that the brain-cells develop as do other physical organs, not only through thought,

[1] From an address delivered by Prof. C. M. Woodward, president of the American Association.

but through muscular activity and the exercise of our senses Accordingly, a healthy and timely growth and development of the brain is to be promoted by an education involving a great variety of activities, skilfully adjusted as to quality and quantity to the mental and physical status of the child

Closely related with this of brain culture is the subject of manual training, which has recently gained a foothold in our scheme of rational education Its nature and educational value are still under discussion

The manual-training movement stands inevitably as a criticism upon the system of education which came down the ages through the fathers to us, and naturally the latter stands on the defensive It also is a standing reproof to the old wasteful, unscientific method of teaching apprentices the theory and uses of tools It is for educational science to justify the ways of progress, which lays aside the idols of the past and erects new temples and opens new kingdoms Of all the temples, none is finer, none is more glorious, and none should be more scientifically planned and reared than education

The evolution of the fully fledged technical school, or the technical department of the university, has taken place during the last half-century, and yet its broad, stimulating attractive features have a following which bids fair to double the attendance of college and university students This does not mean that letters and polite learning are being neglected but that a new constituency is eager for the new education This new education though it recognises it all points a high order of usefulness and contains little that is conventional, is only remotely professional If ever its curriculum becomes narrow it is quickly condemned by the best representatives of an education which combines utility with culture No longer can the "Levites of culture" as Huxley calls them claim to monopolise liberal education The new education can be as liberal as the old, and both can be narrow Fortunately, they flourish side by side and the future shall choose the excellences of each An adequate science of twentieth-century education will evaluate the characteristics of each and bring the wisdom of the past, not its foolishness, to nourish the wisdom of the future

ACCURACY OF ASTRONOMICAL CLOCKS [1]

The accuracy with which our astronomical clocks perform their function is a subject of interest The earliest star catalogue of precision is that of Bradley In discussing the performance of his clock I have used the adopted rates as given by Auwers in his re-reduction of Bradley The monthly means of the rates from July, 1758 to July 1759, were taken, and the difference of each rate from its monthly mean Then the mean of these differences, without regard to sign, was taken for each month

The rates of two other clocks of the Greenwich Observatory were likewise discussed, the standard clock for the year 1850 and that for 1900, the adopted daily rates as published in the annual volumes being used The first of these was kept in the observing room, and thereby subjected to large variations of temperature while the second made in 1871 by E Dent and Co , was fixed to the north wall of the magnetic basement, as in this apartment the temperature is kept nearly uniform. The pendulum of this latter clock is provided with barometric as well as thermometric compensation

There are two well-known clocks which should be mentioned, and in conclusion I will give some hitherto unpublished data concerning the clock with which I have been working during the past three years

Probably no clock has had its rate more thoroughly discussed than Hohwü No 17, the standard clock of the observatory at Leyden It was set up in the transit room in 1861, and in December, 1898, was removed to the large hall of the observatory, where, enclosed in two wooden cases, it was placed in a niche cut in the pier of the 10-inch refractor Further, to guard against sudden changes of temperature, the niche is closed by a glass door At the meeting of the Royal Academy of Sciences at Amsterdam held September 27 1902, Dr E F van de Sande Bakhuyzen submitted a formula as the best representation of the daily rate of the clock and gave the result of a comparison of the observed daily rates 1899–1902, the average interval of time for each rate being six days, with those computed by means of the formula I find that during the year 1900 the mean of these differences is 0·028s , and the largest difference is 0·071s

About 1867, Tiede installed at the Berlin Observatory a weight-driven clock enclosed in an air-tight case The original escapement was replaced in 1876 by a gravity escapement, and the clock continued to give satisfaction certainly up to 1902, when it was dismounted for cleaning The only published rates that I have been able to secure are those during twelve weeks in 1877–8 During this period the average deviation of the observed daily rates the average interval for each rate being six days, from the mean daily rate for the entire period is 0·030s

In 1903 there was installed at the U S Naval Observatory one of Riefler's clocks, No 70, with a nickel-steel pendulum, the impulse being communicated to the pendulum through the suspension spring This clock was enclosed in an air tight glass case and was mounted in a vault where the temperature was artificially controlled The definitive rates have been determined from September 1903, to May 1904, but unfortunately during this entire period we were unable to prevent the glass case leaking and there was a variation of temperature in the vault of about 5° C

Collecting together the results obtained we have —

Mean Deviation of Daily Clock Rate

Clock	Date	Mean Deviation
Bradley	1759	0·102
Greenwich Observatory	1850	0·149
Greenwich Observatory	1900	0·051
Berlin Observatory	1877	0·02 0·03
Leyden Observatory	1900	0·028
U S Naval Observatory	1904	0·015

FACT AND THEORY IN SPECTROSCOPY [1]

Any treatment of the production of radiation falls more or less naturally into three parts, namely (1) the radiation of solid and liquid bodies which is almost, but not quite, independent of atomic structure, (2) the radiation which takes its rise in radio-active substances and which is apparently dependent upon atomic collapse, and (3) the radiation of gaseous substances, dependent almost entirely upon normal atomic structure, and possibly also upon the mode of excitation

The subject to which consideration is now invited has to deal only with radiation of this third class Radiation which in terms of the electron theory is said to be due, not to abrupt or discontinuous acceleration, but to periodic acceleration

Briefly defined, spectroscopy is that science which has for its object the general description of radiation including the production of radiation, the analysis of radiation the registration of radiation, and the measurement of radiation

The theory of separating, recording, and comparing radiation is by no means simple or complete That these last three operations demand in practice the highest degree of skill is exemplified by the work of Rayleigh, Rowland, Michelson, Perot and Fabry, and Hale

There is however, a certain very true sense in which these last three processes are merely preparatory to a more profound study of the first, namely the production of radiation From this point of view, spectroscopy hinges upon the radiant atom—if there be an atom—and may be defined, imperfectly and narrowly perhaps, as *the science of the radiant atom*

More than one brilliant and partially successful attempt has been made within the last quarter-century to establish an adequate foundation for this science by devising what may be called a satisfactory atom But before considering any of these attempts, it may be well to state briefly what seems to be the criteria by which any such foundation is to be judged

Perhaps it may be fair to consider that atom is most competent which will explain satisfactorily the largest number of the following nine facts —

[1] From an address delivered by Prof W S Eichelberger chairman of the Section of Mathematics and Astronomy

[1] From an address delivered by Prof H Crew, chairman of the Section of Physics

(1) The fact that spectral lines are in general approximately sharp

(2) The fact that spectral lines are never perfectly sharp but always have a finite physical width

(3) The fact that certain spectral lines are arranged in series and bands after the manner described so perfectly by Balmer's equation and its generalised forms

(4) The fact that increase of pressure causes a shift of spectral lines toward the red, as discovered by Humphreys and Mohler

(5) The fact that a magnetic field will transform single lines into multiple polarised lines, as discovered by Zeeman

(6) We come now to a group of phenomena which are not easily described under a single caption I refer to phenomena such as those observed by Plucker and Hittorf when they found one and the same gas in one and the same tube yielding very different spectra according to the mode in which the electric discharge was applied to make the gas luminous In the same category doubtless belongs the extinction of air lines by the insertion of self induction into the discharge circuit Here may belong also the fact studied by Lenard and others that the region near the electrode of an arc gives a spectrum different from the region near the centre of the arc, the fact also that the so-called 'spark lines' are introduced into an arc by reducing the current to small values, a fact first studied by Hartmann

Certainly in this same category belongs the fact that the spectrum of an arc is modified when the arc is surrounded by an atmosphere different from ordinary air

Here also lie the profound differences between arc and spark spectra of the same element

Notwithstanding the fact that 'multiple spectra' is a term which has hitherto been employed to describe the Plucker tube variations I propose that we generalise it and use it to describe this entire group of facts Since the name is so appropriate let us call the sixth fundamental phenomenon that of "multiple spectra"

(7) Any competent atom must allow us to infer the relations which have been proved to exist between spectral phenomena and atomic weights

(8) The phenomena of line reversals and absorption bands

(9) The fact that heat alone at least within the range of our highest artificial temperatures produces characteristic spectra in only a few rare instances

These briefly are the parts of the spectroscopic superstructure for which a foundation is sought These are the various parts which it is hoped will, some day, be cemented together by a simple and general theory, into a harmonious structure

But there is a final criterion even more fundamental than any of those which have been mentioned that such a theory must satisfy, namely this hypothetical radiant atom must not in its behaviour except as a very last resort contradict any of the established principles of physical science be they mechanical electrical, or chemical

The principle of the conservation of energy must be satisfied even if it is necessary to assign an undreamed of amount of energy to each atom in like manner Newton's third law is to be satisfied even if the electromagnetic ether is called upon to furnish the reaction

But even with this added criterion the preceding list of nine phenomena is confessedly incomplete the only object of such a catalogue is to include those typical fundamental facts which ought apparently, to follow as immediate consequences from the structure of the radiating body so soon as that structure is correctly guessed Thus Doppler's principle is omitted on the ground of its being rather a kinematic law governing periodic disturbances in any medium than a dynamical fact to be explained in terms of atomic structure and forces

Having established a set of criteria by which we may estimate the fitness of a radiant atom, it would be interesting, if I were competent, and if time permitted, to pass in review some of the various atoms which have been proposed in recent times, such as that of Kelvin, 1884, or those suggested by the Hertzian oscillator

But neither of these two conditions are fulfilled and I propose, therefore to consider only one atom, namely, the one which by common consent, I think I may safely say, more nearly satisfies the demands of experimental fact than any other ever devised I refer to the atom first proposed in a general way by Lord Kelvin in his paper entitled "Epinus Atomised" (Baltimore Lectures, p 541, Cambridge, 1904), and afterwards profoundly modified by Lorentz, Thomson, and Larmor

So much work along this line has been done in the Cavendish Laboratory that one feels impelled to call this 'the Cambridge atom", in view, however, of its structure perhaps "the Saturnian atom" is a more appropriate designation

THE CONTRIBUTIONS OF AMERICA TO GEOLOGY[1]

In speaking of the contributions of America to geology, I do not propose to give an inventory of the geological facts which have been made known as the result of work in this country I propose rather to ask the question, 'What has our country contributed to the stock of geological ideas?" In that classical history of geological science which Lyell has given us in his "Principles of Geology," he directs attention to the fact that the share which different nations bore in the early development of geological science was dependent, not alone upon the genius of individual workers but in large measure upon the peculiar geological conditions of the various countries in which they worked

Of course, it must be admitted that there is to-day no department of geological science which is as characteristically American as mineralogy was German, as dynamical geology was Scotch, as stratigraphical geology was English, and as palæontology was French a century ago I believe, nevertheless, that there have been certain contributions to the stock of geological ideas which are characteristically American

The doctrine of the permanence of continent and ocean —the gradual emergence of continental lands and the withdrawal of the waters into the deepening ocean basins—was first enunciated by Dana in 1846 It was, apparently, the thought of the subsiding ocean bottom rather than the thought of the emerging land by which Dana was first led to the doctrine of the permanence of continent and ocean but in his presidential address before the American Association for the Advancement of Science in 1855, Dana refers to the stratigraphy of New York as illustrating the idea of continental emergence The doctrine of the permanence of continents when announced by Dana was essentially a new one Geologists and pseudo-geologists of all classes had felt at liberty to redistribute continents and oceans according to their own sweet will

There is now little doubt that Dana was right in his general conception The greater density of the suboceanic masses in comparison with the subcontinental masses, as shown by pendulum observations, indicates that the distinction between continent and ocean has its basis in the heterogeneity of the material in the interior of the earth, and the determining conditions must therefore have had their origin in the initial aggregation of that part of the primitive nebula which formed the earth

Certain it is however that Dana made the evolution of the continents too simple an affair He recognised indeed, that the progressive emergence of the continental lands was attended by continual oscillation, yet, even in the last edition of his "Manual" it appears that he did not duly appreciate the magnitude of those oscillations The doctrine of the progressive evolution of continents, as taught by Dana gave new clearness and emphasis to the general conception of geology as a history of the globe

The Geological Survey of Pennsylvania made known the folded structure—the alternate anticlines and synclines—of the Appalachians The beautiful sections of these folded strata, in the atlas of that survey, reveal the thoroughness with which the structure of the mountains was investigated by Henry D Rogers

While the stratigraphy was worked out so beautifully in the first geological survey of Pennsylvania the dynamic conception derived from it was crude indeed But, however completely the Pennsylvania geologists failed to con-

[1] From an address delivered by Prof Wm North Rice, chairman of the Section of Geology and Geography

struct a satisfactory theory of mountain-making, their observations of Appalachian structure were of immense value in their destructive effect upon some of the notions of mountain-making prevalent at the time.

The true interpretation of the Appalachian waves is probably to be found in the contractional theory of mountain elevation, of which Dana was the leading expounder. That the main cause of mountain elevation is tangential pressure in the crust resulting from internal contraction is now generally acknowledged, though there may be doubt whether the main cause of contraction is the cooling of the earth from an incandescent condition.

It is a curious fact that the first published suggestion of the agency of ice in connection with the drift came from a cotton manufacturer in Connecticut, Peter Dobson by name. The credit of the introduction and championship of the glacier theory of the drift belongs, not to a native, but to an adopted citizen of this country. In the early papers of Agassiz, the conception of the Glacial period took a form which he himself later recognised as an exaggeration. He conceived at first a fall of temperature so widespread that a polar ice-cap extended southward over the whole breadth of Europe and across the Mediterranean, reaching the Atlas Mountains. Later he recognised the ice-sheet that covered the Alps as entirely separate from the ice-sheet of northern Europe. The tendency to an exaggerated view of the Glacial period overcame him again in later years, when he maintained that at the climax of the Glacial period there was "floating ice under the equator, such as now exists on the coasts of Greenland." As Agassiz travelled in various parts of his adopted country, he recognised everywhere in the northern States the traces of glaciation already familiar to him in Switzerland and in Scotland.

Within the last few decades the labours of earnest and able investigators have developed the glacier theory more in detail, and have added vastly to our knowledge of Quaternary history. The imaginary polar ice-cap has given place to ice-sheets of more limited dimensions, though still vast. The series of terminal moraines, marking stages of re-advance or halts in the retreat of the ice-sheet, have been carefully mapped.

In early years the study of geology in this country was substantially confined to the region east of the Mississippi; but, in due season, the weird and fascinating region of the Cordillera revealed itself to explorers and geologists. It is now more than half a century since American geologists began the study of that western wonderland. The first lesson that geologists learned in that land was the efficiency of subaerial denudation to remove vast quantities of material and shape the topography of wide areas. That western land has taught us, not only to recognise the fact of subaerial denudation, but also to formulate its methods. In Powell's "Exploration of the Colorado River," he distinguished rivers as consequent, antecedent and superimposed. Davis has carried the analysis somewhat further, giving us subsequent and obsequent rivers. Powell formulated the doctrine of base-levels; Davis has given the conception greater accuracy and consistency by distinguishing base-level from profile of equilibrium. To Davis also we owe the full development of the conceptions of youth and age in river valleys and in drainage systems, and of cycles of erosion ending in the formation of peneplains.

Half a century ago the exploring expeditions connected with the Smithsonian Institution began to collect fossils from the Tertiary deposits of the western plains. Over those western plains were found to stretch vast continental deposits, certainly not all of lacustrine origin. These continental deposits of the western plains yielded in unparalleled richness mammalian fossils, which have been studied by Leidy, Marsh, Cope, Osborn, Scott, Wortman and others. No other single series of discoveries has been so potent in changing the bearings of palæontology upon the doctrine of evolution.

In the half-century since the publication of Darwin's first edition, the attitude of palæontologists has completely changed. Not only is it true at present that palæontologists are substantially unanimous in accepting the doctrine of evolution, but it has come to be generally believed that the very science which afforded a half-century ago the strongest objection to evolution now affords its strongest support.

When the first edition of the "Origin of Species" was published, the classes of birds and reptiles seemed to stand widely asunder. But in the very next year (1860) an odd feather of Archæopteryx was discovered, and a year later the skeleton now preserved in the British Museum; but Archæopteryx was a solitary representative of the birds of markedly reptilian character until the discovery of Ichthyornis and Hesperornis in the Cretaceous of Kansas, of which preliminary descriptions were published by Marsh in 1872.

But the discoveries of most evolutionary significance, as already intimated, have been among the Tertiary mammals. A number of series has been traced leading from generalised types in the Eocene through forms of gradually increasing specialisation, to genera which still survive.

SOME PHASES OF PREHISTORIC ARCHÆOLOGY.[1]

Are eoliths artifacts? This is the fateful question. Their geological age is of no consequence if they are only natural forms and have never been used by man or his precursor. The first flakes to be utilised were in all probability natural forms. It is not likely that Eolithic man knew how to obtain the raw material from the chalk. He depended on picking up from the drift flakes of approximately the shape and size needed. A sharp edge was utilised once, twice, or until it became dulled, and was then cast aside. If an angular piece did not admit of being comfortably grasped in the hand, the troublesome corners were removed. Such conclusions as these are forced upon one after careful examination of a series of the specimens in question. Would the same conclusions be so irresistible if these objects were merely nature's playthings? Many may even be grouped according to more or less definite patterns. Two of these deserve special mention, viz. the small crescent-shaped scrapers comparable to the spoke-shave, and the double scrapers with an intervening point between the two scraping edges. Sometimes two margins are worked but on opposite sides; that is to say, after chipping one of the margins, instead of rotating the specimen until the adjacent margin comes into play, it was reversed.

The wide differences of opinion as to the origin of eoliths can hardly be due to prejudice alone. Faulty or insufficient observation and incorrect interpretation doubtless play their part. Luckily there is no disposition to drop the matter until the truth appears. At the International Congress of Anthropology and Prehistoric Archæology held at Monaco April 15–22, 1906, the chief subject of the second session was the pedigree of the eolith. According to NATURE (June 28, 1906, p. 211), "a series of mill-modelled flint nodules was exhibited, among which there was certainly a number closely resembling many Prestwichian types, but conspicuous by their absence were the decidedly purposeful and rationally usable Kentian forms." On the other hand, Prof. E. Ray Lankester "submitted that he had recently placed on exhibition in the British Museum a considerable series (*Amer. Anthropol.* (N.S.), 1905, vii., 432, 433) of specimens selected from Prestwich's collection, all borer-like in form, too identical in shape and so rationally of obvious utility for any possibility of their being the result of fortuitous natural collisions."

As a further indication of the importance attaching to a correct solution of the problem, and indirectly in recognition of the value of Rutot's contribution toward such a solution, the meeting of the German Anthropological Association for 1907 will be held in Cologne in order that the members may visit the eolithic stations of Belgium and see the collections of the Brussels Museum.

Of caverns with Palæolithic mural decorations outside France, thus far reported, one is in Italy and four in Spain. The most important cavern in the Spanish group is that of Altamira, in the north coast province of Santander, this being the one in which the discovery of mural figures first took place. The genuineness of these figures would have continued to remain in doubt

[1] From an address delivered by Prof. MacCurdy, chairman of the Section of Anthropology.

had it not been for similar subsequent discoveries elsewhere.

M. Émile Cartailhac and the Abbé H. Breuil have recently studied with great care the wall paintings and engravings at Altamira. The cavern is a series of large chambers connected by passage ways. There is no evidence of its having been occupied by either man or beast since the close of the Quaternary, at which time the entrance was completely closed by a fall of earth and stones.

A second recent fall has afforded a new opening to the cavern, reached by clambering over the débris that closed the original entrance. The first chamber is divided by means of a mass of fallen stones. The one on the left is 40 metres long by 20 metres wide. The one on the right is a sort of corridor connecting with other chambers. Industrial remains of the floor deposits are confined to the entry and the chamber on the left. There is evidence that the cave bear had occupied the cavern before man took possession. Figures, engraved or painted, are found on the walls of every part of the cavern, especially on the ceiling of the chamber on the left near the entrance, where the frescoes are remarkable for their beauty, size, and good preservation—a sort of Sistine chapel representing the *chef d'oeuvre* of perhaps more than one Michael Angelo of that far-off time.

These works of art represent a variety of technique. Some are simple line engravings. Others are more deeply incised. But the engravings are not so numerous as the figures represented in colour. Many are done in a single colour, either red or black. The most remarkable are the polychrome frescoes similar to those of Font-de-Gaume already described.

The figures are not all animal representations. Many are signs the significance of which is not known. They do not belong to a single epoch. The superposition of figures, each in a different technique, studied in connection with the relative state of preservation of the various figures, has furnished a key to the order of succession. The same succession is traceable in the caverns of France, so that the Abbé Breuil and his colleagues MM. Cartailhac, Capitan, Peyrony, and Bourrinet have been able to distinguish four distinct phases[1] in the evolution of mural painting and engraving, all of them being represented in the cavern of Altamira.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The following Graces passed the Senate at Congregations held on February 1 and 2:—(1) That in accordance with recommendation i. contained in the third report, dated November 15, 1906, of the special board for mathematics on the mathematical tripos, the regulations for the mathematical tripos, part i., contained in the report be approved (placet, 776; non-placet, 644). (2) That in accordance with recommendation ii. of the same report, the regulations for the mathematical tripos, part ii., contained in the report be approved (placet, 780; non-placet, 638). (3) That in accordance with recommendation iii. of the same report, the temporary provisions for the mathematical tripos, alike under the old regulations and the new regulations, contained in the report, be approved (placet, 777; non-placet, 637).

The Adams prize for 1907 has been awarded to Dr. E. W. Brown for his essay on "The Inequalities in the Moon's Motion due to the Direct Action of the Planets."

Mr. Douglas W. Freshfield will deliver a public lecture on Ruwenzori at the Sedgwick Museum on Thursday, February 14. The lecture will be illustrated by lantern pictures, including many taken during the Duke of the Abruzzi's expedition.

The special board for biology and geology has nominated Mr. C. Shearer, Trinity College, to use the University table at Naples for three months from March 1.

MR. FRANCIS GALTON, F.R.S., has given a further sum of 1000*l.* to the University of London in aid of the study of national eugenics founded under his previous benefaction. Mr. David Heron has been appointed Galton research fellow in national eugenics, in succession to Mr. Edgar Schuster, resigned.

SIR COWASJEE JEHANGHIR READYMONEY has, says the *Times*, offered to the Bombay Government the sum of 2½ lakhs of rupees (16,666*l.*) for the erection of a university examination hall in Bombay, thus following the munificent example of his father in giving to the city the Elphinstone College buildings and the Senate hall of the University.

THE annual general meetings of the Association of Technical Institutions will be held at the Clothworkers' Hall, Mincing Lane, E.C., on Friday and Saturday, February 8 and 9, as follows:—on Friday afternoon the presidential address will be delivered by Sir Horace Plunkett, K.C.V.O. On Saturday morning the following papers will be read and discussed:—the cooperation of adjacent authorities in the supply of higher technical education, Principal A. F. Hogg; monotechnic institutions, Mr. Charles Harrap.

SIR A. B. W. KENNEDY, president of the Institution of Civil Engineers, speaking at a dinner given by the Carpenters' Company on Monday to a number of eminent members of the engineering profession, remarked that the idea of thirty or forty years ago that the training of an engineer should be specialised has passed away. It is now recognised by all engineers that their profession is one at bottom, and that therefore an engineer should have a thorough general training in scientific work which should be the basis of all his future work, and that he should only specialise when it is necessary to do so to earn his daily bread.

THE inaugural lecture to the courses on Japanese education, to be delivered under the Martin White benefaction in the University of London by Baron Dairoku Kikuchi during the spring and summer terms, will be given at the University, South Kensington, on Thursday, February 14, at 5 p.m. Sir Edward Busk, Vice-Chancellor of the University, will preside. Admission to the inaugural lecture will be free by ticket, obtainable on application to the academic registrar at the University, South Kensington. Arrangements have been made for a course on Japanese educational administration to be delivered at the London School of Economics, and for courses on Japanese educational methods to be delivered at University College, Gower Street, and King's College, Strand.

THE annual court dinner of the Leeds University was held on Thursday, January 31, and was attended by His Excellency Baron Komura, the Japanese Ambassador to this country, as the chief guest. Among those present were the High Sheriff of Yorkshire, the mayors of many neighbouring boroughs, representatives of various education authorities, technical institutions, grammar schools, and other bodies. Baron Komura, in proposing the toast of the University, referred to the debt of gratitude which Japan owed to the educational institutions of England, and among them to the University of Leeds, which has numbered a good many young Japanese amongst its students. Since the granting in 1904 of the Charter establishing the University, a new capital fund has been raised by private donations which now amounts to 82,300*l.* New buildings are in progress to accommodate the department of mining and metallurgy, and other important extensions rendered necessary by the growth of numbers in the University are under consideration.

THE council of the University of Manchester has decided to institute two new lectureships, one in economic zoology and one in economic botany. The lectureship in economic zoology will provide further instruction in special subjects for the senior and honours classes in zoology, and the lecturer will devote a portion of his time to the preparation of reports on animal parasites and pests. An important part of the duty of the new lecturer will be to conduct research on such subjects as the fauna of reservoirs and sewage conduits, the life-history of animal parasites, and on other matters of economic importance. The lecturer in economic botany will give instruction to

[1] A fifth and closing phase is discernible at Marsoulas, resembling somewhat the work on the painted pebbles of Mas d'Azil.

special classes, and will assist in arranging and making accessible to students and to the public the collections of plants and plant products possessed by the University. It will also be his duty to examine and report upon such specimens of plant diseases, of timbers, and of other vegetable products, as may be sent to the University and to the Manchester Museum for identification, and to conduct special researches in economic botany.

THE annual distribution of prizes and certificates to the successful students attending the colleges and schools conducted in London by the City and Guilds of London Institute, was held at the Mansion House on January 31. The Lord Mayor presided. Sir Edward Busk, Vice-Chancellor of the University of London, in the course of an address referred to the suggestions of the departmental committee of the Board of Education for the amalgamation of the Royal College of Science, the Royal School of Mines, and the Central Technical College at South Kensington in one great technical college. He sees no reason why such a scheme cannot be carried out. The Royal College of Science would be the nucleus of the scientific side of such a technical college, and the Central Technical College would be the nucleus of the engineering side. He earnestly hopes that the governing body of the new institution will take measures to ascertain that candidates for admission already possess a sound general secondary education. At present the students who come up have not sufficient general knowledge and culture. Sir J. Wolfe Barry, in proposing a vote of thanks to Sir E. Busk, expressed the hope that a start would soon be made with the development at South Kensington of a great college for technical education.

AMONG the most recently announced gifts to American seats of higher education may be mentioned the following, recorded in *Science*. As already announced by cable (p. 237), Mr. J. D. Rockefeller has given the University of Chicago 540,000*l*. for its permanent endowment, and 43,400*l*. for current expenses and special purposes. Among the special provisions of this latter gift is one to provide permanent increases in the salaries of instructors, 8000*l*. Mr. Rockefeller's gifts to the University of Chicago are said to amount to more than 4,000,000*l*. It is announced that 65,000*l*. have been subscribed toward the 100,000*l*. endowment which is being raised to mark the seventy-fifth anniversary of Lafayette College. Of this sum, Mr. Andrew Carnegie has given 10,000*l*. for a mechanical engineering course. He will give an additional 10,000*l*. provided the 100,000*l*. is obtained. A further gift of 10,000*l*. from Mr. Andrew Carnegie to Bates College is announced. Mr. Carnegie's offer of this amount stipulates that friends of the institution shall subscribe 20,000*l*., and this amount has been secured. Mr. Carnegie has also given 150,000*l*. for the construction of a building to be used by the Bureau of American Republics. Provision for the site already has been made by the United States and the South American Republics.

A LONG communication to the *Times* by Mr. A. Mosely again directs attention to American methods of education. Mr. Mosely recently returned from the United States and Canada, where he went to prepare for the arrival of British teachers who are now at work visiting American schools and studying Western systems of education. He tells a gratifying story of the kindness of the welcome accorded to the visitors. The interchange of views between two great English-speaking peoples must be of enormous benefit to those who are trying to work out practical systems for the education of future generations. Already the British teachers have been impressed with the great belief in the value of education shown by Americans. Mr. Mosely points out that this belief in education finds a ready echo amongst all classes of society, who are prepared to pour out money, both through taxation and by princely gifts for education. The material advantage of the American system of education is manifesting itself by the prosperity of the country and by the flow of inquiries at the doors of every university and place of higher education for the services of the students as they graduate. In fact, there are many applications for every pupil available. One of the most noticeable features in the United States is, the letter continues, the desire of the pupil, ably backed by the parent, to take full advantage of the magnificent system afforded by the country of practically free education from the kindergarten to the university.

THE final report of the Royal Commission on Trinity College, Dublin, and the University of Dublin has been published. The recommendations of the commissioners and the decision of the Government as announced by Mr. Bryce in reply to a deputation on January 25, have given rise to much discussion. The difficulty in connection with the establishment of a satisfactory system of university education in Ireland is a religious one. As the first conclusion of the commissioners states, Trinity College has been and is a satisfactory organ for the higher education of the Protestant Episcopalian population of Ireland, but it has never been and is not now to an extent adequate to the reasonable requirements of the country, an organ for the higher education of the Roman Catholic population. The important matter is somehow to secure for all Irishmen who desire it the benefit of university education, and, in view of this paramount necessity, we welcome the scheme outlined by Mr. Bryce as being likely to consolidate educational effort and to free institutions of higher instruction from impediments arising from sectarian animosities. The Government appears to have decided that the University of Dublin shall be enlarged so as to become a national university for Ireland, which will include as constituent colleges—Trinity College, a new college in Dublin, and the Queen's Colleges in Cork and Belfast. In regard to the new college, it is to be furnished with adequate buildings and laboratories, and it is hoped that on the science side use may be made of the Royal College of Science, and that its laboratories and apparatus will be the means of effecting the change economically. The funds at present used by the Royal University—which is purely an examining body—are to be employed for the purposes of the new college and the proposed University of Ireland generally. It is intended that the new university shall be absolutely unsectarian, and that there shall be no tests for governors, fellows, teachers, students, or examiners. Though there are signs already that the proposals of the Government will in some quarters meet with great opposition, we are hopeful that it will prove possible to establish in Ireland a comprehensive university which will include eventually every Irish seat of learning reaching a proper university standard.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 22, 1906.—"The Relation of the Kidneys to Metabolism." By F. A. **Bainbridge** and A. P. **Beddard**. Communicated by Prof. E. H. Starling, F.R.S.

The effects of removing the greater part of the total kidney weight of cats were studied; a portion of one kidney was removed at one operation, and some weeks later the opposite kidney was removed. After the second operation the animals refused food and lost weight, though not more rapidly than normal cats kept for twenty-four hours without food. The increased output of urinary nitrogen described by Bradford was not invariably observed, but in some cats which refused food after the second operation the output of nitrogen was increased, though not to the amount found before the second operation. Moreover, the output of urinary nitrogen did not rise until the animals had lost about 25 per cent. of their body weight. A similar rise of nitrogen has been found by many observers in normal animals when the body fat has been largely used up and energy has to be supplied by increased proteid katabolism. It may be concluded, therefore, that the increased output of nitrogen observed in cats deprived of three-quarters or more of their kidneys is the result of inanition; no evidence was obtained that the kidneys directly influence nitrogenous metabolism.

Bradford found that dogs, after excision of part of one kidney, were apparently unable to pass a concentrated urine. The authors find, however, that under the same

conditions cats can still pass a concentrated urine and that its amount is not greater than normal Even after the second operation the urine is not excessive in amount or notably dilute Retention of nitrogen always occurred after the first operation, and in one animal after the second operation also **Analysis**, by Schryver's method, of the blood liver, and muscles showed by comparison with normal animals, a marked increase not only in the actual amount of residual nitrogen in these organs, especially the liver, but also in its percentage relatively to the total nitrogen

December 6 1906—"On the Transpiration Current in Plants" By Prof H H **Dixon**. Communicated by Prof J Joly, F R S

The adequacy of the theory which attributes the rise of water in trees during transpiration to the traction transmitted downwards in the water columns has been questioned by several different investigators These objections, which have been based on an erroneous view as to the effect of the presence of undissolved gas in the water-ways or of dissolved air in the water itself have already been disposed of A more recent criticism maintains that the resistance offered to the transpiration current by the conducting tracts of trees is so great that the forces generated in the leaves are inadequate to raise the water, and that even if these sufficed air-containing water could not transmit the tensions involved, and hence it is imperative to assume lifting mechanisms located in the water ways in order to account for the upward movement of water in trees

In the present paper it is pointed out that the advocates of this view have taken up their position partly owing to an overestimate of the velocity of the transpiration current but principally owing to an excessive evaluation of the resistance of wood to the flow of water

With regard to the methods employed by the critics of the cohesion theory to determine the velocity of the transpiration current the author points out that cut branches supplied with colour solutions draw up these solutions not only unretarded by the resistance of the lower parts of the stem but actually with the assistance of the atmospheric pressure There is also reason to believe that the velocity in the lower parts of the branches which is the velocity observed in these experiments, is greater than that in the more distal parts Hence the observation of the rate of the rise of the colour-solution, according to this method tends to give an exaggerated idea of the velocity of the water current in intact trees As to the second method employed for estimating the velocity of the current it is shown experimentally that the transpiration of isolated branches enclosed in desiccated chambers does not give a fair indication of the total amount transpired by all the branches of a tree but again tends to give excessive results This is evident immediately when we consider that the desiccated branch is able to draw on the water store of the whole tree

The paper also contains the record of numerous experiments carried out with the view of determining the resistance offered by the water-conduits of plants to the flow of water under various heads, and it is shown that the velocity which is directly proportional to the head is in the case of the yew between 7 cm and 9 cm per hour when the head is equal to the length of the transmitting piece of wood According to the recent criticism of the cohesion theory, to produce such a velocity would require a head equal to almost six times the length of the water conduits Hence the objection that to raise the sap in trees 150 metres high would require tensions approximating to 100 atmospheres, based as it is on this estimate, is without foundation In reality the cohesion theory would demand, if, indeed the excessive velocities before alluded to are assumed throughout the water ways of high trees, that osmotic pressures approaching 30 atmospheres should be available in the cells of the leaves Pressures of this magnitude have been observed in the leaves of less lofty plants

The discrepancy between the results of the observers quoted and those recorded in the paper are possibly partially due to the use of higher pressures by the former which tend to exaggerate the errors due to the inevitable clogging at the cut surfaces In this connection, a method is described by which this error may be eliminated when determining the amount of water transmitted through a cut branch

In conclusion, it is pointed out that not only is the cohesion theory in accordance with the most trustworthy observations, but the fact that other theories, both old and new, have to assume properties for the water-ways of plants which are either in the highest degree improbable according to received scientific views, or are even directly negatived by experiment, seems to support the theory by a process of exclusion

Chemical Society, January 17—Prof R Meldola, F R S, president in the chair—The relation between absorption spectra and optical rotatory power, part i, the effect of unsaturation and stereoisomerism A. W **Stewart**. A close relation is shown to exist between the general absorptive power of compounds and their molecular rotation, the substance having the greater general absorption having also the greater molecular rotation—Organic derivatives of silicon part ii the synthesis of *dl* benzylethylpropylsilicol, its sulphonation, and the resolution of the sulphonic derivative into optically active components F S **Kipping** *dl* Benzylethylpropylsilicol yields with sulphuric acid a mixture of sulphonic acids of which one has been isolated in the form of its ammonium salt This acid probably has the constitution

$SO_3H\ C_6H_4\ CH_2\ SiEtPr\ O\ PrEtSi\ CH_2\ C_6H_4\ SO_3H$,

and is the externally compensated compound The *d*-methylhydrindamine salt can be resolved by crystallising fractionally from aqueous methyl alcohol—The association of phenols in the liquid condition J T **Hewitt** and T F **Winmill** The authors have determined the surface energy of several liquids and find that the association of phenols is diminished or entirely inhibited by the presence of ortho substituents This effect of steric hindrance is also seen with the aromatic alcohols—A new mercuric oxychloride J T **Hewitt**. On allowing solutions of sodium hydroxide and mercuric chloride in sodium chloride to diffuse into one another, through a layer of sodium chloride solution of intermediate density, dark red crystals having the formula $Hg_6O_5Cl_2$ are deposited—Preparation of chromyl dichloride H D **Law** and F M **Perkin** Chromic acid is dissolved in concentrated hydrochloric acid, and sulphuric acid added in small quantities The chromyl dichloride formed is drawn off and purified by aspirating dry air through it and subsequent distillation—Oxidation of hydrocarbons of the benzene series H D **Law** and F M **Perkin** The hydrocarbons investigated were toluene the three xylenes mesitylene, ψ-cumene, and cymene In all cases varying yields of the monoaldehydes were obtained—The constitution of silver nitrite, a correction E **Divers**—Aromatic selenonium bases S **Smiles** and T P **Hilditch** Trianisyl- and triphenetyl-selenonium chlorides and some of their derivatives are described—The relation of colour and fluorescence to constitution A G **Green** A study of the phthaleins of phenol and quinol, which the author has had in progress for some time past has brought to light several facts strongly confirming the view that the coloured salts of these phthaleins have a quinonoid structure, thus rendering Silberrad's deductions as to the structure of these bodies unnecessary (Journ Chem Soc, 1906, lxxxvii 1787)—Tetraketopiperazine A T **de Mouilpied** and A **Rule**.—Transformations of highly substituted nitroaminobenzenes ii, *s*-tribromo-*l*-nitroaminobenzene Miss A E **Smith** and K J P **Orton**.—Resolution of tetrahydro-*p*-toluquinaldine into its optically active components T C **Beck** and W J **Pope**. By treating two equivalents of *dl*-tetrahydro-*p*-toluquinaldine hydrochloride with one equivalent of the ammonium salt of Armstrong and Lowry's *d*-$\alpha\beta$-bromocamphorsulphonic acid under appropriate conditions, a nearly quantitative separation of *d* tetrahydro-*p* toluquinaldine-*d*-$\alpha\beta$-bromocamphorsulphonate is obtained—Note on the theory of valency W **Barlow** and W J **Pope**. A reply to Chapman (Proc Chem Soc 1906, xxii, 320)—The condensation products of triacetic lactone with acetoacetic ester and β-aminocrotonic ester F N A **Fleischmann**.—Derivatives of multivalent iodine, part ii, action of heat on *p*-iodoacetophenone dichloride,

p-iodoacetanilide dichloride, and on the dichlorides derived from *o*-, *m*-, and *p*-iodotoluene W **Caldwell** and E A **Werner.**—Disalicylamide J **McConnan**—Benzoyl derivatives of *N*-methylsalicylamide J **McConnan** and M E **Marples.**—The velocity of reaction of bromine with some unsaturated acids in aqueous solution E **Barrett** and A **Lapworth.** The authors have been engaged in the examination of addition of bromine to some unsaturated acids in aqueous solutions in the hope of throwing some light on the mechanism of such reactions The results of experiments with cinnamic, benzylidenemalonic acid and β-bromocinnamic acids are described They appear in consistent with the view that bromine dissociates into ions before addition at a double linking, and seem to show that the ions of the acids, as well as the acids themselves, unite with bromine directly —Note on the molecular complexity of liquids A E **Dunstan** and F B **Thole** A criticism of Holmes's results (Journ Chem Soc, 1906 lxxxix, 1774)

Zoological Society, January 15 —Dr J Rose Bradford, F R S, vice-president, in the chair —A new monkey from the Ituri Forest, obtained during the recent Ruwenzori expedition Oldfield **Thomas**—The "bleating" or "drumming" of the snipe (*Gallinago coelestis*) P H **Bahr** The object of the paper was to prove that this phenomenon was produced by the tail-feathers of this species, a point which had been much disputed It was found that if the feathers were attached to a cork in a special manner, the peculiar bleating sound could be produced, and, furthermore, that only two feathers in this species were the active agents in producing the sound Observation proved that these two feathers were held in a particular manner in front of the others during the bird's flight in the breeding season Feathers of both male and female were found to bleat, a fact which had been borne out by numerous observers in the field These feathers were found to have a peculiar structure, differing materially from that of the other feathers in the tail Microscopically they differed, and the number of hamuli was found to be in excess of those found in other feathers The feathers of various exotic species had been experimented upon, and those of *G delicata G nobilis G frenata G paraguayae* in the New World, *G australis* and *G aucklandica* in the Antipodes, and *G solitaria* and *G megala* in Asia, had been found to produce musical sounds These feathers varied in structure, and consequently the sound produced differed accordingly The feathers of *G gallinula, G major*, and *G stenura* were not found to be musical —A collection of mammals from Annam sent home by Dr Vassal J L **Bonhote** Twenty-four species were enumerated, of which the following four were described as new —(1) *Nycticebus pygmaeus*, sp n, (2) *Lupaia concolor* sp n, (3) *Sciurus leucopus fumigatus* subsp n (4) *Funambulus rufigenis fuscus* subsp n Descriptions of seven new or little known species of marmoset monkeys from the Amazonian region Dr E A **Goeldi.**—Contributions to the knowledge of the systematic arrangement and anatomy of certain genera and species of Squamata F E **Beddard.**—A list, with descriptions of the new species of Pyralidæ collected by Mr A E Pratt in British New Guinea in 1902–3 G H **Kenrick.**

Royal Microscopical Society, January 16 —Annual meeting —Dr Dukinfield H Scott F R S president in the chair —The president delivered his annual address, his subject being the flowering plants of the Mesozoic age in the light of recent discoveries

Geological Society, January 23 —Sir Archibald Geikie, Sec R S, president in the chair —The geology of the Zambezi basin around the Batoka Gorge (Rhodesia) G W **Lamplugh** with petrographical notes by H H **Thomas.** This paper contains an account of the physiographical and geological structure of the hitherto undescribed country bordering the Batoka Gorge, which was investigated by the author in 1905 under the auspices of the British Association An account of the results obtained by the author appeared in NATURE of November 30 1905 (vol lxxiii, p 111)

DUBLIN

Royal Dublin Society, December 18, 1906 —Prof J A McClelland in the chair —The principal lines of the spark spectra of the elements Dr J H **Pollok.** The paper gave a collected table of the principal lines of all the common and rare elements arranged in order of their wave-lengths, and described a convenient method of conducting spectrographic analysis with gold electrodes by photographing the electrodes first with a long slit, and then sparking the solution under examination with a short slit, giving long gold lines, with short lines between of the element or elements under examination Photographs of a number of spectra were given, with conspicuous gold lines marked upon them at convenient distances, to aid in identification —The quantitative spectra of iron, aluminium, chromium silicon, lime manganese, nickel, and cobalt Dr J H **Pollok** and A J G **Leonard** This paper showed the progressive disappearance of the lines of these elements on dilution of their solutions, and gave tables of the residuary lines

January 15 —Prof Sydney Young, F R S in the chair —Radium and geology Prof J **Joly** (see NATURE, January 24, p 294) —Method of finding the absolute dilatation of mercury Prof J **Joly.** A mercurial barometer is raised in temperature by a steam jacket, and the change of reading observed The construction is simple and such as to eliminate errors of increased vapour tension An accuracy of 0 4 per cent is attained with ordinary care in observation

PARIS

Academy of Sciences, January 28 —M A Lacroix in the chair —The mineralogical constitution of the recent cone of Mont Pelée A **Lacroix** Conclusions drawn from a study of a series of specimens collected by M Guinoiseau during a recent ascent of the new cone —The superiority of the expenditure of energy arising from a flesh diet with respect to the expenditure arising from a diet in which foods of ternary composition predominate Consequences from the point of view of the general theory of food A **Chauveau** A dog was submitted to diets in which meat fat, and sugar respectively predominated The respiratory exchanges of the animal were studied both during work and at rest and the results shown graphically —The propagation of quasi-waves of shock P **Duhem**—Researches on the orbit of the comet 1819 IV (Blanpain), and on the possibility of the capture of this comet by Jupiter L **Lagarde** A re-calculation of Encke's results It would appear to be a case of the transformation of an orbit originally parabolic into an elliptic orbit of slight eccentricity but, owing to the small number of observations taken and their moderate accuracy there is still some uncertainty —The coefficients of development of the perturbation function Armand **Lambert**—Spherical functions Emile **Waelsch**—The representation by points of the most general equation of nomographical order 3 Maurice **d'Ocagne**—The curvature of the envelopes in the most general movement of a solid body in space G **Koenigs**—The calculation of the compressibility of gases in the neighbourhood of atmospheric pressure by means of the critical constants Daniel **Berthelot** Two methods of reduction are compared that of Van der Waals and the same modified by the author and these are compared with the experimental figures The author also criticises the method of reduction employed by M Guye, and condemns it —The solubility of carbon in barium and strontium carbides H Morel **Kahn** With barium the amount of carbon dissolved varied with the time of heating from 1 25 per cent to 6 2 per cent, and analogous figures were furnished by strontium carbide —Copper metaphosphate A **Auger** Cuprous metaphosphate is formed by the action of metaphosphoric acid upon copper at a red heat On cooling, the cuprous salt is decomposed into copper and the cupric salt —The causes which modify the estimation of fluorine in mineral waters P **Carle** It is pointed out that negative results for fluorides in mineral waters are commonly due to errors in manipulation and in particular the method used for separating the silica It is found that a solution of carbonic acid under pressure is capable of dissolving appreciable amounts of finely divided calcium fluoride Fluorides are nearly always a con

stituent of mineral waters.—A new method of estimating the halogens in organic compounds by means of the metal ammoniums: L. **Chablay**. In previous papers the author has given an account of the action of the metal-ammoniums on various organic haloid compounds, and in this work it was noticed that the whole of the halogen remained after the reaction combined with the alkali metal. This fact has been utilised as the basis of a very neat method for determining halogens in organic substances. Full details are given, and numerous analyses establishing the accuracy of the method proposed.—The condensed chromium sulphates: Albert **Colson**.—Some derivatives of hordenine: F. **Léger**. A description of the preparation and properties of the neutral tartrate, compounds with methyl and ethyl chloride, ethyl bromide and iodide, benzoyl and cinnamyl hordenine, and other derivatives.—Acetyl nitrate: Amé **Pictet** and Eugène **Khotinsky**. This substance has been obtained by dissolving nitric anhydride in acetic anhydride and separating by fractional distillation under reduced pressure. The nitrate detonates violently when suddenly heated, and hence had to be analysed by indirect methods. Towards aromatic substances acetyl nitrate acts as a nitrating agent of great power; benzene, toluene, anthracene, and thiophene being nitrated at temperatures below 0° C.—Ethyl benzoylglyoxylate: A. **Wahl**. Ethyl benzoylacetate in ether solution is submitted to the action of well dried nitrous fumes, and the product distilled under reduced pressure. The reactions of the new α-diketone with piperidine, hydroxylamine, o-phenylamine-diamine, semicarbazide, aniline, and phenyl hydrazine were studied.—The volume variations of the nucleus of the chromatic mass and of the cell in the course of the development of the pollen of *Nymphaea alba* and *Nuphar luteum*: W. **Lubimenko** and A. **Maige**.—Two new antelopes from Central Africa, *Cephalophus centralis* and *Cephalophus aequatorialis*: Maurice **de Rothschild** and Henri **Neuville**.—The affinities of the Bradypodidae (sloths), and in particular of *Hemibradypus mareyi*, with the Hapalopsidae of the Santacruzian of South America: R. **Anthony**.—The toxic products of the organism (muscular extracts): MM. **Charrin** and **Goupil**. The properties of an aqueous extract of muscle vary with the pressure under which the juices are expressed.—The interpretation of certain facts of coloured vision: Adrien **Guébhard**. A criticism of a paper on the same subject by J. P. Fortin.

THE SCIENTIFIC WORK OF WILLARD GIBBS

The Scientific Papers of J. Willard Gibbs. In two volumes. Vol. i., Thermodynamics. Vol. ii., Dynamics, Vector Analysis, Light, &c. Vol. i., pp. xxviii+434, price 24s. net; vol. ii., pp. viii+284, price 18s. net. (London: Longmans, Green and Co., 1906.)

THESE two handsome volumes are a fitting memorial to one who carved out for himself a very remarkable niche in the temple of scientific fame. With the exception of his one published book on statistical dynamics, we have in these collected papers practically all that Willard Gibbs put into form suitable for publication. Compared with the literary output of the leaders of science of the passing generation, this is a very limited contribution if judged only in regard to quantity. But the quality and far-reaching importance of Willard Gibbs's work place it on an eminence of excellence comparatively rarely reached. This remark specially applies to his great papers on the equilibrium of heterogeneous substances, which with his other papers on thermodynamics constitute the first volume of 434 pages. All are agreed as to the supreme importance of the thermodynamic memoirs, which give to their author a unique place among those who have done most to establish and develop the principles of this fundamental part of the doctrine of energy. It is not quite the same with the papers which form the second volume, of 284 pages, although in these also the author's characteristic qualities of mind show themselves. There is always an originality of view and a logical severity of treatment which indicate that the author has well digested his material before putting it in printed form before the eye of the public. Nevertheless, even if we do not consider the contents of vol. ii. as attaining the same high average of excellence as the contents of vol. i., their comparative brevity makes good the claim that in Willard Gibbs we had a writer and thinker of very exceptional merit.

Unlike most young scientific men, Willard Gibbs was in no hurry to publish, his earliest papers dating from 1873, when he was thirty-four years of age. The second of these papers, that on thermodynamic surfaces, became speedily known to the scientific world through the pages of Maxwell's "Theory of Heat", and Maxwell was himself the first to construct a model of the volume-entropy energy surface. Copies of this model were distributed by Maxwell evidently with a certain amount of playful mystery, for each recipient thought that he was the happy possessor of one of (at most) three. The writer knows of six at least, and possibly there are more. We also owe to Maxwell a very clear, brief statement of the essential feature of the great papers on the equilibrium of heterogeneous substances. In spite of this, however, the immense value of these memoirs came to be fully recognised only very gradually, in many instances after important results had been obtained independently by later investigators. In 1892 Ostwald brought out a German translation which was reviewed at the time in these columns (vol. xlvi., p. 245). A French translation followed in 1899, and now at length we have these epoch-making papers reproduced so as to be accessible to everyone. In their new dress they cover about a third more pages than in their original form in the Transactions of the Connecticut Academy of Arts and Science, and the larger type and broader page impart a dignity worthy of their high position in the literature of thermodynamics.

The first volume closes with some unpublished fragments which were intended to form a supplement to the "Equilibrium of Heterogeneous Substances." Only two of a list of nine subjects are touched upon, and one cannot but have a feeling of deep regret that the distinguished author was unable to carry out his project.

The second volume contains twenty-one distinct papers and articles arranged under four headings. In a paper on the fundamental formulæ of dynamics, Gibbs suggests using δx, δy, δz instead of the usual δx, δy, δz, and shows that for certain problems the modification is of advantage. The second paper is a single page abstract from the Proceedings of the American Association for the Advancement of Science on the fundamental formula of statistical mechanics, and is of interest as showing the trend of his thinking sixteen years before the publication of his great work on the subject. Eight papers then follow on vector analysis and multiple algebra. The first of these is the reprint of the famous "not published" pamphlet which was printed for private circulation in 1881-4, and it is in reply to certain criticisms of this pamphlet that some of the succeeding papers were written, chiefly as letters to NATURE. Willard Gibbs received his first impulse towards the study of vector methods from Maxwell, who used the quaternion notation in his "Electricity and Magnetism." Not caring for the quaternion approach for reasons which are explained fully in his controversial articles, he elaborated a notation of his own for the frequently recurring functions familiar to students of Hamilton and Tait. What gives Gibbs's method its character is, however, his "dyadic" notation for the linear vector function. Unlike Hamilton's ϕ, which has, so to speak, only one hand to grip the operand which follows, Gibbs's dyadic has two hands, with one of which it may grip forward and with the other backward as occasion may offer. It cannot, however, grip with both at once, so that the double-handedness is only apparent. Moreover, it is only in its expanded form that the dyadic is able thus to clerk on to an operand on either side. When, as is frequently the case, the Hamiltonian function ϕ is used, the method becomes identical with that of quaternions.

A very readable paper is that on multiple algebra which Gibbs originally delivered as his presidential address before the mathematical section of the

American Association for the Advancement of Science. Here we find expounded with rare clearness and happy illustration the essential principles of multiple algebra. We can imagine many aspiring mathematicians getting from this article a strong impulse towards the study of a subject the fundamental principles of which are at times almost intuitive, but the working out of which in detail is full of difficulties and pitfalls to trap the unwary.

Under the heading of "The Electromagnetic Theory of Light" there are five papers, all important contributions. They show the sufficiency of the electromagnetic theory to explain dispersion and double refraction, whereas the elastic solid theory of Green could not be reconciled with experimental facts. The elastic theory was, mathematically speaking, rescued from its distressed condition by Kelvin when he imagined the contractile ether, and in regard to this Gibbs points out that, although it explains many phenomena as simply as the electromagnetic theory, it fails to give a satisfactory explanation of dispersion.

Finally, there are six miscellaneous papers, partly reviews and biographical notices. The closing sentence of his notice of Clausius, in which reference is made to the great number of papers published by the eminent German, might by a slight modification be applied to himself:—

"Such work as that of [Gibbs] is not measured by counting titles or pages. His true monument lies not on the shelves of libraries, but in the thoughts of men, and in the history of more than one science."

The papers have been edited with great care by Henry Andrews Bumstead and Ralph Gibbs van Name, and the former, in the biographical notice prefixed, discusses with knowledge the scientific work done by Willard Gibbs, and gives a clear-cut picture of the man himself. A portrait forms the frontispiece to vol. i.

TECHNOLOGY OF SOAPS AND CANDLES.

Modern Soaps, Candles and Glycerin. By L. L. Lamborn. Pp. xx+688. (New York: D. Van Nostrand Company; London: Crosby Lockwood and Son, 1906.) Price 30s. net.

THIS is a work intended primarily for the soap manufacturer, and more especially for the American beginner in the art and craft of soap-making. The author finds, he tells us, that the industry has hitherto been indebted for its technical literature to those who can write, but have little worth telling. To remedy this state of things he, a practical man, to practical men sends forth the present volume.

On the whole the effort is a successful one, though the book has defects. Let us summarise these at the outset. Heavy both in style and in avoirdupois, and printed on glazed paper that is very trying to the eyesight, the work is by no means an attractive one to read. There is much tedious repetition, and an unnecessary amount of technical slang is employed. For example, on p. 340 we are directed to "kill the rosin as already described, but leave the soap open on salt alone, with entire absence of strength." The book is quite "practical" enough to dispense with kettle-room jargon. Generally, it suffers from excessive verbiage, the author has a tendency to write round his subject as well as upon it.

Now let us see what there is of value in the book. The various operations of soap manufacture are fully described, about two-thirds of the available space being devoted to this branch of the subject. Two introductory chapters outline the history and principles of soap making, then come three others, dealing respectively with the raw materials, their purification and their chemical characters; these are followed by one describing the mechanical equipment of a soap factory, and next by the sections which discourse of the various kinds of soap and the processes involved in their production. The treatment is eminently practical, and, so far as the reviewer can judge, entirely trustworthy. Many useful tables, formulæ, and recipes are embodied in the text, a good section on essential oils and soap perfumery is interpolated, and a large number of illustrations of apparatus are included. These last are naturally, figures of American machinery almost exclusively; they constitute quite a feature of the work.

In connection with "medicated" soaps, the author is sceptical about any appreciable curative effect being rightly attributable to the medicament or disinfectant incorporated with the soap. The proportion of active ingredient is often very small, and under ordinary conditions of use the time of contact with the skin is but short, so that the scepticism is probably justified. Such curative property as the soaps may possess is, the author thinks, inherent in the detergent itself; the remedial value lies in the mechanical action of cleansing rather than in any specific bactericidal or antiseptic effect of the incorporated substance.

In the section dealing with the manufacture of candles there are two points of special interest. One of these relates to a long-standing problem of chemical technology, namely, how best to utilise the by-product oleic acid as a source of candle material. This acid forms a large proportion of ordinary fats, but, being a liquid, is not suited for the production of candles. It is possible, however, to convert the oleic acid into solid substances (elaidic acid, hydroxystearic acid), which can be so used, but until recently the expense and the smallness of the yield have prevented the satisfactory utilisation of the by-product in this way. The author outlines the latest modification of the process for transforming oleic acid into hydroxystearic acid; it is asserted that from 85 per cent. to 95 per cent. of the former can now be obtained as the solid product, instead of only 30 per cent. as previously produced. Sulphostearic acid and stearolactone are obtained by dissolving the oleic acid in petroleum and treating the solution with strong sulphuric acid; the first gives hydroxystearic acid on hydrolysis with steam, the stearolactone is re-con-

verted into oleic acid and again subjected to the action of sulphuric acid. The author, unfortunately, says nothing definite about the vital matter of expense, but as far as the complete recovery of the by-product is concerned the process now leaves little to be desired.

The other matter of interest is the Twitchell method of decomposing fats into their constituent fatty acids and glycerin. This is effected by boiling the fat with water and a small quantity—about 1 per cent.—of sulphobenzenestearic acid. On standing, the products of the reaction separate into layers of fatty acids and glycerin of a relatively high degree of purity. Not only in candle-making, where it is now largely used, but in soap-making, the process is claimed to be economically superior in several respects to the time-honoured method of saponification with alkali hitherto universally adopted. It gives a greater yield of glycerin, the cost of recovering the glycerin is smaller owing to the much greater purity of the menstruum, there is economy in the cost of material, since soda-ash can be used instead of the more expensive caustic soda for converting the fatty acids into soap, and, finally, the necessary mechanical equipment is simpler. Whether or not with these advantages the Twitchell process will eventually supersede the historic alkali method of soap-making remains to be seen; the indications are that it may well do so. Meanwhile, the remarkable steatolytic action of the sulpho-aromatic fatty acids, on which the process depends, is worthy of note from the scientific point of view. One explanation of the ease with which fats are resolved into their constituents by these compounds assumes it to be due to the emulsifying power of the sulpho acids, but the matter requires further investigation.

The most approved methods for the recovery of glycerin are fully described, and the work closes with a chapter on the chemical examination of raw materials and factory products.

In view of recent events in this country, it is interesting to read that in the United States, where other kinds of "trusts" seem to flourish, there is but little "cooperative control of production" in the soap industry. On the contrary, there is a marked tendency towards self-sufficient independence among the individual producers. The author's reason for this is that, whilst control of the raw material and of the facilities for transport are two essential factors in organising a successful "combine," these conditions are largely absent in the production and distribution of soap.

"The chief raw material is obtainable wherever meat is eaten, and the market exists wherever cleanliness is appreciated."

Possibly more than anything else it was the difficulty of monopolising the supplies of raw material that recently enabled the individual producers in this country to maintain the "tendency towards self-sufficient independence" which the author notes in the case of soap-makers in the United States.

C. SIMMONDS.

SOME PROLEGOMENA TO THEOLOGY.

Völkerpsychologie: eine Untersuchung der Entwicklungsgesetze von Sprache, Mythus und Sitte. By Wilhelm Wundt. Zweiter Band. Mythus und Religion. Erster Teil. Pp. xi+617. (Leipzig: Wilhelm Engelmann, 1905.) Price 14s. net.

THIS is the first part of the second volume of Wundt's important work, and it deals in three long chapters with imagination, imagination in art, and imagination in the formation of myths.

The first chapter defines imagination, and points out its chief characteristics, *e.g.* that it is intuitive in its working, and does not deal with the products of the understanding, that it is creative, and that it is spontaneous or involuntary. The author claims that experimental analysis reveals its mode of operation as a subjective condition of all our perceptions in space and time. More especially the illusions in space-perceptions are discussed by which, *e.g.*, a tetrahedron as represented on paper may appear to face the spectator in two quite different ways according to the position of the point fixated, and again in regard to time it is pointed out how the imagination of itself supplies the measure into which a succession of musical notes of precisely the same emphasis and length is fitted, so too with speech-rhythm. Sensations of light, colour, movement, and the like are next discussed, and the author reaches the conclusion that there are two main principles at work in imagination, the one *vivifying apperception*—the spectator so projecting himself into the object that he feels himself at one with it, and the other *the power of illusion or imagination to heighten feeling*. The writer now passes to child-psychology, and analyses imagination in children as it may be observed in their play, their fairy tales, and their attempts at drawing, and in comparing the products of the artistic faculty in children and in savages he emphasises the two points that neither savages nor children, as a rule, copy objects before them, but recall what they have seen, and that both prefer objects in which they have an immediate interest, generally men and beasts.

The second chapter deals with imagination in art. Wundt believes that it is utterly idle to inquire what form of art arose first, that in the most primitive races we find the beginnings, not only of the musical arts (including both dance and song) but of the graphic arts as well. Into the details of the chapter, which discusses the whole range and development of the graphic and musical arts, we cannot now enter. The author inquires among other things why in early art beasts are drawn more truthfully than men, and notes that as early art is generally based on recollection it exhibits a face view of human beings but a profile view of beasts. The discussion of *Stilisierung* on pp. 186–8 is interesting, and the gradual progress exhibited of the alligator motive, though perhaps not convincing to the ordinary man, is as possible as many other things in anthropology.

A suggestive treatment, too, may be found of the different effects produced by portrait and statue (p 274), and of the reasons that may be given for the differing shapes of Egyptian and Greek temples In dealing with song, the author contests the view of Preuss that all work-songs were originally charm-songs He strongly opposes the theory of Jacob Grimm that the fairy-tale is a degenerate nature-myth, his own view with regard to the relative position of the fairy-tale, the nature-myth, and the epic appears to be that the epic has two sources, traditions of actual heroes on the one hand, and the despised fairy-tales on the other, and that it has not as its immediate preparation any such high-flown theogony and cosmogony as the supporters of the Grimm theory allege He discusses, too, the views of Usener, the foremost representative of the nature-myth hypothesis, who regards Thersites, for example, as being originally a god, and who sees in the struggle between Thersites and Achilles a variation of the old story of the struggle between summer and winter

The third and last chapter opens with a contrast between the historical and the psychological treatment of mythology, and the author claims that psychology is of more importance in dealing with myth than in dealing with speech, which after all is, in the narrower sense, a psychophysical function His discussion of the various types of theory the naturalistic, the animistic, the theory of analogy and the like, if full and adequate, is a little hard to follow The author is strongly opposed to the hypothesis that myths have all arisen in one period and one country

"If Anthropology has established anything," he writes, "it is this, that the qualities of human imagination and the feelings and emotions that influence the working of the imagination agree in their essential features in the men of all zones and countries, and that therefore no migration-hypothesis, going far beyond the bounds of possible proof, is needed to explain the similarity of certain fundamental ideas in mythology, while on the other hand the perpetual differences of these products of the imagination, depending as they do on natural surroundings, race and degree of civilisation, in many ways point directly to an autochthonous origin"

The cream of Wundt's own psychological theory on the matter seems contained in p 579, mythological personification he regards as only a heightened form of what writers on æsthetics call *Einfuhlung*, "a form in which the whole personality in its momentary condition of consciousness, together with the after effects of earlier experiences which enter into this, passes over to the object" So we have only to do with a modification of that general function without which the object could not exist for us at all, namely, apperception

Space fails us to discuss the topics of the closing pages, the distinction drawn between myth and poetry, the mutual influence of myth and poetry, their relations to speech, and so on The second part of this volume will be concerned with the problems that surround the connection between myth and religion. The full significance of Wundt's contribution to his present subject can hardly be realised until that part has appeared, and for this and many other reasons its speedy publication will be welcome to the numerous readers whom this instalment has doubtless interested and attracted.

COAL MINING

The Principles and Practice of Coal Mining By James Tonge Pp viii+363 Illustrated (London Macmillan and Co., Ltd, 1906) Price 5s net

UNTIL the year 1866, when Sir Warington Smyth wrote, for Weale's excellent series of rudimentary handbooks, his little book on coal-mining, the art of mining was in the trammels of empiricism, but since that date progress has been rapid Indeed, the tendency of the times is now towards a higher standard in mining as in all branches of technical education Greater efficiency is consequently now demanded of candidates for the Board of Education examination in the principles of mining, and for the examinations for certificates as colliery managers and under-managers In order to meet these conditions there has been of recent years a steady output of new elementary mining text-books Many of these are excellent, but not one of them is presented in so attractive a form as the latest addition to the list by Mr James Tonge Well printed, tastefully bound, and copiously illustrated, it gives in concise form an accurate view of the subject of coal-mining, together with such information regarding collateral science as is essential for the elementary student

In his treatment of the subject, the author wisely has followed closely the logical and natural order laid down by the late Sir Clement Le Neve Foster for the Board of Education syllabus General ideas are first given regarding the occurrence of coal and the methods of search The sinking of shafts and the working of coal then receive attention The means of supporting the roof and sides of underground excavations, and the conveyance of the coal to the shaft and thence to the surface, come next Other chapters are devoted to the important operations of keeping the workings free from water and of supplying them with fresh air and light The volume concludes with chapters on the preparation of coal for the market, and on the accidents and diseases incidental to the miner's calling, with some brief notes on the laws regulating mining in this country

These varied subjects are dealt with in a thoroughly practical manner, and although necessarily brief, the descriptions are well up to date We note, for example, an interesting account of the Parsons turbo-fan A screw fan, used in conjunction with a compound steam turbine, at a colliery at Wylam-on-Tyne exhausts air from the pit and discharges it into the atmosphere through a conical outlet The diameter of the fan is 5 feet, and it passes 120,000 cubic feet per minute at 2-inch water gauge, running at a speed

of 2000 revolutions per minute. The steam pressure at the turbine is 70lb per square inch, and the exhaust steam is condensed. At the Hulton Colliery Company's Deep Arley Pit, with which the author is connected, a turbine-driven fan has recently been erected. The plant consists of a screw propeller fan 9 feet 6 inches in diameter, driven direct by a steam turbine. The efficiency of the fan varies from 50 to 60 per cent., and although this is low compared with that claimed for other fans, the economy of the plant, or in other words the steam consumed per useful air horse-power output, compares favourably with that usually obtained with centrifugal fans driven by high-class reciprocating steam engines. An illustration of the plant is given. Throughout the book the illustrations are adequate, and in many cases very good, the only exception being Fig. 111, of a coil clip for endless rope haulage, which appears to be incorrectly drawn.

AMPHIPODOUS CRUSTACEA

Das Tierreich. 21 Lieferung. Crustacea Amphipoda, I., Gammaridea. By the Rev. T. R. R. Stebbing, F.R.S. Pp. xxxix+806, 127 figures in text. (Berlin: R. Friedländer und Sohn, 1906.) Price 48 marks.

READERS of Stevenson may possibly remember that when the hero of "Catriona" took leave of Alan Breck on Gillane Sands and turned to meet his pursuers his attention was caught, in the solitude and silence of that "unchancy" place, by "the sand-lice hopping nimbly about the stranded tangles." One might search far through the fields of literature before finding another mention of the amphipodous Crustacea. Their small size, the aquatic habits of the majority, and the fact that they are neither immediately useful nor directly harmful to man, combine to withdraw them from popular observation, while even to many who claim the title of naturalist they are known only by name. Yet the student who attempts to gain some knowledge of this group of animals is likely to be bewildered at the outset by the almost infinite variety of specific differentiation which they present, no less than by the overwhelming mass of technical literature in which their peculiarities are recorded.

It is true that more or less comprehensive systematic monographs and summaries of what might be called the "minor morphology" of the group are not wanting. In his "Catalogue of the Amphipodous Crustacea in the British Museum," published in 1862, Mr. C. Spence Bate attempted a revision of all the forms then known, and thereby lightened considerably the task of subsequent workers, if sometimes also adding not a little to their perplexities. Later monographs, such as those of Boeck, Bovallius, Sars and Mayer, have dealt only with single subdivisions of the order or with the Amphipoda of restricted geographical areas. In 1888, however, Mr. Stebbing's monumental report on the Amphipoda of the *Challenger* Expedition not only described a larger and more varied material than had been at the disposal of any previous writer, but gave an exhaustive and critical analysis of the earlier literature, the like of which is available for very few other groups of animals.

When, therefore, it was announced that Mr. Stebbing had undertaken to prepare a revision of the Amphipoda for the "Tierreich," every carcinologist anticipated that its publication would mark an epoch in our knowledge of the group. The present volume of more than eight hundred pages contains only the first part of this work, dealing with the Gammaridea, the largest of the three legions (or suborders) into which the order is divided. It is in every way worthy of Mr. Stebbing's high reputation. The whole field of existing literature has been explored with painstaking minuteness (extending to the collection and recording of typographical errors), and an unrivalled experience in dealing with this group of animals has been brought to bear on the task of interpreting and criticising the descriptions of previous authors.

As Mr. Stebbing explains in the preface, the work as originally planned included all species described up to the end of 1898, but publication was unavoidably delayed. A supplement has, however, been added which enumerates, without describing, the new species and genera established up to the end of 1905. Excluding those dealt with in the supplement, the number of species accepted as valid is 1076, while 257 others are mentioned as doubtful. They are distributed among 304 accepted and nine doubtful genera and forty-one families.

In a work like the present, questions of nomenclature inevitably come to the front, and even those zoologists who deprecate unnecessary interference with established names will admit it to be desirable that in an authoritative revision of a group of animals an effort should be made to settle the nomenclature on a stable basis. Mr. Stebbing has devoted much attention to this point, and his decisions will in most cases be accepted as final by the majority of students. We may regret, however, that he has not seen his way to mitigate the severity of his interpretation of the rule of priority in one or two cases where it seems to introduce, instead of removing, confusion. As Mr. Lydekker pointed out some time ago in a letter to NATURE (vol. lxxi., p. 608), the transference of old and well-known generic names to other genera may often be seriously misleading. With regard to one such change adopted in the present work, Canon Norman recently expressed the opinion that, "considering the inadequate description of the genus Podocerus and its erroneous use for nearly one hundred years, the name ought to be excluded from an altered use." This opinion, coming from one of so wide experience in systematic zoology, will find many supporters, at least among those who think that the animals themselves are more profitable objects of study than their names.

Mr. Stebbing's volume will remain the standard work of reference on the Gammaridea for a very long

time to come, and he has earned the gratitude of all students of the group by its publication. The editors of "Das Tierreich" are to be congratulated on the latest addition to the exceedingly useful series of monographs issued under their direction.

W. T. C.

OUR BOOK SHELF

Incubation, or the Cure of Disease in Pagan Temples and Christian Churches. By Mary Hamilton. Pp. 223. (London: W. C. Henderson and Son; Simpkin, Marshall, Hamilton, Kent and Co., 1906.) Price 5s. net.

"IN the ancient science of divination, four working methods were commonly practised. Revelations of the future were deduced from natural portents, from the flight of birds, from the entrails of sacrificial victims, or from dreams. Incubation was the method by which men sought to entice such dreams." These sentences from the introduction indicate the substance of this work. The book is divided into three parts:—(1) incubation in pagan temples, *e.g.* the cult of Asklepios at Epidauros, Rome, Athens, &c., and at the Oracles, Amphiaraios, and others; (2) incubation in Christian churches during the Middle Ages; and (3) the practice of incubation during modern times in Italy, Austria, Greece, and the Greek islands. Translations are given of the various stelæ which describe the cures wrought and the methods employed in procuring them. The book forms a useful summary of the subject, valuable both to archæologists and to historians of medicine.

Manual of Wireless Telegraphy. By A. F. Collins. Pp. x+232. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1906.) Price 6s. 6d. net.

THE present writer ventured to suggest, in an article in NATURE a short time ago, that with the publication of a really standard book on any particular branch of electricity the issue of further literature on the same subject should cease. If this recommendation had been adopted the present volume would never have seen the light. It does not profess to be anything more than a manual specially adapted for those who are, or desire to become, wireless telegraph operators. There are already numerous books covering almost identically the same ground, and we are of opinion that the useful information contained in any of them could be much more effectively learnt in an hour's practical instruction. Compared with other books of its kind, it may be pronounced a favourable specimen. The style, though a trifle too American for our taste, is simple, and the diagrams are numerous and clear. The illustrations are also plentiful and well reproduced. A list of stations and ships equipped on the various systems forms a distinct feature of the book which will probably remain up to date for a few weeks longer.

M. S.

Catalogue of the Lepidoptera Phalaenae in the British Museum. Vol. vi., Noctuidæ. Pp. xiv+532; pls. xcvi-cvii. (London: Printed by order of the Trustees, 1906.) Price 25s.

THE present volume is the third of those devoted to the great family Noctuidæ, and includes the subfamily Cucullianæ, with 111 genera and 693 species, a considerable number of both genera and species being described as new. In addition to the coloured plates there are 172 plain illustrations in the text, generally representing the body and left wings of a specimen, the right wings being denuded of scales to show the neuration. To the right of this again is the outline of the thoracic crest and head in profile, the latter showing an antenna, eye, palpus, &c. The first text figure, however, represents the larva of *Cucullia verbasci*. Opposite p. 2 is a large table, showing the relationship of the genera regarded as belonging to the Cuculllanæ with one another. The general arrangement and character of this volume differ little from those which have preceded it. Full tables are given of genera and species, and the descriptions are quite sufficiently long for most practical purposes. Brief notices of larvæ and food plants are added, when known.

It is very creditable to all concerned that this important work should be carried on so steadily, a volume appearing about every two years. It may be interesting to notice the dates of the prefaces of each of the six volumes already published:—Vol. i. (Syntomidæ), September 30, 1898; vol. ii. (Arctiadæ: Nolinæ, Lithosianæ), January 20, 1900; vol. iii. (Arctiadæ: Arctianæ, and Agaristidæ), June 20, 1901; vol. iv. (Noctuidæ: Agrotinæ), June 20, 1903; vol. v. (Noctuidæ: Hadeninæ), February 24, 1905; vol. vi. (Noctuidæ: Cuculllanæ), November 1, 1906.

Die meteorologischen Elemente und ihre Beobachtung mit Ausblicken auf Witterungskunde und Klimalehre. By Otto Meissner. Pp. vi+94; with 33 illustrations. (Leipzig u. Berlin: B. G. Teubner.)

THIS very useful text-book, intended for higher schools and for self-instruction, forms part vi., vol. ii., of the collection of scientific treatises published by O. Schmeil and W. B. Schmidt. It explains the physical laws necessary for clearly understanding meteorological processes and apparatus, and contains valuable footnotes, together with the derivation of all technical terms employed in the text. Many points, such as the difference between periodical and non-periodical oscillations of meteorological elements, "variability" of temperature, the use of the cloud-mirror, &c., which are frequently puzzling to observers, and are generally only dealt with in treatises of greater pretensions, are made quite clear by means of examples. We recommend the perusal of the work to any meteorological students who are acquainted with the German language.

The Treatment of Diseases of the Digestive System. By Prof. Robert Saundby. Pp. viii+133. (London: Charles Griffin and Co., Ltd., 1906.) Price, 3s. net.

THIS unpretentious little book will serve to bring before the practitioner the salient points in the diagnosis and treatment of diseases of the digestive tract. The dose of bismuth in many cases might be larger; useful drugs such as salol, bismuth salicylate, and ipecacuanha are not mentioned, and no precautions are detailed in the use of thymol in ankylostomiasis. Otherwise the teaching throughout seems to be sound and commonsense.

The Plants of New South Wales. By W. A. Dixon. Pp. xxxiv+322. (Sydney: Angus and Robertson, 1906.) Price 6s. net.

THIS is a handy little book providing a compact guide for naming flowers in the field by means of analytical tables on similar lines to Gremli's well-known flora of Switzerland, but localities are omitted. The author lays stress on the extensive use made of vegetative characters for identification, with which there can only be entire agreement so long as the characters are determinative.

While a condensed guide of this kind is of the greatest service, for carrying about, sooner or later the botanist is sure to require a flora giving fuller

descriptions The author has prepared for this contingency by providing references under each genus to the "Flora Australiensis" and the "Flora of New South Wales," and has arranged his system and nomenclature according to the last named Ferns and fern allies are included, but of monocotyledons the families of rushes, sedges, and grasses are left out

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications]*

Magnetic Storm and Aurora on February 9-10

A MAGNETIC storm was recorded at the Kew Observatory (National Physical Laboratory) on the afternoon of February 9 and early morning of February 10 larger than any that has occurred since October 31, 1903 The curves were slightly disturbed during the whole of February 9, but the storm may be regarded as commencing with a rapid movement of a few minutes of arc in the declination needle at 2 15 p m, with a synchronous sudden rise of 45 γ (1 γ=0 00001 C G S) in the horizontal force The storm lasted an unusually short time, being practically over by 3 a m on February 10, but several large rapid movements were recorded The largest declination movement occurred between 8 19 p m and 8 45 p m on February 9 During these twenty-six minutes the needle moved 57′ to the west and then 73′ to the east, the extreme westerly position being reached at 8 34 p m The most easterly position during the storm was reached at about 10 55 p m, when the trace was off the sheet for a few minutes The range during the storm actually shown on the sheet was 1° 38′ Between 1 13 a m and 1 45 a m on February 10 the needle moved steadily, without sensible oscillation, to the west, this movement reaching 1° The rate of movement was practically uniform from 1 13 a m to 1 33 a m, when it accelerated so suddenly that the curve resembles two straight lines inclined at a finite angle

In the case of the horizontal force, the force fell more than 355 γ between 8 25 p m and 8 33 p m on February 9 when it went off the sheet for a few minutes Between 8 40 p m and 8 49 p m it increased fully 240 γ The total range during the storm exceeded 480 γ

The vertical force, though less disturbed than the other elements, showed a range of 325 γ, the highest and lowest values being attained at 6 25 p m on February 9 and 1 48 a m on February 10 respectively The most rapid change took place between 8 25 p m and 8 42 p m on February 9 The storm was doubtless associated with the aurora, which seems to have been widely observed on the evening of February 9 CHARLES CHREE

AN unusually beautiful display of aurora borealis was seen here (51° 56′ N lat, 2° 35′ W long) between 6 30 p m and 11 p m on Saturday evening, February 9 At about 6 30 p m I became aware that the north-western sky, instead of darkening after sunset, was becoming lighter and the quivering upward rays showed that it was the northern lights The aurora was at its best between 8 p m and 9 30 p m, stretching half across the northern heavens from Cetus to Leo, from the horizon upwards towards the zenith, some of the curved flashes reaching to Jupiter

This aurora was characterised by the brilliant soft whiteness of its light, occasionally tinged with pale green which filled the north-western and northern sky from the horizon to a considerable elevation, from which at times long rays shot up, but more generally the lights appeared as curved, wavy bands rushing up to the zenith, and hanging there for a few seconds as white, cloudy patches in the clear sky among the brighter stars Between 8 45 p m and 9 15 p m the colour about Ursa Major and Leo was a dull, faint red The aurora was not watched after 11 o'clock, but by that time it had greatly diminished in brilliancy, and the sky was becoming cloudy

I may add that for some weeks I have been noting the sun-spots, of which lately there have been a considerable number, and on the morning of February 9 one near the middle of the sun's disc was so large that I afterwards saw it with the naked eye through smoked glass

T A

Dadnor, near Ross, Herefordshire, February 11

The Flight of an Elongated Shot

WOULD any reader of NATURE kindly enlighten me on the following points in the theory of projectiles?

(1) Whether one is right in supposing that a bullet or shot of the modern pointed cylindrical form, when fired at any angle of elevation *in vacuo*, would preserve the original direction of its axis of rotation so that at the end of its flight its long axis would be considerably inclined to its line of flight

(2) Whether a similar shot fired through the air would be acted upon by a couple tending to produce rotation about an axis perpendicular to the plane of the trajectory, the magnitude and direction of this couple depending upon the form of the projectile and the position of its centre of gravity, a zero value being possible and whether the effect of this couple would be to produce rotation about an axis in the plane of the trajectory and perpendicular to the long axis of the shot so that the point of the projectile would be deflected downwards and to the right or left

(3) Whether if the above suppositions are correct any successful attempts have been made to keep the long axis of the shot tangential to its trajectory during the whole course of its flight by giving it a particular form, and varying the density of its parts in a particular way

P D STRACHAN

Philippolis, Orange River Colony

THE answer to proposition (1) is best given for the most general case A body projected in any manner in a field of gravity *in vacuo* will move so that the centre of gravity (C G) describes a parabola while the body moves about the C G so that to an observer seated at the C G the body has the motion described by Poinsot in which the momental ellipsoid rolls on a fixed plane The normal to this plane is the axis of resultant angular momentum and this axis preserves a direction fixed in space while the body moves about it When this axis coincides with a principal axis the body appears to be spinning steadily about the axis but a closer observation reveals always a precessional and nutational motion

The question in the limited form of proposition (1) presupposes a body of perfect uniaxial symmetry spun accurately about its axis but such a condition cannot be realised in practice any more than it is possible to balance a pin on its point and so it is better to replace this ideal state of proposition (1) by the penultimate state in which the spinning body like a sleeping top upright has steadiness almost perfect

With this limitation the axis of an elongated shot would move parallel to itself on the whole if fired in a vacuum as stated in proposition (1) But if fired in air as in proposition (2) a couple arises as soon as the axis is oblique to the direction of motion tending to place the axis of an elongated shot broadside to its motion and at right angles to the tangent of the trajectory and this couple acting on the rotating shot will cause the axis to precess about the tangent Even in the absence of air resistance and gravity the resulting motion is of great complexity where the body is influenced by the stirring up of the surrounding medium and the special case of a figure of revolution discussed by Kirchhoff and Clebsch is more complicated than the gyroscopic motion of a top spinning in a smooth cup

The problem defies analysis when gravity and air resistance are taken into account all we can say is that the frictional drag damps the nutation and causes the axis of the shot to follow the tangent of the trajectory very closely the point of the shot being seen to be slightly above the tangent and to the right with a right handed spin The conditions of proposition (3) are secured then

independently of any supposition or condition of shape and density of the shot, provided the spin imparted by the rifling is suitable, and that the trajectory is not curved too much A G GREENHILL

The Atomic Weight of Nickel

In a paper on the absorption of Röntgen rays (*Journal de Physique*, p 653, 1901) M Benoist shows the connection between the transparency to X-rays of elementary substances and the atomic weight of those substances by means of a curve, which in general exhibits a fall of transparency with a rise in the atomic weight of the absorbing substance In continuing investigations on secondary X-rays, Mr C A Sadler and I have found that by replacing Benoist's primary beam by secondary beams from different substances, curves are obtained similar to that got by using a beam direct from an X-ray tube, except in the region of atomic weights near to that of the radiator In those regions a strongly marked deviation occurs, showing a special transparency to the secondary radiation from a substance, by a sheet of the same substance, and a less strongly marked abnormal transparency of those substances with atomic weights differing little from that of the radiator Also the nearer on the same side the atomic weight of the absorbing substance is to that of the radiator, the greater is the deviation from the normal transparency This effect does not indicate that the secondary rays as emitted by the atoms of a substance are specially penetrating, but simply that in emerging from the interior atoms to the surface a selective absorption has occurred, leaving the remainder specially penetrating to further layers of the same substance and to a less extent to substances of neighbouring atomic weights This is not a property of secondary rays alone, for experiments on primary beams which have passed through thin sheets of metal show the same effect

In making such experiments on a number of metals it was found that the radiation from nickel was much more abnormally penetrating to copper than to iron, indicating a proximity of atomic weight to that of copper On the other hand, when cobalt was used as a radiator the rays were much more abnormally penetrating to iron than to copper, indicating that the atomic weight of cobalt is nearer that of iron than of copper

The two experiments together furnish what seems to us to be the strongest evidence, based, not only on empirical law but on theory, that the atomic weight of nickel is not slightly less than that of cobalt (the accepted values are Ni 58 7, Cr 59), but is considerably greater

The evidence however, does not end here In a paper on secondary Rontgen radiation I suggested a method of determining atomic weights—based on the fact that the radiation is purely an atomic property—by graphically plotting the absorbability of the secondary radiation proceeding from different elements subject to X rays and the atomic weight of the radiator A periodic curve was obtained in many portions of which the slope was so great that atomic weights might be obtained by interpolation with considerable accuracy

Using a thin plate of aluminium as the absorber, the relation between the absorbability of the radiation and the atomic weight of the radiator was found to be approximately a linear one for a long range of atomic weights on both sides of nickel Nickel itself, however, can only be brought into line by assigning it an atomic weight a little above 61 Many absorbing substances have been used and all give approximately the same value the maximum variation in the values found from these different experiments being about 0 3

The experiments on fairly good commercial specimens indicated an atomic weight of about 61 4 To make the evidence more conclusive and the numerical values as accurate as possible—though a 2 per cent or 3 per cent impurity could not materially affect the result—the purest specimens were used, and the atomic weight found by two separate series of observations did not differ by more than about 0 1 from the value previously obtained We are thus forced to the conclusion that the atomic weight of nickel is about 61 3 Details of these experiments we hope to publish shortly CHARLES G BARKLA

ON HOMER LANE'S PROBLEM OF A SPHERICAL GASEOUS NEBULA

§ 1 A HIGHLY interesting problem of pure mathematics was brought before the world in the *American Journal of Science*, July, 1870, by the late Mr Homer Lane, who, as we are told by Mr T J J See,[1] was for many years connected with the U S Coast and Geodetic Survey at Washington Lane's problem is the convective equilibrium, of density, of pressure, and of temperature, in a rotationless spherical mass of gaseous fluid,[2] hot in its central parts, and left to itself in waveless quiescent ether

§ 2 For the full discussion of this problem we must, according to the evolutionary philosophy of the physics of dead matter, try to solve it for all past and future time But we may first, after the manner of Fourier, consider the gaseous globe as being at any time given with any arbitrarily assumed distribution of temperature, subject only to the condition that it is uniform throughout every spherical surface concentric with the boundary And our subject might be the absolutely determinate problem of finding the density and pressure at every point necessary for dynamical equilibrium But for stability of this equilibrium, Homer Lane assumed, rightly as I believe is now generally admitted, that it must be of the kind which two years later[3] I called convective equilibrium

§ 3 If the fluid globe were given with any arbitrary distribution of temperature, for example uniform temperature throughout, the cooling, and consequent augmentation of density of the fluid at its boundary, by radiation into space, would immediately give rise to an instability according to which some parts of the outermost portions of the globe would sink, and upward currents would consequently be developed in other portions In any real fluid, whether gaseous or liquid, or liquid with an atmosphere of vapour around it this kind of automatic stirring would tend to go on until a condition of approximate equilibrium is reached, in which any portion of the fluid descending or ascending would by the thermodynamic action involved in change of pressure, always take the temperature corresponding to its level, that is to say, its distance from the centre of the globe

§ 4 The condition thus reached, when heat is continually being radiated away from the spherical boundary is not perfect equilibrium It is only an approximation to equilibrium, in which the temperature and density are each approximately uniform at any one distance from the centre and vary slowly with time, the variable irregular convective currents being insufficient to cause any considerable deviation of the surfaces of equal density and temperature from sphericity

§ 5 A very interesting and important theorem was given by Prof Perry on p 252 of NATURE for July, 1899 according to which, for cosmical purposes, it is convenient to divide gases into two species—species P gases for which the ratio (k) of thermal capacity, pressure constant to thermal capacity volume con-

[1] 'Researches on the Physical Constitution of the Heavenly Bodies" *Astr Nachr*, November, 1905)

[2] By a gaseous fluid I here mean what is commonly called a "perfect gas" that is a gas which fulfils two laws —(1) Boyle's law At constant temperature it exerts pressure exactly in proportion to its density, or in inverse proportion to the volume of a given homogeneous mass of it. (2) A given mass of it kept at constant pressure has its volume exactly proportional to its temperature, according to the absolute thermodynamic definition of temperature (Preston's "Theory of Heat," Article 290) According to the "Kinetic Theory of Gases, every gas or vapour approximates more and more closely to the fulfilment of these two laws, the smaller is the proportion of the sum of times in collision to the sum of times of moving approximately in straight lines between collisions

[3] 'On the Convective Equilibrium of Temperature in the Atmosphere" (Literary and Philosophical Society of Manchester, January 21, 1862, re published as Appendix E, Math and Phys Papers, vol iii)

stant, is greater than $1\frac{1}{4}$, species Q, gases for which k is less than $1\frac{1}{4}$. On looking at the page of NATURE referred to, it will be seen that Perry questioned or even denied the possibility of a gas of species Q. His theorem is:—*A finite spherical globe of gas, given in equilibrium with any arbitrary distribution of temperature having isothermal surfaces spherical, has less heat if the gas is of species P, and more heat if of species Q, than the thermal equivalent of the work which would be done by the mutual gravitational attraction between all its parts, in ideal shrinkage from an infinitely rare distribution of the whole mass to the given condition of density.*

§ 6. From this we see that if a globe of gas Q is given in a state of convective equilibrium, with the requisite heat given to it, no matter how, and left to itself in waveless quiescent ether, it would, through gradual loss of heat, immediately cease to be in equilibrium, and would begin to fall inwards towards its centre, until in the central regions it becomes so dense that it ceases to obey Boyle's law, that is to say, ceases to be a gas. Then, notwithstanding Perry's theorem, it can come to approximate convective equilibrium as a cooling liquid globe surrounded by an atmosphere of its own vapour.

§ 7. But if, after being given as in § 6, heat be properly and sufficiently supplied to the globe of Q-gas at its boundary, and the interior be kept stirred by artificial stirrers, the whole gaseous mass can be brought into the condition of convective equilibrium.

§ 8. In the course of the communication to the Royal Society of Edinburgh, curves were shown representing the distributions of density and temperature in convective equilibrium for four different gases, corresponding to the four values of k:—

Gas (1) $k=1\frac{2}{3}$ (approximately the value of k for the monatomic gases, mercury vapour according to Kundt and Warburg, argon, helium, neon, krypton, and xenon).

Gas (2) $k=1\frac{2}{5}$ (approximately the value of k for seven known diatomic gases, hydrogen, nitrogen, oxygen, carbon monoxide, nitric oxide, hydrochloric acid, hydrogen bromide).

Gas (3) $k=1\frac{1}{3}$ (approximately the value of k for water vapour, chlorine, marsh gas, bromine iodide, chlorine iodide).

Gas (4) $k=1\frac{1}{4}$ (approximately the value of k for sulphur dioxide).

Four of these curves agree practically with curves given by Homer Lane for $k=1\frac{2}{3}$ and $k=1\frac{2}{5}$, in his original paper to the *American Journal of Science*, July, 1870.

§ 9. In a communication to the Edinburgh Royal Society of February, 1887, "On the Equilibrium of a Gas under its own Gravitation only," I indicated a graphical treatment of Lane's problem by successive quadratures, which facilitated the accurate calculation of numerical results, and was worked out fully for the case $k=1\frac{2}{5}$ by Mr. Magnus Maclean, with results shown in a table on p. 117 of the Proceedings of the Royal Society of Edinburgh, vol. xiv., and on p. 292 of the *Phil. Mag.*, March, 1887. The numbers in that table expressing temperature and density are represented by two of the curves now laid before the society. The other curves represent numerical results calculated by Mr. George Green, according to a greatly improved process which he has found, giving the result by step by step calculation without the aid of graphical constructions.

The mathematical interpretation of the solution for Perry's critical case of $k=1\frac{1}{5}$, and for gases of the Q-species, is exceedingly interesting.

The communication included also fully worked out examples of the general solution of Lane's problem for gases of class P of different total quantities and of different specific densities.

§ 10. In my communication to the Royal Society of Edinburgh, of February, 1887, I pointed out that Homer Lane's problem gives no approximation to the present condition of the sun, because of his great average density (1.4). This was emphasised by Prof. Perry in the seventh paragraph, headed "Gaseous Stars," of his letter to Sir Norman Lockyer on "The Life of a Star" (NATURE, July 13, 1899), which contains the following sentence:—

"It seems to me that speculation on this basis of perfectly gaseous stuff ought to cease when the density of the gas at the centre of the star approaches 0.1 or one-tenth of the density of ordinary water in the laboratory."

KELVIN.

THE PROBLEM OF THE RHODESIAN RUINS.[1]

THE recent investigation of some of the famous ruins of Rhodesia, conducted in 1905 by Dr. D. Randall-MacIver on behalf of the British Association and the Rhodes trustees, has resulted in an entirely fresh view of their origin and age. The hitherto generally accepted view, that these buildings were erected in very ancient days by a Semitic people, whose search for gold led them thus far afield, has received a serious check. Dr. MacIver's researches, conducted upon the lines of archæological investigation, point to the buildings in question being of comparatively recent date, not earlier, in fact, than late mediæval times. This result is the more striking when we remember that his previous researches have been mainly archæological, conducted chiefly in Egypt, and that, in consequence, we might expect a certain degree of bias in favour of retaining the ruins within the sphere of archæology. That a trained archæologist has been unable to find evidence of high antiquity upon the sites investigated is at least a strong point in favour of his argument.

Dr. MacIver made excavations on seven sites in various parts of Rhodesia, these being:—(1) Inyanga, on the Cecil Rhodes estate, sixty miles north of Umtali, (2) the Niekerk ruins to the north-west of Inyanga, (3) a site three miles south of Umtali; (4) Dhlo Dhlo, in the Incisa district, (5) Nanatali, sixteen miles east of Dhlo Dhlo, (6) Kami, fourteen miles west of Bulawayo, and (7) Great Zimbabwe, in the Victoria district, the site which hitherto had received the greatest attention. These sites were well selected as being distributed over a wide area, and, moreover, as differing considerably from one another both in general character and in special features, as also in the greater or less degree of elaborateness in their structure. It may be remarked at once that the distinctive features observable in comparing the different buildings are often no less remarkable than are the points of similarity. No two seem to be alike, and the divergences and specialisation render their individuality very striking.

The principal questions to be determined in regard to these remarkable buildings were: By what people and at what period were they erected? The controversy, which is still active, centres mainly upon these two main points, and the older theory of their Semitic origin and great antiquity, urged by Mauch, Bent, Keane, Hall, and others, is being maintained steadfastly and strenuously by several authorities. Dr. MacIver in the title of his book, "Mediæval Rhodesia," has hoisted his fighting flag. His conten-

[1] "Mediæval Rhodesia." By Dr. David Randall-MacIver. Pp. xv+106. (London: Macmillan and Co., Ltd., 1906.) Price 20s. net.

tion is that none of these buildings are referable to an earlier period than mediæval or post-mediæval times. He argues that none of the objects hitherto discovered in excavating within the area of the ruins would be recognised by an archæologist as "more than a few centuries old, and that the objects when not immediately recognisable as mediæval imports, are of characteristically African type." Inyanga and the Niekerk ruins do not appear to have produced any but native African objects, and at Umtali a fragment of glazed stoneware was the only foreign object found. At the better-known sites, Dhlo Dhlo, Kami, Nanatali, and Zimbabwe, a fair number of imported objects have been found; but here again Dr MacIver holds that in no case is there evidence of a pre-mediæval antiquity. As far as possible, he endeavoured in his excavations to reach the lowest strata, and to explore the levels which must be contemporary with the earliest portions of the walls of the buildings, and the objects found therein were naturally considered by him of the highest importance.

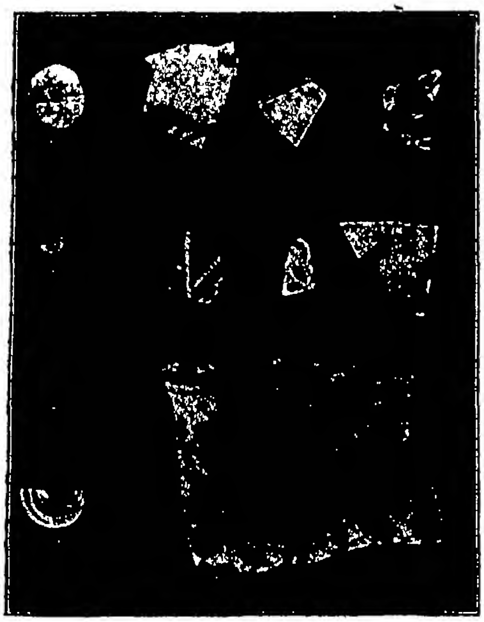

FIG. 1.—China and Ivory and Shell Beads found at Dhlo Dhlo. From "Mediæval Rhodesia."

It was at Dhlo Dhlo that he discovered his most valuable piece of evidence. The absence of objects of foreign workmanship and of known date at the Inyanga, Niekerk, and Umtali sites rendered impossible the assignment of any definite period to the buildings there, although the negative evidence may be held to indicate the lack of foreign influence, which itself may possibly be regarded as pointing to these sites being earlier than the others which were examined, a view which is held by the author on structural grounds. At Dhlo Dhlo, on the other hand, numerous imported objects were found, and in excavating one of the platforms upon which a dwelling had been erected, and which Dr MacIver asserts most positively is contemporaneous with the earliest portion of the building, he came across a piece of blue and white Nankin china in the unbroken cement floor of the dwelling. This fragment is shown (No. 20) in the illustration reproduced. If this cement floor was, as he maintains, erected at the same time as the oldest walls of the main building, we must certainly admit the validity of his contention that the building cannot antedate the fragment of porcelain, and that the date of erection, therefore, cannot be pushed back beyond late mediæval times. His critics appear willing to admit the validity of his argument as regards Dhlo Dhlo, but they urge that the buildings on this site are relatively late, and that this dating will not hold good in the case of the buildings at Great Zimbabwe, which they regard as much earlier.

Dr MacIver regards the principal buildings, such as the so-called "Elliptical Temple" at Zimbabwe, as being fortress-kraals, and urges that the "Elliptical Temple" itself was the fortified residence of the Great Chief, or Monomotapa, whose sway extended over an enormous area and a very extensive population. To understand how architectural feats, such as the finer Rhodesian buildings at Dhlo Dhlo, Nanatali and Zimbabwe, can have been achieved by the precursors of the modern South African natives, it is necessary to assume that in those days there was organisation of a far higher character than has obtained in recent years, organisation under great chiefs whose power and intelligence were of a relatively high order. This would appear, from the Portuguese and other records, to have been the case in the days of the Monomotapan empire of the Middle Ages down to the close of the sixteenth century. The Monomotapa, or paramount chief, may well have resided at Zimbabwe, and he is recorded to have had captains in various fortresses elsewhere. The organisation of labour implied by the elaborate and decorated stone architecture is certainly remarkable, more particularly when we compare these edifices with the results of the constructional efforts of the modern Kafir peoples, but under an intelligent and powerful ruler, and under stable conditions of life, a degree of culture may have been reached far higher than it is possible for smaller communities under lesser chiefs to maintain. It seems well within the bounds of probability that under such conditions even the finer buildings may have been erected by the more progressive and united precursors of the present native inhabitants of Rhodesia.

Even more remarkable in some respects, than the huge "fortified kraals" are the terrace walls on the Niekerk site described by Dr MacIver. These stone-built walls form irregular concentric rings round the hills upon which the villages were situated, and although structurally simple, cover an enormous area extending in close formation over a space of upwards of fifty square miles. They do not appear to have been erected as supporting walls for agricultural terraces nor to have been connected with an irrigation system, and, in the absence of evidence to the contrary, one must assume that their purpose was defence, though one accepts this view somewhat reluctantly, for, when regarded as an elaborate system of defensive girdle walls, one cannot but admit that their practical value is hardly commensurate with the enormous labour expended upon them. They recall to one's mind the *sementera* walls of Luzon, in the Philippines, which also form long, irregular, though concentric alignments up the slopes of the hills, following their contours, covering, too, a very large extent of country. In the case of the *sementeras* there are transverse walls dividing up the terraces into sections. They are purely for agricultural purposes, and are mostly, though not all, connected with a wonderful system of irrigation. It might be of use to compare the *sementera* system with the Niekerk terrace walls, on the chance of a clue to the

latter being found, and it is to be hoped that an accurate survey may eventually be made. The scientific study of the ruins is still in its infancy, and a vast amount of work remains to be done. As has been said, there are two distinct and antagonistic theories of their origin. It is eminently to be desired that the Rhodesian authorities will in every way encourage, nay, promote, further detailed excavations by trained men of science. Such a work would redound greatly to the credit of Rhodesia, and would be followed with the greatest interest throughout the scientific world. It would imply the exploitation of

It has been urged that the ruins have been shorn by Dr. MacIver of their romance. Taking the term romance in its strict sense, this may be true. For legendary uncertainty he has sought to substitute scientific fact. For ill-defined Semitic invaders he offers a native indigenous people, and King Solomon and the Queen of Sheba he replaces with the Monomotapa. How far he is justified will be shown by future investigations. At least he has presented his case in a straightforward and lucid manner in a very attractive and well-illustrated book, and it does not appear that the problem is in any way less fascinating

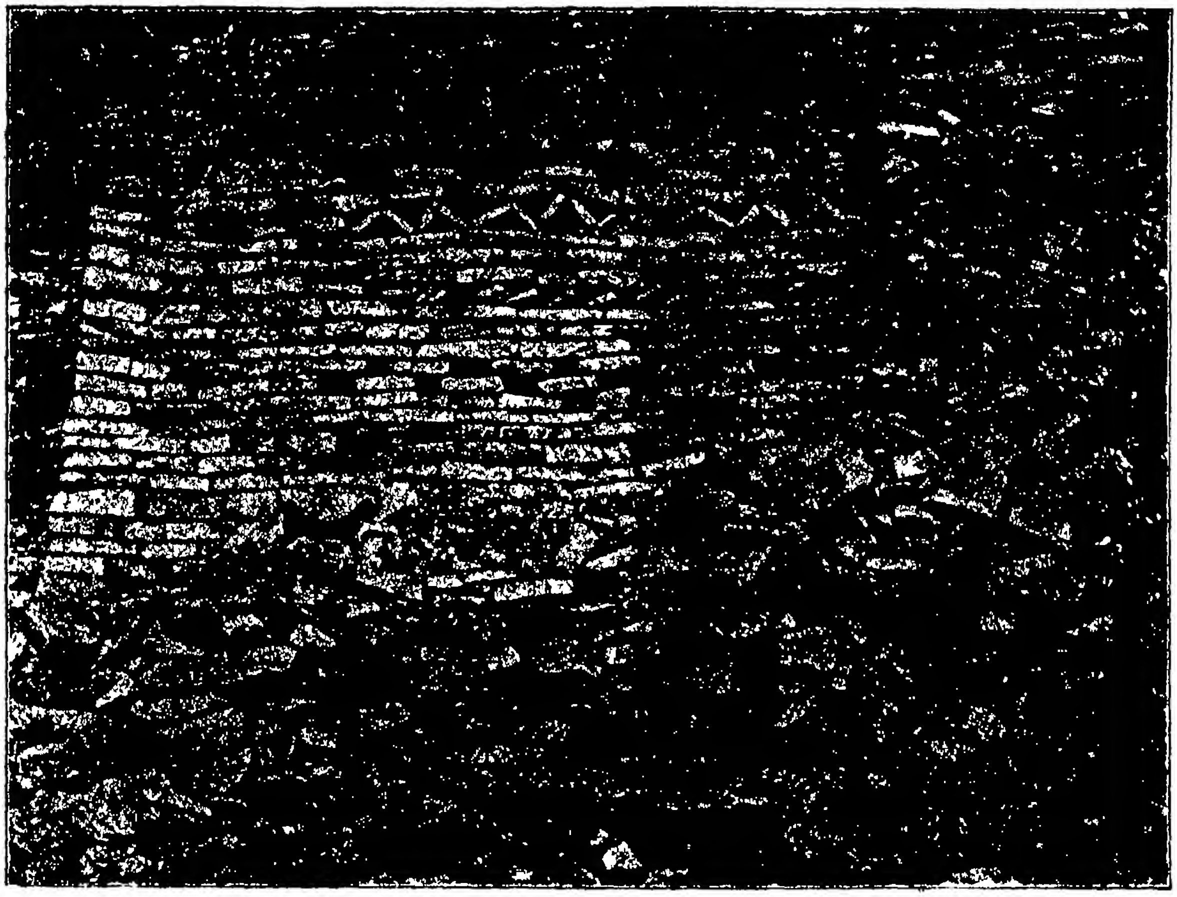

FIG. 2.—Decoration of West Side of Main Entrance, Dhlo Dhlo. From "Mediaeval Rhodesia."

one of the most valuable scientific assets of the country. Dr. MacIver makes out a strong case, but it is desirable to know more precisely to what group of Bantu peoples the buildings are assignable. Whence came they? Many of the native objects found are identical with those in use by the modern Kafir peoples, others, on the other hand, show affinities with a north-western culture and appear almost out of place where found. Then again, the older gold mines themselves have hardly been examined at all in detail. They should yield material of importance. It is further desirable to explain more fully the individuality of the different settlements and of the arts of their former inhabitants; to diagnose, for instance, the presence of very numerous stone carvings at the Umtali ruin, excavated by Captain E. M. Andrews, in the light of their prevailing absence elsewhere.

or less worthy of accurate study for having, perhaps, been transferred from the province of archæology to that of ethnology.

PROF. D. I. MENDELÉEFF.

DEATH has been very busy of late among the army of men of science, and nowhere has he been more active than in Russia, where within the space of a few weeks three of that country's foremost chemical philosophers—Beilstein, Mendeléeff, and Menschutkin—all men of front rank and of a world-wide reputation, have submitted themselves to the strict arrest of the fell sergeant. An occurrence of like character and extent is almost unknown in the annals of science. The nearest approach to it is in our own history, when within an interval hardly greater we lost Wollaston, Young, and Davy.

To Beilstein's life and services to chemical science we have already made reference, of Menschutkin, whose death has only just been announced, we hope to speak later. Our immediate concern is with the most distinguished of the eminent triumvirate—Dmitri Ivanovitsch Mendeléeff. The chief facts of Mendeléeff's personal history have been given in No. xxvi. of the series of "Scientific Worthies," which appeared in these columns so far back as 1889. It is sufficient here to recall that he was a Siberian, born at Tobolsk on February 7th (N.S.), 1834. He died, therefore, within a week of his seventy-third birthday. He was the seventeenth and youngest child of Ivan Paolowitsh Mendeléeff, Director of the Gymnasium at Tobolsk, who, shortly after the birth of his son Dmitri, became blind and lost his position. The family thereby became practically dependent upon the mother, Maria Dmitrievna Mendeleeva, a woman of great energy and force of character, who established a glass works in the town, on the profits of which she brought up and educated her large family. The story of Mendeléeff's youth and early struggles is given in the preface to his great work "On Solutions," which he dedicated to his mother's memory in a passage of singular beauty and power. At the age of sixteen he was sent to St. Petersburg, but, owing to official restrictions, he was prevented from studying chemistry under Zinin at the University, as he had intended, and was transferred to the Pedagogical Institute, where he came under the influence of Woskresenky in chemistry, and of Lenz in physics. Whilst at the institute he wrote his first paper on "Isomorphism," and after serving in the Gymnasium at Simferopol and at Odessa, he gained his *Magister Chemiae* in 1856, and was made a *privat-docent* in the University of St. Petersburg.

At about this period he was attracted to the special line of inquiry and of speculation which was the dominant and most striking feature of his scientific activity, and which eventually culminated in the great generalisation with which his name is inseparably connected. It is easy to detect in these early attempts at tracing the relations between the physical and chemical properties of substances and their molecular and atomic weights the germs of the conception which eventually took shape as the Periodic Law. His work on specific volumes was begun in 1855, and was continued by him in Heidelberg, where he went in 1859, and where he remained until 1861. Germany would appear to have exercised no permanent influence on Mendeleeff. He worked alone and seems to have derived nothing from personal contact with Bunsen and Kopp. It is significant of his perspicacity that he should at this time have clearly appreciated and publicly declared his belief in the value of Gerhardt's work on the determination of the chemical molecule—at the very period, in fact, when the whole weight of German authority was directed against the doctrine of the new French school. Returning to St. Petersburg, he became professor of chemistry at the Technological Institute. In 1866 he was transferred to the University, and in 1890 he was appointed head of the Standards Department.

Mendeléeff signalised his connection with the University by the publication of his "Principles of Chemistry," which has passed through many editions in Russia, and has been translated into German and English. It is not easy to avoid speaking of this work in terms which savour of hyperbole. Most treatises on chemistry owe a great deal to their predecessors. Indeed there is probably no form of literature which so obviously proceeds on strictly evolutionary principles. But Mendeléeff's great work is a thing apart—something *sui generis*. The bare facts of chemistry, in greater or less detail, are common to all such works, but most of them, we fear, would be classed by Lamb among the books which are no books. It is not so with Mendeléeff's "Principles." In its insight, in its grasp of detail and of principle, in its extraordinary power of coordination, in its suggestiveness, and in its wealth of speculation, it is a book among books, and may be read with profit and a pleasure occasionally tinctured with amusement by every true student, no matter how old. To those who had the good fortune to know its author personally it reflects the man in every page. Even the footnotes are instinct with character and originality. Mendeléeff's "Principles" may be said to stand in the same relation to the chemistry of the latter half of the nineteenth century that Dalton's "New System" did to the chemistry of the earlier half. Each work was the definite and orderly presentation of the doctrine and philosophy of its author.

There is hardly a department of chemistry in which Mendeléeff did not labour, at one time or other, during the thirty years of his activity as a teacher. Chemical mineralogy, chemical geology, and the chemistry of aliphatic substances in turn, and apparently with equal zeal, attracted his attention. It is to this catholicity and power of taking broad and comprehensive views of the operations of chemistry that Mendeléeff owes his eminence as a chemical philosopher. But it is in the domain of physical chemistry that his fame as a worker chiefly rests. His early papers on the thermal expansions of liquids above their boiling points up to temperatures at which their cohesion and latent heats are *nil*, and at which the liquid becomes gaseous independently of pressure and volume, anticipated the researches of Andrews, and were, in their turn, a development of the observations of Cagniard de la Tour, Wolff and Drion.

The same faculty of perceiving the underlying basis of a physical generalisation is seen in the notable paper which he communicated to our Chemical Society in the year following his election into that body as an honorary foreign member, in which he developed a general expression for the expansion of liquids under constant pressure, analogous to that which expresses Dalton's law of the uniformity of expansion of gases. The formula $V = 1 + kt$ applies only to a so-called ideal gas; in like manner, Mendeléeff's expression is to be regarded only as a first approximation—that is, as applicable only to ideal liquids. In the case of actual liquids the deviations from the ideal form increase not only as the liquid approaches the point of change of state of aggregation, but also augment with diminishing density, increasing cohesion, and diminishing molecular weight, just as Mendeléeff himself showed that the deviations from Dalton's law were related to the molecular weights of the gases. Subsequent observers by applying van der Waals's theory of the relation between pressure, volume, and temperature, have shown that the development of Mendeléeff's formula affords a simple and ready method of calculating the critical temperature of bodies from their thermal expansions as liquids—in other words, of reaching the same constant by a method analogous to that employed by Mendeléeff himself to the observations of Kopp and Pierre.

Mendeléeff's work on the relative densities of aqueous solutions of alcohol takes its place as a classic alongside the works of Blagden and Gilpin, and of Drinkwater and Fownes in this country, and, as in the case of these observations, has been utilised by Continental Governments for the purposes of revenue. These determinations were applied by Mendeléeff to the elucidation of a theory of solution, and in a paper, also communicated to our Chemical Society, he sought by means of them to reconcile Dalton's doctrine of the atomic constitution of matter with modern views re-

speeding dissociation and the dynamical equilibrium of molecules. How far this attempt will be ultimately successful time alone can show. Mendeléeff had little sympathy with the theory of electrolytic dissociation, which, he declared, was not in harmony with the facts of observation, and was of little use in facilitating our comprehension of the true nature of solution. Nor was he more predisposed towards the conception of electrons, although perhaps his belief in the integrity of the atom was hardly so fundamental as that of Dalton, who would have gone to the stake rather than recant his declaration: "Thou canst not split an atom!"

The story of the rise and development of the Periodic Law is so well known that it is unnecessary now to dwell upon it. By a good fortune, which some may regard as evidence of predestination, Mendeleeff lived to see the verification of his predictions in the discovery, in rapid succession, of gallium, scandium, and germanium, and no seer ever prophesied more truthfully. It was the astonishing accuracy of Mendeléeff's prognostications, and the apparent boldness and confidence with which they had been uttered, that profoundly impressed the whole scientific world, and secured for his generalisation a respect and acceptance for which otherwise it would have had long to wait. This generalisation is now woven into the fabric of modern chemistry, and is universally accepted as the only rational basis of classification. Like many other great natural truths, we are able, on looking back, to discern its germs in the tentative efforts of previous thinkers who more or less dimly appreciated the significance of the facts upon which it is based, but it is perfectly certain that Mendeléeff knew nothing of the prior work of De Chancourtois and of Newlands, and was no more influenced by it than was Dalton by Richter or by the "Comparative View of the Phlogistic and Antiphlogistic Theories" of William Higgins. In the memorable Faraday lecture which he gave to the Chemical Society in 1889, Mendeléeff, with a true nobility of mind and a modesty which revealed the real greatness of the man, gave adequate expression to his appreciation of the efforts of his predecessors, claiming for himself only courage and intrepidity in placing "the whole question at such a height that its reflection on the facts could be clearly seen."

The Periodic Law has so far stood the test of experience, and each new extension of the science is consistent with its previsions. The inert gases of the atmosphere find their place in the system, and the only radioactive substance the chemical properties of which have been sufficiently investigated has an appropriate position among its correlated elements. In the old days the followers of Stahl sought to make the conception of phlogiston an all-embracing doctrine. Mendeléeff anticipated these attempts as regards his own generalisation by showing that even the universal ether may be included within his system. In his last paper, published in 1902, entitled "An Attempt towards a Chemical Conception of the Ether," he starts with the assumption that the ether possesses mass, and that it has an atomic weight many times less than that of hydrogen, something of the order of 10^{-6} when $H=1$, that it is monatomic like argon and helium, and that by its small density and extremely rapid motion it permeates all matter and space. The ether thus becomes, not an affection of matter, but a distinct entity capable of being attracted by elements in proportion to the weights of their atoms, and he held that the phenomena of radio-activity could be explained by the gradual emission of this ether from such substances as uranium and thorium which have the highest atomic weights of the elements.

The truth embodied in the Periodic Law has led many to suppose that this generalisation lends support to, and is indeed the proof of, the validity of the assumption of a primordial matter. Mendeléeff himself declined to see that such an inference was warranted. He saw nothing in the law inconsistent with the idea of the individuality of the elements, holding that until it could be definitely shown that one element could be transformed into another, or that ether and matter were mutually convertible, the elements must be regarded as distinct and separate entities, immutable and unchangeable.

Mendeléeff not unfrequently visited this country, and was personally known to many British chemists, to whom he was always welcome. His tall and commanding presence, his fine head, with its tangle of long, wispy white hair, his expressive features, his guttural utterance, the wisdom and originality of his talk, his shrewdness and sense of fun, all stamped him as an uncommon and strong personality, which immediately made its presence felt in any company in spite of the innate modesty of the man. Of wide liberal views, intensely national, and a great power in the University, Mendeléeff was doubtless a thorn in the side of bureaucratic Russia, and it was currently reported that the frequent foreign missions on which he was sent were so many covert attempts to keep him at arm's-length.

Every scientific honour that this country could pay was awarded to him, and he was profoundly touched and deeply grateful for the sympathy and appreciation thus extended to him. On the occasion of his delivering the Faraday lecture it fell to the writer's duty, as treasurer of the Chemical Society, to hand him the honorarium which the regulations of the society prescribe, in a small silken purse worked in the Russian national colours. He was pleased with the purse, especially when he learned that it was the handiwork of a lady among his audience, and declared that he would ever afterwards use it, but he tumbled the sovereigns out on the table, declaring that nothing would induce him to accept money from a society which had paid him the high compliment of inviting him to do honour to the memory of Faraday in a place made sacred by his labours.

T. E. THORPE.

PROF. ANTONINO MASCARI.

BY the death of Prof. Antonino Mascari on October 18, 1906, solar physicists throughout the world, and more particularly those who were his intimates in the Italian observatories, have sustained a severe loss.

Born at Campobello di Mazzara (Sicily) on December 4, 1862, Mascari proceeded in due course to the University of Palermo, where he took the engineering course and obtained his degree in that faculty in 1887. It was while there that he developed the predilection for astronomical investigations, and, under the guidance of Prof. Riccò, worked with that activity and intelligent ability which were the outstanding features of his whole career. He was later appointed to the position of assistant to the Piazzi Foundation, and thus was fortunate enough to be able to continue his association with Prof. Riccò—an association which has proved of inestimable benefit to the study of solar physics.

In 1892 Mascari was appointed first assistant at the Observatory of Catania, where the solar prominence observations, commenced by Tacchini at Palermo in 1872, were continued. Probably only those who have had to use these Italian observations in discussions of collateral phenomena are aware how well this task was performed, and how much the science of solar physics owes to the indefatigable labours

and lucid exposition of Prof. Riccò's worthy successor. This work was continued right up to the commencement of his last illness, and we find that the discussion of the observations for the first semester of 1906 was carried out, and published in the *Memorie*, by Mascari.

Although his chief work lay in the province of solar physics, Mascari will also be remembered as a careful observer in other departments of astronomical physics. At the Catania and Etna observatories he made careful telescopic studies of various planets, Saturn and Venus among others. During the latter part of 1892 he noted several well-marked features on Venus, and, from their persistence in the same relative positions on the disc, he inferred that the short period rotation of the planet was out of the question, thus confirming Schiaparelli's conclusion that the period of rotation is equal to that of the planet's revolution in its orbit. Tacchini's observations of about the same date also confirmed this fact.

Mascari was also an authority on the subject of the agitation of telescopic images, more especially that of the sun due to movements in the earth's atmosphere. In collaboration with Signor A. Cavasino he published an exhaustive memoir on this subject in 1905, discussing the observations of the solar image which were carried out at Palermo and Catania during the twenty-three years 1881–1903.

With Prof. Riccò, Mascari was instrumental in carrying on the work in connection with the Catania zone of the Astrographic Chart and Catalogue, the taking and reduction of a large number of the requisite photographs being due to his personal labours. In 1904 he was nominated adjoint-astronomer at Catania, and took a prominent part in the admirable organisation and direction of the observatory work. But it was in the study of solar physics that Mascari's life-work lay, and it is in solar physics that his loss and the true value of his works will be most keenly recognised. This feeling is ably expressed in an obituary notice by Prof. Riccò, published in the *Astronomische Nachrichten*, to which we are indebted for some of the foregoing particulars.

W. F. ROLSTON.

NOTES

THE death on Tuesday of Prof. H. F. Pelham, president of Trinity College, Oxford, and Camden professor of ancient history in the University, at sixty-one years of age, means a great loss to national scholarship and active study. Prof. Pelham took a keen interest in scientific progress, and while a member of the Hebdomadal Council at Oxford he was always on the side of learning and research. Women's education in Oxford had in him a powerful champion, and Somerville College in particular owed a great debt to him for his enthusiastic service on its council. He did much for the promotion and management of the British School at Athens and the British School at Rome, his zeal on behalf of these institutions being based on the conviction of the value of Greek and Roman life and literature as a subject of scientific study. Prof. Pelham was one of the first members of the British Academy.

IN the course of a letter in Wednesday's *Times*, Prof. E. B. Poulton refers to the efforts which have to be made in this country to induce the official representatives of the nation to assist the advancement of science in any particular direction. Instead of seeking the best expert advice upon any subject in which science can be of service, the Government waits to be memorialised before it can be stimulated into action. "The disheartening distance," Prof. Poulton adds, "which, in this respect, separates us from Germany was forcibly brought to my mind at the meeting of the International Zoological Congress in 1901. The fact that the German Empire is penetrated by a belief in the importance and the dignity of science was impressed upon us by the splendid reception in Berlin, by our meetings in the building of the Reichstag, and by every kind of Governmental and municipal recognition and hospitality. In this country unfortunately the conviction that science is of national importance is almost confined to that small part of the nation which includes the scientific men themselves. They know that the existence of the Empire depends upon science, and that, if disaster should overwhelm the island centre, it will be for want of science. Scientific men can fairly claim that there is love of their country no less than love of their subject in the attempts to conquer indifference and even dislike in those who bear the responsibility and wield the power."

AN aurora was observed in most parts of the United Kingdom last Saturday evening, February 9, and in many widely separated places the display is described as being brilliant. The time of occurrence was chiefly between 6 p.m. and 11 p.m., and it was accompanied by a considerable magnetic disturbance, particulars of which are given by Dr. Chree in our correspondence columns. It is noteworthy that sun-spots have been unusually prominent recently, and that at the present time no fewer than four distinct groups are visible, one of which can be seen with the naked eye. London and, indeed, nearly the whole of the south-east of England was enveloped in a thick fog on Saturday evening, which effectually prevented all possibility of the aurora being seen in this part of the kingdom, but it was seen at Oxford. Reports are numerous from the north and west of England as well as from Scotland and Ireland. Many observers give the colouring as yellow, green, rose red or purple, and allude to the flickering or quivering rays. Writing from Winchmore Hill, Amersham (Bucks), Mr. A. M. Davies says that between 10.30 p.m. and 11 p.m. he noticed that the sky was deep pink or crimson in the N.E. and pale green in the N.W. At intervals beams of light were seen at various points, all radiating from some way below the northern horizon. Sometimes there was also a flickering effect, as though horizontal bands of light and shade rose up in quick succession. Dr. W. N. Shaw, director of the Meteorological Office, has kindly sent us a letter received by him from Mr. G. A. Clarke, the observer at the Aberdeen University Observatory. The following extract from this letter describes the chief characteristics of the display:—"The first faint streamers were seen by me a few minutes before 6 p.m., directed from N.N.W. towards the zenith. About thirty minutes later these had increased in brilliancy, while an extended diffuse greenish glow was visible in the N.E., and a faint white band crossed the zenith from E.N.E. to W.S.W. This band rapidly increased in brightness and size until it finally became a bright greenish-white zone girdling the sky from E.N.E. to W.S.W. horizons, and between 50° and 60° south of the zenith. It passed right through the 'belt' of Orion. At 6.45 p.m. a patch of deep red appeared in the north, accompanied by some very bright greenish-yellow streamers. The streamers increased in quantity, and worked upwards toward the zenith, while the band above-mentioned remained steadily in its position until after 9 p.m. Two other faint bands formed near the zenith, but they were merely transitory. Between 7 p.m.

and 8 p.m. some more red and rosy glows were seen in the N.W., but the prevailing colour was greenish-white. At frequent intervals after 8 p.m. the sky at the zenith was occupied by very rapidly moving wavy bands of pale white, which, though rather confused in direction, yet seemed to possess a distinctly undulatory motion towards the S. The streamers continued to shoot upwards with varying brightness, the points of maximum brilliance being in the N.W. and N.E., and occasionally a slight corona was formed overhead. Probably the most noteworthy feature of the display was the fact that it continued from about 6 p.m. until after midnight."

WE record with regret the death of Lord Goschen on February 7 at seventy-six years of age. The deceased statesman's reputation was chiefly gained in the world of politics, though he was well known as an author, economist, and educationist. His masterly book on "The Theory of the Foreign Exchanges" still remains the highest authority on the subject. Another volume, "Essays and Addresses on Economic Questions," was published as recently as 1905. Lord Goschen showed a keen interest in educational matters, he was an early promoter of university extension, and took a leading part in the movement for the abolition of tests in the universities. He was elected a Fellow of the Royal Society in 1872. He was twice Lord Rector of the University of Aberdeen, and once of the University of Edinburgh. In 1903 he was elected Chancellor of Oxford University in succession to the late Lord Salisbury, an honour he enjoyed until his death.

THE gold medal of the Royal Astronomical Society was presented on February 8 to Prof. E. W. Brown, F.R.S., for his "Researches in the Lunar Theory." Mr. H. F. Newall, F.R.S., was elected president of the society in succession to Mr. W. H. Maw.

THE *Chemist and Druggist* announces that the Paris Municipal Council has voted a credit of 3800 francs (152*l*.) toward a monument to the late Prof. Curie in the Paris School of Physics and Chemistry.

REUTER'S Agency states that Major Powell Cotton has sent home a complete skeleton of an okapi, the skull of which is said to be probably one of the most remarkable specimens ever brought to this country. In addition, there is a beautifully marked and perfect skin in a better condition than that now in the national collection. Major Powell Cotton has also sent to England the skin of a young okapi. All are now at the British Museum.

THE American Geographical Society has awarded the Cullum medal for the year to Dr. Robert Bell, F.R.S., chief geologist of the Geological Survey of Canada, as a mark of its appreciation of the great value of his extensive surveys and explorations during a long period. This is the first time the medal has been presented to a geographer who is not a citizen of the United States, and this fact gives additional value to the award.

AT a general meeting on January 25 of the Paris Société d'Encouragement pour l'Industrie nationale, the gold medal of economic arts for the year 1906, on which is an effigy of Ampère, was awarded to M. d'Arsonval for his investigations in electricity. The society awards every year on the recommendation of one of the six committees of the council, a gold medal carrying the likeness of some leader distinguished in science or art, to the authors—French or foreign—of works which have exercised the greatest influence on the progress of French industry during the six years preceding the award.

WHEN attention was directed last summer to the threatened danger to the continued efficiency of the Royal Observatory, Greenwich, likely to be caused by the London County Council electrical generating station erected half a mile due north of the observatory (NATURE, June 28, 1906, vol. lxxiv., p. 200), a special committee was appointed by the Admiralty to inquire into the working of the station. The committee, which consisted of Lord Rosse, representing the Royal Observatory, Prof. J. A. Ewing, representing the Admiralty, and Sir Benjamin Baker, representing the Council, has now issued its report, and the conclusions arrived at are contained in the following recommendations:—(*a*) The question, both as regards effects of vibration and obstruction through chimneys or discharge from chimneys, to be further reviewed after, say, two years, by which time experience should be obtained with the second portion of the station at work. (*b*) The generating plant for the second portion to be turbines, which, as well as the dynamos, must be of a perfectly balanced type such as has been proved by trial not to cause vibration. (*c*) An undertaking to be obtained that when the plant in the second portion is available for use the reciprocating engines of the first portion shall not in ordinary circumstances be used after 10 p.m., and their use shall be restricted as far as possible after 8.30 p.m. (*d*) The two chimneys of the second portion, at present incomplete, to be not higher than 204 feet above Ordnance datum. (*e*) The discharge of gases both from these and from the existing chimneys not to be materially hotter than the discharge is now from the existing chimneys—namely, about 250° F. (*f*) No further extension of the station to be made beyond the 20,000 kilowatts now contemplated in the equipment of the second portion.

THE annual dinner of the students' union of the London School of Economics took place on February 9. Mr. Haldane, in proposing the toast of the school, said that idealism is the source of power in religion, in war, in science, in organisation, and the London School of Economics owes its strength and vitality to-day to the fact that it was founded by men who believed in large conceptions and who put them into execution without looking to the consequences. Modern applied economics penetrates into every sphere of public life. The result is that the work of such a school as this is not merely to teach but to train. The Chinese Minister, responding, through his interpreter, to the toast of "The Visitors," said when he came to this country, three years ago, there was only a handful of Chinese students here, but now there are more than ten students in the University of London alone, and more than 100 in the whole of Great Britain. Chinese civilisation, he continued, can boast of the three greatest inventions which have revolutionised the whole world—printing, gunpowder, and the mariner's compass. We have improved those inventions with our Western skill and have gradually built up what may be roughly called modern science. It is now the turn of the Chinese, he remarked, to learn modern science from us, and with their Eastern skill to build up the science of the future. Dr. Nansen, who also responded, said there has been a remarkable *rapprochement* between science and practical life as the centuries have marched on. If we go back some centuries we find science living its life to itself without being in touch with practical life at all, but as time passed on science became

the leading energy of modern society To-day no nation can hope to have any success which has not adapted science to its own life The necessity of adapting scientific methods to practical life has become more and more imperative, and it is in fact, the secret of success of any nation to understand the scientific method of organisation thoroughly

THE October (1906) issue of the Proceedings of the Philadelphia Academy contains the second instalment of a paper by Mr H W Fowler on heterognathous fishes (Astyanax and its allies) One new species is made the type of a new genus, while several previously known forms are referred to new subgenera

THE third and fourth parts (issued together) of the eighty-fifth volume of the *Zeitschrift fur wissenschaftliche Zoologie* appeal solely to specialists, the early stages in the development of the ovum in the hedgehog and the formation of the primitive streak in the yolk of the tern forming the subject of two articles, while the third is devoted to the turbellarian worms of the Bernese Oberland

To the January number of the *Entomologist's Monthly Magazine* Lord Walsingham contributes a further instalment of his account of Algerian Microlepidoptera, mainly based on specimens in his own collection, while in both the January and the February issues the Hon Charles Rothschild describes new British fleas A new lantern-fly (Fulgoridæ) infesting bamboos at Darjiling in such numbers as to be termed "a pest" forms the subject of a note by Mr W L Distant in the earlier of the two numbers

IN No 1505 of the Proceedings of the U S National Museum (vol xxxii, p 1) Mr W M Lyon describes and figures a specimen referred to the typical race of the bonte-quagga (*Equus burchelli*) now nearly, if not completely, extinct It was purchased in 1855 from Messrs Barnum, Bailey, and Hutchinson and is now mounted in the National Museum In some details of colouring it differs from the type-specimen figured by Gray, and in this respect comes nearer to one in the Bristol Museum No 1502 of the same publication is devoted to an account, by Mr Lyon of mammals from Butam Island, Rhio Archipelago while in No 1503 Messrs Eigenmann and Bean discuss a collection of Amazonian fishes.

WE have received a separate copy of a paper by Mr G M Thomson on the marine fish-hatchery and biological station at Portobello, originally published in the Transactions of the New Zealand Institute for 1905 Special attention is, it appears, being directed to the life-history of the more important New Zealand food-fishes many of which have unfortunately, usurped names—such as brill, flounder, sole and lemon sole—properly pertaining to European species Some years ago an attempt was made to introduce the European lobster into New Zealand waters, but without success At the date of writing the author states that arrangements were being made for a fresh consignment of these crustaceans which it was proposed to introduce into situations better suited to their requirements

ACCORDING to Fisheries, Ireland, Sci Invest, 1905, No 8, 1907 (this, by the way, being the unsatisfactory abbreviation given of an exceedingly cumbrous and inconvenient title), the season 1905-6 was a most successful one as regards the hatching of salmon and trout, the total output being 6,827,750 salmon 5?2 000 white trout, and 381,000 brown trout fry, the last estimate being, however, probably far below the actual output As regards salmon fry the output exceeds the previous record season by about one million, this excellent result being, as usual, mainly due to the hatching stations at Lismore and Blackcastle Although no record is given (being probably impossible to obtain) as to the percentage of this fry which attains maturity, it seems likely that something has been done to increase this percentage by the greater attention now paid to the proper planting of the fry Recent observations have shown that both salmon and trout fry require food at an earlier stage (long before the absorption of the yolk-sac) when artificially hatched than when naturally reared, and it appears that hitherto the importance of transferring the alevins into suitable waters so soon as they require adventitious nutriment has not been sufficiently recognised

THE Bulletin of the Johns Hopkins Hospital for January (xviii No 190) contains an interesting article by Mr A W Meyer on some characteristics of the medicine in Shakespeare, with a useful bibliography

THE Sanitary Maritime and Quarantine Council of Egypt has published a volume of scientific reports by the members of its medical staff, and edited by the president, Dr Ruffer It includes several valuable papers on cholera vibrios and the diagnosis of cholera, on agglutinins, hæmolytic and hœmosozic sera, nephritis &c

THE papers in the *Journal of Anatomy and Physiology* for January (xli, part ii) are of a technical nature Among others, Mr D F Derry describes certain predynastic Egyptian tibiæ showing flattening for which it is difficult to account Prof Symmers writes on accessory coronary arteries and Dr T Lewis discusses the interpretation of sphygmographic tracings

A VALUABLE bulletin, compiled by Dr G F White, and entitled "The Bacteria of the Apiary with Special Reference to Bee Diseases" has been received (technical series, No 14, U S Department of Agriculture Bureau of Entomology) It summarises the characters of various bacteria which have been isolated both from normal and from abnormal bees In America, "foul brood" appears to be a disease different from the European one and to be due to a bacillus (*B larvae*) distinct from the *B alvei* of Cheshire and Cheyne

WE have received a reprint of an article by Mr P D. Strachan on undulant (Mediterranean) fever in South Africa, showing that this disease is widely distributed in that part of the world The majority of those who had suffered from the fever used goats' milk, and in several instances the blood and milk of some of the goats agglutinated the *M melitensis* The researches of the Mediterranean Fever Commission have shown that in Malta the goats are frequently infected and transmit the microbe in their milk and Mr Strachan's investigations in South Africa thus help to strengthen the view that the disease is mainly conveyed to man by the milk of infected goats

UNDER the title of "Competition in the Production of Raw Silk Mr S Ito has written a valuable treatise on the economics of the silk industry, published as vol ii, part iv of the Journal of the Agricultural College, Sapporo, Japan Commencing with the early records of cultivation in China and its subsequent extension to other countries, the writer proceeds to contrast the conditions

of the industry in China, Japan, and south European countries Finally, he offers some pertinent remarks as to future production and the directions in which improvements may be effected

As an instance of a superstition connected with the moon's phases, Mr E P Stebbing refers in the *Indian Forester* (November, 1906) to a popular idea among the natives of India that bamboos should not be felled when the moon is full on account of the increased danger of attack by boring beetles While, as usual, the argument is unsound, there would appear to be a germ of truth in the superstition, as experiments, inconclusive, it is true, tend to show that the beetles attack bamboos stacked in the shade in preference to those placed in full light; but with regard to the wider question of felling bamboos, there is more reason for believing that this is best performed during months in the cold season when the beetles do not appear on the wing

THE annual report for 1905–6 of the Agricultural Department, Jamaica, has arrived at a time when the sympathy and assistance of the mother country and many of the colonies is being extended to the inhabitants of that island After suffering from a severe hurricane in 1903, agricultural industries were again expanding and the director of the public gardens and plantations in his report records a large increase in the export of bananas, citrus fruits, cocoa, and coffee Reference is made to trial plots of tobacco at Hope Experiment Station and experiments with cassava, showing that the tubers grown for starch provide a serviceable crop for poor soils Date-palm suckers and Kafir plum plants, *Harpephyllum caffrum* are the latest introductions Dr H H Cousins refers in his report to the investigation of the rum industry as the chief line of chemical work

THE December (1906) number of the Journal of the Royal Horticultural Society contains an account of chrysanthemum cultivation in Japan, by Mr S Hayashi, describing the favourite varieties, the preference of the Japanese for light and artistic flowers is well shown in the types chosen for illustration Even more characteristic are the various effects that are obtained by careful and pre-considered treatment, such as stopping stem and branches in succession until as many as a thousand flowers are produced on a single plant The same writer communicates an account of plants grown in Japan for their edible products in which it is noted that the Japanese cultivate tiger lily bulbs for food, but grow cherry trees mainly for show Mr R H Farrer expresses an English opinion on Japanese flowers and among the list of suggested plants alludes to the beauties of *Rhododendron dilatatum, Lithospermum erythroxylon Schizocodon soldanelloides* and *Iris gracilipes*, but owing to the difference in soil and climate it is doubtful whether these plants can be successfully cultivated in the British Isles

AT the Ceylon Rubber Exhibition it was suggested by Dr J C Willis that, instead of, as at present drying the plantation rubber until it only contains about 0 5 per cent of moisture, it might be advisable to block it in the wet, freshly coagulated condition Experiments with this object were at once carried out by Mr Kelway Bamber the Ceylon Government chemist He prepared the rubber with creosote (to prevent decay and mould) and blocked it at once, getting blocks containing about 9 per cent of water. These sold in London for 5*s* 6*d* per lb against 5*s* 7*d* to 5*s* 9*d* for the ordinary dry Ceylon rubber, thus really getting a much better price A circular (Circular and Agricultural Journal of the Royal Botanic Gardens, Peradeniya, vol iv, No 1) has been lately issued dealing with this matter, and it would seem likely that the old way of making dry biscuits or sheets will soon be extinct

THE Geological Survey of Queensland has issued an interesting report (Publication No 201) on Black Ridge, Clermont, by Mr Lionel C Ball The Black Ridge and the country northwards is at present the mainstay of mining in the district The plateau is covered with basalt, which is underlain by Coal measures and auriferous deposits, the gold occurring in the lowermost portion of the basal conglomerate of the Coal-measures It is believed that the gold was brought in by the same percolating waters that carried the cementing material of the conglomerate, and that it was precipitated by hydrogen sulphide Carbonaceous matter and pyrites do not appear to have been the precipitants In another Publication (No 205) Mr Ball describes the Oaks View gold mines near Rockhampton, and the mines of the Talgai and Thane's Creek goldfields

THE last issue of the *Central* contains a most interesting article, by Mr Maurice Solomon, on carbon making and it is especially valuable from the fact that Mr Solomon is able, from personal knowledge, to describe the processes employed in the only British carbon manufactory which has ever produced carbons of satisfactory quality Mr Solomon gives comparative tables of tests on carbons, and voltage records for the same The comparisons are based on tests made by the National Physical Laboratory

THE *Electrical Review* for February 8 contains a description of the radio telegraph installation for signalling across the Wash which has recently been completed by the Amalgamated Radio-Telegraph Company for the Post Office The plant is installed at Hunstanton in Norfolk and Skegness, in Lincolnshire in both instances at the coastguard stations, being operated by coastguard officers appointed by the Admiralty The installation is primarily for coast communication but will be used by the Post Office for experimental work The mast is of the special design which is as yet confined to the De Forest system, being composed of rectangular baulks of timber bolted together, and is 120 feet in height The aerial consists of six 7/20 tinned copper wires and is so arranged as to be readily lowered or raised Illustrations are given showing the general view of the radio telegraph station and diagrams showing the construction of the mast aerial connections, sending and receiving circuits are also interesting The working of the Wash installation commenced on December 1, 1906 and has been most successful a speed of about thirty five words per minute having been obtained in the electrolytic receiver and telephone circuit

IN the January number of the *Journal de Physique* an interesting article on magnetic detectors and the action of electric oscillations is contributed by M Ch Maurain The author comments on the very complex and apparently contradictory results obtained by the recent experiments of various investigators with magnetic detectors In the first part of his paper M Maurain shows (*a*) that whenever electric oscillations act on magnetism under given conditions the result can be foretold, (*b*) on what the result depends In the second part he deals with magnetic detectors on which it is possible to note the action of electric oscillations with regard to hysteresis in a revolving field He refers for his conclusions to a previous article of his in the *Journal de Physique* (June 17 1906) in which he mentions the works of MM Gerosa Finzi and Mai, and to subsequent experiments made by himself

In an illustrated article on "Recent Progress in Wireless Telephony," by Prof. Fessenden, in the *Scientific American* of January 19, an account appears of a public demonstration given by the National Electric Signalling Company at its Brant Rock and Plymouth stations, which are approximately eleven miles apart. During the demonstration, not only speech, but also phonographic talking records and music were transmitted, and were all successfully received with perfect clearness and distinctness. No extraneous noises of any kind were heard in the receiver, the wireless telephone being so far in advance on the usual wire lines. The National Electric Signalling Company has for some years past been working on various devices to get rid of the extraneous noises which have until lately attended any system of wireless telephony. In the recent demonstration a specially designed dynamo was used in these tests capable of giving 80,000 alternations per second, but the usual number employed is from 50,000 to 60,000. It is claimed that, as developed at present, the system is capable of maintaining communication between ships 100 to 150 miles apart, and wireless telephone messages are now being printed on their reception at the receiving station. A new telephone relay is said to have been invented for use in connection with the above system of wireless telephony and a diagram of connections for this for talking between local exchanges is given, but no details of the relay itself are published. We can only hope that a fuller account of these experiments will shortly appear, and that further improvements will follow which, combined with the recent work of Mr. Poulsen and Prof. Slaby, will make wireless telephony of practical value.

Messrs. Rebman, Ltd., have published a translation, by Mr. H. W. Armit, of the fifth German edition of Prof. August Forel's "Hypnotism or Suggestion and Psychotherapy." The book is described in a subtitle as "A Study of the Psychological, Psycho-physiological and Therapeutic Aspects of Hypnotism," and its price is 7s. 6d. net.

A translation, by Mr. F. Legge, of Dr. Gustave le Bon's "L'Évolution de la Matière" has been published by the Walter Scott Publishing Co., Ltd. The original volume was reviewed at length in our issue of September 21, 1905 (vol. lxxii., No. 1873), and reference may be made to that notice for information as to the subjects dealt with by the author.

Travellers to the East will welcome the new guide-book by Mr. A. G. Plate, which Mr. Edward Stanford has published for the Norddeutscher Lloyd Company of Bremen, under the title "A Cruise through Eastern Seas, being a Traveller's Guide to the Principal Objects of Interest in the Far East." The volume, with its profusion of illustrations and its interesting text, should soon become popular. Its price is 6s.

OUR ASTRONOMICAL COLUMN

The French Eclipse Expedition.—From a message published in No. 5 (1907) of the *Comptes rendus* we learn that the French eclipse expedition under the direction of M. Milan Štefánik was unsuccessful owing to the fact that the sky was covered with clouds during the whole eclipse. It would thus appear that none of the official expeditions dispatched from Europe for this eclipse obtained any photographs, for, as we noted previously, the German and Russian observers were equally unsuccessful.

The Spectroscopic Binary *o* Leonis.—An interesting discussion of the system of *o* Leonis is published in No. 4151 of the *Astronomische Nachrichten* by Herr W. Zurhellen. The discussion is based on observations made with the spectrograph of the Bonn Observatory during April, 1905, and April, 1906. The results obtained from numerous lines of each of twelve plates measured are given separately, and then discussed as a whole. The apparent semi-axis of the relative path of the two components is found to be 0.15884 of the sun's distance, whilst the masses of the components relative to the sun's mass are 1.358 and 1.185 respectively.

Stars with Variable Radial Velocities.—Lick Observatory Bulletin No. 107 contains a number of radial-velocity results obtained at the Lick Observatory and by the D. O. Mills expedition to the southern hemisphere. The former set includes the discovery of eight spectroscopic binaries, the latter the discovery of four.

The radial velocity of Antares is also discussed in the same bulletin. A comparison of the earlier with the more recent spectrograms of this star afforded a strong indication of variable velocity, which has been confirmed by new observations and the re-measurement of the old plates. A faint superimposed spectrum is indicated on some of the plates, but this is supposed to be due to the telescopic companion of Antares.

The Recent Maximum of Mira.—In the February number of *Knowledge and Scientific News* Mr. P. M. Ryves discusses a number of magnitude observations of Mira made during the rise to maximum brightness which took place in the latter part of 1906. The observational results, obtained on forty-two days between July 30, 1906, and January 10, 1907, showed that the magnitude on the former date was about 9.0, whereas by October 17 it had reached 7.0. A more rapid rise in brightness then set in, so that by December 2 the second magnitude was attained, that is to say, the light was increased about one hundred-fold in less than fifty days. For the nineteen days between October 26 and November 14 the rise in brightness was particularly abrupt, the star passing from the sixth to the third magnitude. From Mr. Ryves's results the actual maximum appears to have taken place about December 10, 1906 (J.D. 2417555), when the recorded magnitude, on the Harvard scale, was 1.85.

The United States Naval Observatory.—The report of the superintendent of the U.S. Naval Observatory for the year ending June 30, 1906, follows the usual lines of its predecessors. Rear-Admiral Asa Walker succeeded Rear-Admiral Chester as director in March, 1906. In many departments the ordinary routine work was greatly hindered by the preparations for the eclipse of August, 1905, and the absence of a number of the observers with the eclipse expedition. The final plans for a self-registering right-ascension micrometer, for use with the 6-inch transit circle, have been adopted, and the instrument is being made. Solar photographs were obtained on 168 days, and showed spots and faculæ on all but two days. With the meridian and equatorial instruments observations of the normal character were made, and the usual chronometer and time services were well maintained.

Sun-spots in 1905.—The results of the Greenwich measures of sun-spots for the year 1905 appear in No. 3, vol. lxvii., of the Monthly Notices (R.A.S.). The increase in spotted area during the year as compared with 1904 was 144 per cent., the mean daily area, 1191, was greater than that of 1883, but less than the corresponding areas for 1892, 1893, and 1894. The increase in area of the faculæ was about 48 per cent. The mean latitude of the spots during the year, about 13°, points to 1905 as being the year of maximum in the present spot-cycle, although the continued preponderance of the spotted area in the northern hemisphere corresponds with the condition obtaining some two years before maximum in the two preceding cycles. The outstanding feature of the year 1905 was the great number of abnormally large spots, one spot seen from January 29 to February 11 exceeding in area any other spot as yet measured at Greenwich.

No. xcvii. of the *Astronomische Mitteilungen* contains Dr. Wolfer's annual summary for 1905 of sun-spot frequency and heliographic distribution, with which he compares the results obtained from the measures of magnetic declination.

ITALIAN VOLCANIC ROCKS[1]

ALTHOUGH the Tertiary and Recent volcanic tract along the western side of the Apennines is classic ground to the geologist no less than to the historian, we still possess only meagre information concerning the many remarkable, and often unique, rock-types for which these Italian volcanoes have long been famous. A comprehensive and connected study of a large part of the assemblage by a well-qualified authority is therefore peculiarly welcome. Dr. Washington has devoted much attention to the subject both before and since the publication, ten years ago, of his "Italian Petrological Sketches."

"Comagmatic region" is synonymous with "petrographical province," and the author's reasons do not convince us of the necessity of abandoning a now familiar term. The Roman region is defined as extending from Lake Bolsena to the Phlegræan Fields, and probably few petrologists will dissent from the proposition that the community of characters among the volcanic rocks of this region points to a real genetic relationship of the several

Sketch Map of Italian Comagmatic Regions

Roman Region: V — Vulsinian District; Ci — Ciminian District; S — Sabatinian District; L — Latian District; H — Hernican District; A — Auruncan District; Ca — Campanian District; Ve — Vesbian Volcano; P — Phlegræan Fields; I — Ischia; 1 — Montecatini; 2 — Campiglia; 3 — Massa Marittima; 4 — Roccastrada; 5 — Monte Amiata; 6 — Tolfa; 7 — Cervetori; B — Berican Hills; E — Euganean Hills; Vu — Monte Vulture; Et — Etna

Tuscan Region

Venetian Region

Apulian Region

magmas. The author separates, though somewhat doubtfully, the smaller "Tuscan region" lying farther to the north and west, which we hope will be the subject of a future memoir. It can scarcely be denied, however, that a certain community of characters unites all the Italian volcanic districts on this side of the Apennines (with Monte Vulture in the mountain-belt itself), the resemblance being emphasised by contrast with the rocks of the Euganean Hills on the opposite side of the main orographic line.

The body of the memoir before us consists of two parts. The first is purely descriptive, the several rock types being treated in order, succinctly but thoroughly. The special features of this part are the quantitative element constantly introduced into the mineralogical descriptions, and the addition of a large number of new and carefully-made chemical analyses of the lavas. The peculiarity which has made the region famous in petrography is the abundance and variety of leucite-bearing rocks. The non-leucitic types are for the most part of trachytic affinities, though with a proportion of soda lime-felspar which caused the author (in his former papers) to distinguish them under the names vulsinite and ciminite.

The second part of the memoir, discussing the mutual relations of the associated rocks, is headed "Petrology" (the first part being "Petrography"). It would seem more convenient to use the name petrology for the whole science of rocks, including the descriptive branch (petrography) and the rational. The author gives an interesting discussion of the facts which he has brought together, and touches on the genetic problems which underlie those facts. In particular, he attempts a calculation of the average composition of the magmas for the several districts and for the whole region. In the central part of the region all the lavas carry leucite, basic leucite-tephrites and leucitites being largely predominant, while at the two extremities of the region the trachytic types are in greater force. No definite order of succession in time can be made out.

While taking care to make his work intelligible to the ordinary petrologist, Dr. Washington employs throughout the methods and terminology of the Quantitative Classification, of which he is joint author. The memoir thus written does, as he claims, serve to make that system clearer by showing it in actual operation, and this is an incidental gain, but, although it is here seen at its best, as applied to a cognate collection of types, most of which possess strongly marked characteristics, we do not find our fundamental objections to the new classification weakened by a closer acquaintance with it. If a rigidly quantitative, and therefore artificial, classification be desirable, which we do not concede, it might be sought in the actual mineral composition of the rock (here estimated in most cases) rather than in the imaginary composition which is called the "norm." In reading the descriptions and discussions it needs no very perverse fancy to construe many sentences as censuring Nature for departing from the "norm" or commending her for approximately conforming to it, and this air of artificiality must somewhat discount the usefulness of what is undoubtedly a very valuable monograph.

A. H.

INVERSION TEMPERATURES FOR AIR AND NITROGEN

THE Bulletin of the Cracow Academy of Sciences for December, 1906, contains a preliminary note, by Prof. K. Olszewski, on the determination of the temperature of inversion of the Joule-Kelvin effect for air and for nitrogen when subjected to different pressures. The apparatus used was similar in principle to that adopted in 1901 in determining the inversion temperature for hydrogen, but details had to be modified owing to the necessity of working at much higher temperatures. The table which follows shows the inversion temperature of the gas when allowed to expand from the initial pressure p (expressed in kilograms per square centimetre) to the pressure of the atmosphere. Above the temperature t a thermo-element showed a heating effect on expansion, whilst below this temperature a cooling effect was observed.

Air		Nitrogen	
p	t_i	p	t
160	+259	159	+243
100	249	126	238
90	244	102	233
80	240	90	228
70	235	80	223
60	226	68	217
40	198	55	205
20	124	30	163

It is seen that the inversion temperature is a continuous function of the pressure, confirming the recent theoretical views of Witkowski and Porter. The value of the in-

version temperature for air, however, calculated by Witkowski from the empirical formula of Rose-Innes, was +360°, whilst the van der Waals formula was found to require an inversion temperature of +500°, in the latter case, however, the calculation is based on the assumption of a small difference of pressure (1 atmosphere) accompanying the expansion, whilst the experimental values refer to expansion over a wide range of pressure. The shape of the curve for air connecting the inversion temperature with the initial pressure at which expansion occurs shows that below 80 atmospheres a rapid fall of the inversion temperature occurs as the pressure is diminished. Very little cooling effect is therefore to be anticipated with air allowed to expand from pressures below 80 atmospheres; such, indeed, is actually observed to be the case, liquefaction only taking place readily in the apparatus described by Prof. Olszewski in 1902, so long as the initial pressure does not fall below this limit.

STUDENTS IN GERMAN UNIVERSITIES

ACCORDING to the *Chemiker Zeitung*, the total number of matriculated students in attendance at the German universities during the present winter semester is 45,136, as against 44,942 last summer, and 42,390 in the preceding winter; five years ago the attendance was 35,518, ten years ago 30,043, twenty years ago 27,080, and thirty years ago, that is, in the winter 1876–7, it was only 17,457, upon which total the present number shows an increase of 27,679, or 159 per cent. It is of more than passing interest to compare the number of students at the different universities to-day with those of thirty years ago:—

	1906–1907	1876–1877		1906–1907	1876–1877
Berlin	8188	2490	Tübingen	1522	903
Munich	5567	1280	Marburg	1503	382
Leipzig	4466	3036	Würzburg	1407	1028
Bonn	2992	793	Jena	1275	439
Halle	2250	854	Konigsburg	1140	621
Breslau	1961	1219	Giessen	1097	318
Gottingen	1831	991	Erlangen	1056	474
Freiburg	1744	293	Kiel	877	219
Strassburg	1652	707	Greifswald	827	468
Heidelberg	1603	473	Rostock	645	156
Munster	1533	313			

The distribution of these students in the various branches of academic study is as follows:—

	1906–1907	1876–1877
Law students	12215	4835
Art students	10873	3874
Medical students	7035	3374
Mathematical and science students	6116	2009
Evangelical theology	2208	1518
Pharmaceutical students	1865	680
Catholic theology	1708	1164
Students of economic sciences and forestry	1235	155
Agricultural science	985	369
Dentistry	870	8
Veterinary Science (only matriculated at Giessen)	110	0

Against these numbers it is to be remarked that the large number of applied and pure science students attending the Technische Hochschulen is not included here, while the number of arts students is too high by nearly 1000, owing to the modern custom in the Prussian universities' returns of including among such students those whom they place under the tabulation heading "Sonstige Studienfächer der philosophischen Facultat."

Out of a total number of 45,136 students in attendance at German universities during the present winter half-year 4151, or 9·2 per cent., are described as foreigners, against 8·6, 8·4, and 7·5 per cent. in the preceding half-years. The absolute increase of 596 on the number for the corresponding semester of last year (namely, 3555) is almost exclusively due to an increase in the number of Russian students, who have increased from 1320 to 1890 in one year. Of the 3717 students belonging to European countries, 681 are from Austria, 341 from Switzerland, 144 from England, 139 from Bulgaria, 83 from Roumania, 61 from Servia, 58 from France, 57 from Holland, 53 from Luxemburg, 47 from Greece, 40 from Turkey, 33 from Italy, 32 from Scandinavia, 23 from Spain, 19 from Belgium, 9 from Portugal, and 5 from Denmark. From America, mainly from the United States, are 302; from Asia, chiefly Japanese, 113; from Africa, 13; and from Australia 6. The distribution of this foreign element at the universities is as follows:—

University	Foreign students Number	Per cent.	University	Foreign students Number	Per cent.
Berlin	1189	14·5	Giessen	84	7·6
Leipzig	662	14·8	Breslau	77	3·9
Münich	496	8·8	Würzburg	67	4·7
Heidelberg	259	16·1	Marburg	60	4·9
Halle	254	11·3	Tübingen	59	3·9
Jena	186	14·6	Greifswald	43	5·2
Gottingen	169	9·2	Erlangen	28	2·6
Freiburg	164	9·4	Rostock	13	2·0
Konigsberg	134	11·7	Kiel	12	1·4
Strassburg	96	5·8	Munster	11	0·7
Bonn	88	2·9			

These foreign students are taking as their chief studies:—evangelical theology, 185; Catholic theology, 34; law, 580; medicine, 1080; philosophy, languages, or history, 951; mathematics and science, 714; agricultural sciences, forestry, &c., 573; dentistry, 24.

STANDARD ELECTRIC GLOW LAMPS

THE report of the Engineering Standards Committee on the British standard specification for carbon filament glow lamps, which has recently been issued, is of great interest, more especially as it has been published at a time when so many important papers and discussions on carbon and metallic filament lamps are occupying the attention of men of science and engineers. The specification gives at the beginning a list of standards and definitions, and goes on to state what the committee has decided as to the tests a standard lamp shall comply with. A lamp of 12 candle-power is suggested in addition to the usual 8, 16, 25, and 32, and this should prove a very useful size; although it has already been used, it has not been kept as a stock lamp usually. The standard lamps are to be divided into two classes, having a useful life of 400 and 800 hours respectively, and all lamps purporting to be British standard lamps are to be marked with the trade mark or name of manufacturer, the standard mean horizontal candle-power, the voltage, and a reference letter in a circle, which is to show which class—whether 400 or 800 hours—the lamp is intended for. This reference letter is, we think, a mistake, as the ordinary consumer will not know to what it refers, and we do not see the objection to marking plainly on the lamp the useful life hours. The insulation resistance between cap and filament seems to us to be rather high (1000 megohms). The limits for mean horizontal candle-power and total watts, on the other hand, allow plenty of margin, but doubtless these will be reduced after the standards have come into force, which we understand they will do in July next. At present, however, we do not see that the ordinary consumer will benefit very greatly by the specification when it does come into force, for, as we pointed out a few months back, unless the borough councils or local authorities erect special testing laboratories where tests on lamps can be carried out by an expert for a very small fee, or even free of cost, the ordinary consumer will be in practically the same position as he is at present. Of course, the fact of his being able to ask for a standard lamp may tend to make the article sold him slightly better, and with truer candle-power and consumption figures marked on, still, we are afraid that, from the consumer's point of view, until he can get his lamps tested locally, not very much improvement will be seen. The report is, however, of very great interest to those connected with that branch of the electrical profession, and is certainly a long step in the right direction.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

THE Government of the French Republic has, by a decree of the Minister of Public Instruction and Fine Arts, conferred upon Prof J Wertheimer, the principal of the Merchant Venturers' Technical College, Bristol, the order of Officier d'Académie

DR DONALD MACALISTER, fellow and director of medical studies of St John's College, Cambridge, Linacre lecturer of physic, and president of the General Medical Council, has been appointed principal of the University of Glasgow in succession to the late Principal Story

M LIARD, Vice-Rector of the University of Paris, has informed the Paris Municipal Council that it is the intention of the University of London to return the visit made to it last year by the Paris University The representatives of the University of London are to arrive in Paris in the middle of May, and a luncheon will be given at the Hôtel de Ville to the members of both universities

MR F DARWIN has been nominated to represent the University of Cambridge at the celebration of the two-hundredth anniversary of the birth of Linnæus, to be held at Upsala in May Dr Hill, Dr A Caldecott, and Mr D H S Cranage have been nominated to represent the University at a federal conference on education, convened by the federal council of the League of the Empire, to be held in London on May 24 to June 1

IT would be difficult to find a more useful book for parents selecting a school for their sons than the "Public School Year-book" (Swan Sonnenschein and Co, Ltd price 3s 6d net), the eighteenth issue of which has just appeared Full particulars of all the schools represented at the headmasters' conference are given, and these are supplemented by much useful information about preparatory schools, the entrance to the professions, public examinations, and kindred subjects

WE have received from Washington copies of the reports of the librarian of Congress and of the superintendent of the library building and grounds for the fiscal year ending June 30, 1906 The amount expended on the library during 1906, exclusive of sums spent on printing and binding reached 117,500l During the same year the net accessions to the library were nearly 35,000 The librarian's report gives interesting particulars of numerous bequests and gifts to the library and information concerning the complete system of cataloguing which has been elaborated The second report deals with such matters as the cost of care and maintenance

HIGHER education in the United States continues to benefit by the generosity of public-spirited American men of wealth We learn from *Science* that an announcement has been made that Mr J D Rockefeller will endow the University of Chicago with 600 000l to maintain a pension fund, the institution having been excluded from the scope of the Carnegie foundation, owing to its denominational control It is also reported that Mr Rockefeller has agreed to give 400 000l for the endowment of a university for Louisville provided a similar amount is raised by those interested in the new institution The chair of chemistry at the University of Pennsylvania has been anonymously endowed by a gift of 20,000l Mr S W Bowne has given to Syracuse University a chemical laboratory, costing 20,000l Finally the packing interests of Chicago have offered to the University of Illinois the sum of 50 000l with which to establish in that city a veterinary college

MR J D ROCKEFELLER has given the General Education Board, which is designed to help educational institutions 6,400,000l for the purpose of assisting the work of the Board throughout the country Referring to this announcement, the New York correspondent of the *Times* remarks that the donation is believed to be the largest single sum ever given for a philanthropic purpose So far as is known, Mr Rockefeller has up to the present made donations for educational purposes amounting to a total of 18,000,000l, and he is believed to have given anonymously 6,000,000l more The General Education Board will now be in a position to aid educational institutions all over the United States No State universities share in its gifts, and in every case the Board endeavours to encourage institutions which may eventually come to be self-supporting rather than those dependent on charity for their maintenance

THE report of the higher education subcommittee of the London County Council, which was adopted at a recent meeting of the Council, recommends that certain grants be made to the governors of fifty secondary schools The total amount available out of the current estimates is 120,000l It is estimated that 11,945l will be required in respect of the building grants voted in March, 1906 The proposals amount to 74,825l, of which 2355l is for equipment Last year the corresponding figures were 66,745l, of which 3895l was for equipment This represents a gross increase of 8080l, of which about 6000l may be taken as the cost of the education of the increased number of the Council's scholars To make the comparison accurate, however this sum should be increased by 1789l, the amount of the grants paid last year, which for different reasons are not included in this year's list The net increase in aid, apart from the cost of the Council's scholars, is therefore under 4000l

DR M W TRAVERS, F R S, who is at present making a tour in India in connection with the Tata Research Institute of which he is the first director, has, the *Pioneer Mail* reports expressed disappointment at the standard required for degrees in science at Indian universities In chemistry the courses are defective, Dr Travers finds few of the universities introduce quantitative practical courses and the theoretical courses are hardly up to the intermediate standard of English universities The lack of suitable students among bachelors of science will be a drawback to research in the Tata Institute and may lead to a difficult situation Indian universities have hitherto confined their research courses to masters of arts or science who have received two years' special training after graduating The total number of research students in all the Indian universities is probably considerably less than twenty It is consequently feared that there may be a difficulty in supplying the Tata Institute with properly qualified students

THE report of the Departmental Committee on Education Rates, appointed in October, 1905 has been published as a Blue-book (Cd 3313) An important section of the report deals with expenditure on higher education—in this connection an elastic term including all forms of instruction other than elementary A summary relating to the rates required in 1905-6 by county and county borough councils for the purposes of higher education, shows that the councils of nineteen counties raised no rates for higher education at all and that seven county borough councils had the same unenviable notoriety Of the forty-three counties levying such a rate sixteen required something under 1d in the pound nineteen under 2d, seven (including the London County Council) less than 3d, and one between 3d and 4d Of sixty five councils of county boroughs one (West Ham) required more than 5d in the pound, three more than 4d but less than 5d, nine more than 3d but less than 4d six more than 2d but less than 3d thirty four more than 1d but less than 2d, and twelve less than 1d The sum of 2,477 327l was devoted in 1904-5 to higher education of the kind explained and of this amount 31 5 per cent was raised by rates 20 6 per cent was received from the Board of Education and 38 1 per cent was allocated from Exchequer contributions The report states as indeed is much to be hoped that the expenditure of local authorities in respect of higher education may be expected to continue to increase in amount Altogether, the Blue-book provides an abundance of useful information

THE fourteenth annual general meeting of the Association of Technical Institutions was held on February 8 and 9 in London The meeting was preceded by a luncheon given to the members of the association by the Clothworkers' Company Sir Horace Plunkett the president for 1907 delivered an address, during which he said that among the many admitted defects of our educational system there is one most hopeful sign—the evening technical institutes, of which we may be justly proud It is true

that their very success emphasises the defectiveness of the present condition of things in regard to higher technical training This condition is due to the difficulty of securing attendance at day courses in our many excellent institutions There has been some improvement in this respect, but the number of students taking systematic higher courses is lamentably small Sir Horace Plunkett is convinced that the tendency to bring the instruction in the evening technical institutes into the closest relationship with industrial requirements will go far to secure what is admittedly one of the most important desiderata to-day—the cooperation of employers and workers It must be frankly recognised that the *raison d'être* of the evening technical school is industrial efficiency, that the apprenticeship system under modern industrial conditions must fail to educate the young worker effectively, and that the evening technical school must now undertake some of the teaching previously conferred in the workshop The great usefulness of American technical institutions is due in a large measure to the individual interest taken in the students, not only during their attendance at the school, but during their subsequent career The following papers were read and discussed —The cooperation of adjacent authorities in the supply of higher technical education by Principal A F Hogg, of West Ham and monotechnic institutions, by Mr Charles Harrap of the St Bride Foundation Institute, London

SOCIETIES AND ACADEMIES

LONDON

Royal Society November 1 1906 —"The Nitrification of Sewage" By Dr G **Reid** Communicated by Prof Gotch F R S

The author gives an account of certain observations he recently made which point to the conclusion that by using fine-grain filter particles the depth of percolating filters may be greatly reduced A filter composed of ⅛-inch medium, which had been in constant use for three years, was tapped at four depths in such a way that samples could be collected to show the degree of purification effected at 1-foot intervals downwards, and the conclusions arrived at are based upon the analysis of numerous samples collected during a period of about twelve months, the delivery to the filter being constant throughout and at a rate of 200 gallons per superficial yard As regards the organic matter, both in suspension and solution in the septic tank effluent applied to the filter, the author found that the work of purification was effected at a depth of 1 foot from the surface, leaving very little work for the deeper layers to accomplish

The following are the means of the more important figures of analyses —

—	Parts per 100 000				
	Septic Tank	1 ft	2 ft	3 ft	4 ft
Solids in Suspension	7.60	0.25	0.09	0.14	0.00
Free Ammonia	1.716	0.036	0.020	0.009	0.043
Albuminoid Ammonia	0.340	0.052	0.037	0.031	0.027
Oxygen absorbed in 4 hours at 80° F	2.184	0.328	0.286	0.244	0.259
Nitrous Nitrogen	0.000	0.003	0.007	0.008	0.002
Nitric Nitrogen	0.00	2.07	1.99	1.85	1.99

As regards the carbonaceous matter, the oxidation appeared to be equally rapid for not only did the reduction in oxygen absorbed reach practically its maximum at 1 foot depth, but the air collected from the filter at different depths gave the following amounts of CO_2 per 1000 —1 foot, 19.5; 2 feet, 21.5; 3 feet, 20.0; 4 feet, 20.0 As regards the suspended organic solids, they are practically all retained within the first foot where liquefaction is effected (it is suggested by anaerobic organisms) In confirmation of this, the following mean figures of percentage loss on ignition of filter particles taken from different depths are given —6 inches 3.25, 1 foot, 0.99, 2 feet, 0.65, 3 feet, 0.53, 4 feet, 0·53

As regards the remarkable increase in the free ammonia in the samples from the lowest tray, it is suggested that the circumstance may be accounted for by a revival of anaerobic changes, the result of the asphyxiating effect of the products of combustion produced above

Anthropological Institute, January 22.—Annual General meeting —Prof W Gowland, president, in the chair —Address on the dolmens and burial mounds of the early emperors of Japan the **President.** It is extremely probable that the Japanese obtained the idea of raising mounds from the Chinese, the earliest burial mound in China dating from 1848 B C Little is known about the earliest Japanese mounds, but the later ones are always more or less large, and invariably contain either a sarcophagus or dolmen There is an extremely large number of these mounds in Japan, and Prof Gowland himself examined 406 It is of interest to note that the dolmens are always near the coast or in the basins of the larger rivers, which points to the fact that at the time of their erection the Japanese only occupied these districts, the other parts of the country being inhabited by the primitive aborigines—the Ainu The distribution of the early Imperial mounds is also of importance historically They are found in four districts, which goes to prove that at an early date the country had no central Government, but that there were at least four independent tribes each occupying one of the districts where the large Imperial mounds are found The date of these mounds is between the second century B C and the fifth or sixth of our era As to the mounds themselves, the Imperial ones are double, with a conical peak at one end They are all of very great size, and are terraced and moated In plan they are seen to be a combination of the square and circular varieties, but whether this has any significance is not known One interesting feature is that round each terrace a series of terra-cotta tubes—"Haniwa"—about 18 inches high and 15 inches broad, are set in rows They may have been placed there for structural reasons, or they may represent the wives, attendants, &c, who formerly were buried with the emperor This practice was discontinued in 2 B C, and by an Imperial decree terra-cotta figures were substituted for the human victims Many of these figures have been found and in some cases they terminate in a "Haniwa" The largest of the Imperial mounds are in the central provinces, the largest of all is 2000 feet long and covers approximately an area of eighty-four acres The interment is always in the conical peak of the circular part of the mounds They are, as a rule entirely artificial but occasionally a natural eminence has been turned to account

Physical Society, January 25 —Prof J Perry, F R S, president, in the chair —The strength and behaviour of brittle materials under combined stress W A **Scoble** The results described in the paper are a continuation of a series obtained from tests on a ductile material The bars were of cast iron, ⅞-inch diameter, 30 inches between the bending supports, subjected to bending and twisting to fracture The maximum principal stress and the maximum shear, calculated on the assumption that there was no yield, each varied about 40 per cent Plotting the corresponding bending and twisting moments, the points lie on an ellipse, the twisting moment being about 3000 lb inches, and the bending moment 2200 lb inches at fracture In all cases, except that of simple bending, the fracture was a spiral, completed by a part making a small angle with the axis and invariably coming under the knife-edge —Recent improvements in spectrophotometers F **Twyman.** The paper deals with a form of Hüfner spectrophotometer designed in 1904, and consists of two parts —(A) The evaluation of the errors due to the polarisation produced by the dispersion-prism and by the Hüfner rhomb which brings about the accurate juxtaposition of the two beams of light the intensities of which are to be compared, and the method by which in the recently constructed instruments it is arranged for these effects to neutralise one another (B) The use of the instrument as a spectropolarimeter by placing in the space between the dispersion-prism and the second Nicol the media the optical rotations of which it is required to measure

Challenger Society, January 30.—Mr. E. W. L. Holt in the chair.—Fishes captured by the Marine Biological Association's fishery steamer *Huxley* in November, 1906, at the channel entrance from the Bay of Biscay: L. W. **Byrne.** The collection was chiefly interesting as providing records of species already known from deeper water, *e.g.* *Synaphobranchus pinnatus*, and *Scopelus glacialis*, *S. punctatus*, and *S. crocodilus*. Attention was also directed to specimens of the little-known *Onos biscayensis* and the recently described *Pteridium alleni*.—The Decapoda collected by H.M.S. *Research* in the Bay of Biscay, 1900: S. W. **Kemp.** The chief interest of this collection was in a fine series of *Acanthephyra purpurea*, which ranged from the length of 4.3 mm. up to an adult of 81 mm. Unlike *A. debilis*, in which Coutière has shown that the larva is hatched with peræopods, uropods, and pleopods fully formed, this closely allied species leaves the egg as a Zoæa. The series of larvæ was fully described and figured, and shows a remarkable reduction at a certain stage of the cornea and rostrum, followed by their subsequent growth. Other interesting captures were *Sergestes arcticus*, *Gennadas parvus*, and *Acanthephyra debilis*. The author also described and figured an unknown larva allied to Caricyphus of Spence Bate.

Society of Chemical Industry (London Section), February 4.—Mr. R. J. Friswell in the chair.—Chemical composition of some motor-tyre rubbers: Dr. P. **Schidrowitz** and F. **Kaye**. The authors conclude (1) that in many cases tyre trouble is directly referable to chemical defects (such as over or under curing, unsuitability of the quality of the rubber, excess of mineral matter, &c.) of the rubber mixings; (2) that manufacturers are by no means agreed as to nature and quantity of the various ingredients and conditions of manufacture to be employed; (3) that it is apparent from the widely divergent results obtained in some cases with tyres of the same size and make that the process of manufacture is not always conducted on sound scientific lines, but, on the other hand, they point out that some of the results of their investigations indicate that even and constant quality may be obtained by adequate supervision of manufacture.—Composition of some new crude rubbers: Dr. P. **Schidrowitz** and F. **Kaye**. The authors give the results of examination of rubbers from the newer sources of supply, such as Ceylon, Uganda, and Malaya, and also of a sample of *Castilloa elastica* from Mexico. The results of experiments on a series of Ceylon biscuit rubbers distinctly support the view that it is a mistake to turn out rubber in thin biscuit form, and the authors make some observations on the apparent nature of the changes produced in rubbers prepared in this manner. They also describe a modification of the Ditmar method of analysis of crude rubbers which they have devised, and give some preliminary figures referring to the nature of the proteids, resins, and mineral matters in some of the rubbers examined.—Sources of carbon dioxide in the determination of nitrogen in organic compounds by the absolute method: C. **Young** and B. **Caulwell**. The authors described a modification of Theile's apparatus (*Annalen*, 1889, 253, 242) for the evolution of carbonic acid in an external generator. The design of the mercury trap and safety tube are novel. The carbon dioxide produced is claimed not to contain 0.1 c.c. of air per 5 litres.

PARIS.

Academy of Sciences, February 4.—M. A. Chauveau in the chair.—The secretary announced to the academy the death of Prof. Mendeléeff.—Researches on the solar atmosphere. Vapours with dark lines and clusters of particles: H. **Deslandres** and L. **d'Azambuja**. A detailed account of the work done at the Observatory of Meudon during 1906 with various forms of apparatus.—Autopsy of the African elephant "Sahib" which died on January 29 at the Museum: Edmond **Perrier**.—Determinism of the superiority of the energy expenditure due to the assimilation of albumenoid foods: A. **Chauveau**. The author's experiments are described in detail. Of the numerous conclusions drawn from these results, the most important is that it is necessary to give up the use of the heat of combustion as a guide in the theory of food.—A new contribution to the study of trypanosomiasis of the Upper Niger: A. **Laveran**. A study of a new species closely allied to *Trypanosoma dimorphon*, arising from the blood of an infected sheep. A close comparison of *T. dimorphon* with the new organism shows that the two are not identical, and the name *T. pecaudi* is proposed for the new species.—The relation between falls of barometric pressure and the evolution of fire-damp in mines: G. **Bigourdan.** A comparison of the times of the colliery explosions in the Lens and Saarbruck basins on January 28 with the heights of the barometer shows that here, as in other cases, the explosions occurred at the time of a rapid fall of the barometer following a long period during which the readings of the barometer had been high.—Prince Roland Bonaparte was elected a member in the place of the late Raphael Bischoffsheim.—Some new variable stars with very rapid variations in light intensity: Jules **Baillaud**. In the photography of the chart of the sky the negative receives small successive displacements at intervals of thirty minutes, so that each star is represented by three contiguous images. These images will be similar if the condition of the sky has not changed, different if it has varied, but in the latter case all the images will be affected similarly. In some of the photographs obtained at Paris during 1906 several of these triple images vary considerably in the intensity of the images, and two at least of these cases appear to be due to very rapid variations in the brightness of the star. In one instance the three images are respectively of magnitudes 14.5, 13, and 12.7. Of the forty plates examined this year by MM. A. Boinot and J. Baillaud, containing more than 50,000 stars, only three other stars have been found exhibiting this peculiarity, and two of these are due to a grain of dust on the plate.—The quadrature of curved surfaces: Zoard **de Geöcze**.—The comparative study of helices and aeroplanes: P. **Tsoucalas** and J. **Vlahavas**.—The refraction of compound gases: Jules **Amar**. The author examines the proposition that the refraction of a compound gas is the sum of the refractions of the atoms which enter into the molecule, and shows that this proposition holds within the range of experimental error.—The resonance phenomena in the case of transformers with open magnetic circuit, and their utility in the production of strong electric sparks: G. A. **Hemsalech** and C. **Tissot**. Resonance effects are generally avoided in alternating-current circuits on account of the harmful results on the insulation, but there are certain cases in which there is a considerable advantage in establishing resonance, and one of these is the production of powerful electric sparks. An account is given of the construction of a coil in which this resonance effect is utilised. A transformer of the type described is useful not only in spectroscopy, but also in wireless telegraphy.—Experimental researches on dielectric solids: Louis **Malclès**.—An attempt at a theory of phosphorescence and fluorescence: J. **de Kowalski**. A development of some views of Prof. J. J. Thomson on the production of light under the influence of electric discharges. The theory is in general agreement, both qualitatively and quantitatively, with experiment.—The molecular weights of various gases calculated by the method of critical densities: Daniel **Berthelot**. Regarding the correction for the compressibility of a gas, the author points out that it is not a matter of indifference which formula is used for the variation of pv. This expression has been taken as a linear function of the density or of the pressure; the former is correct. The atomic weight of chlorine, deduced from the density of hydrochloric acid, falls between 35.454 and 35.478; that of sulphur, from sulphur dioxide, between 32.050 and 32.064.—The ethyl ether oxide of *αα*-dichloro*iso*propyl alcohol and on dibromoacetic aldehyde: P. **Freundler**. A preliminary notice indicating the line of work on which the author is engaged.—Some reactions of sodium amide: Louis **Meunier** and J. **Desparmet.** Sodium amide reacts with ethylene bromide, the products being acetylene, ammonia, and sodium bromide. With chloroform the reaction starts with difficulty, but once started becomes explosive, ammonia together with a mixture of sodium chloride and cyanide resulting.—The application of sodium amide to the preparation of diphenylbenzylamine, sodium diazo-

amidobenzene, and the sodium derivative of ethyl malonate is described —The composition of the plant juices extracted from stems and leaves G **André**.—The chemical composition of the Koch bacillus and its binding material Relation with resistance to acids Jules **Auclair** and Louis **Paris**. The fatty matters were extracted by successive treatments with alcohol, ether and chloroform, petroleum ether alone being incapable of extracting the whole of these substances These fatty matters, the protoplasm, and cellulose all give the Ehrlich reaction —Autopsy of the African elephant "Sahib," which died at the Museum on January 29 Mme Marie **Phisalix** The death resulted from an accidental chill, leading to inflammation of the lungs, there being no sign of any chronic disease —A new view of the Blastodinidea (*Apodinium mycetoides*) Edouard **Chatton** —The chain of the Puys and the lesser Puys Ph **Glangeaud** —Note on the Palæozoic strata of the eastern edge of the Central Plateau Albert **Michel-Lévy** —The direction of the earlier folds in the central and eastern Pyrenees Léon **Bertrand** —The age of the Eocene deposits of the Armorican massif and of the Ronca zone Jean **Boussac**.

INDIAN TREES

Indian Trees Being an Account of Trees, Shrubs, Woody Climbers, Bamboos and Palms Indigenous or Commonly Cultivated in the British Empire By Sir Dietrich Brandis, K C I E, F R S Pp xxxiv+767 (London Archibald Constable and Co., Ltd, 1906) Price 16s net

SIR DIETRICH BRANDIS is much to be congratulated on the completion of this very important work on the forest trees and shrubs of British India, and its appearance will be hailed with great satisfaction by all Indian forest officers and by many others who are interested in the botany of that country

The chief value of this work consists in its comprehensiveness as a classified and descriptive list of all the different kinds of trees and shrubs of actual or possible value to the forester The inclusion of species belonging to the latter category is of importance, because, as the author remarks —

"Quite unexpectedly a shrub, a climber, a bamboo or a tree may be found to be of considerable importance from a forester's point of view, and he should then have easy means of identifying the species in question"

Moreover, the value or importance of many trees and shrubs is apt to vary very considerably in different parts of India The book will also, by reason of its comprehensiveness, be of great assistance as a basis for the preparation of local forest floras The "Forest Flora of North-West and Central India," which was commenced by the late Dr Lindsay Stewart in 1869 and completed by Sir Dietrich Brandis in 1874, has always been regarded as a model example of what a local forest flora should be If on this pattern a series of such works could now be undertaken for the more important forest regions in India, the utility of the present work would be realised in the process of their preparation, and the difficulties in the way of identifying trees and shrubs would be greatly lessened by reason of the limited number of species The literature of Indian forest botany is very considerable, but local forest floras, with the exception of Gamble's "List of Trees, Shrubs and Large Climbers of the Darjiling District," Kanjilal's "Forest Flora of the School Circle," and Talbot's "Systematic List of Trees, Shrubs, &c, of the Bombay Presidency," are more or less out of date

The number of trees and shrubs described in this volume amounts to more than 4400, the flora of Ceylon not being included As this list of woody plants represents about one-fourth only of the total number of flowering species known to occur within this area, some idea can be obtained of the extraordinary richness and variety of the vegetation of British India taken as a whole The following extract from Sir Joseph Hooker's most interesting "Sketch of the Flora of British India"[1] contains a brief and clear explanation of the manner in which the main characteristic features of the vegetation were brought about —

"The Flora of British India is more varied than that of any other country of equal area in the Eastern hemisphere, if not on the globe This is due to its geographical extension, embracing so many degrees of latitude, temperate and tropical, and to its surface rising from the level of the sea to heights above the limits of vegetation, to its climates varying from torrid to arctic, and from almost absolute aridity to a maximum of humidity, and to the immigration of plants from widely different bordering countries, notably of Chinese and Malayan on the east and south, of Oriental,[2] European, and African on the west, and of Tibetan and Siberian on the north"

Mr Gamble, in his "Manual of Indian Timbers," estimates the total number of trees and shrubs (including woody climbers), which constitute the forest vegetation of the whole of India and Ceylon, to be 4719 If to these were to be added the more or less established species introduced from other countries, and allowing for a certain number of shrubs and woody climbers which have not been included in the estimate, a total of 5000 species would probably be reached

Some interesting remarks will be found in the introduction to Sir Dietrich Brandis's book on the geographical distribution of forest trees in India, a subject which, by reason of his extensive journeys and practical knowledge of the country, he is fully qualified to deal with Other important topics are briefly alluded to, chiefly as being problems requiring further investigation, such, for example, as the anomalous wood-structure of some kinds of trees and woody climbers, the tendency of certain gregarious species of trees to form pure forests, the periodic flowering of some gregarious species of bamboo and Strobilanthes, &c, and another subject which has engaged the author's attention from time to time relates to the production of permanently dwarfed trees and shrubs by the action of periodical jungle fires

The facilities provided in this book for the identification of the species are —(1) The synopsis of natural orders on pp xxv to xxxii of the introduction As the determination of the natural order is very frequently the most difficult part of the operation in the attempt to identify an unknown plant, it would have been satisfactory if more assistance could have been given by means of keys for each of the larger groups of orders belonging to Thalamifloræ, Calycifloræ, Gamopetalæ, and Monochlamydeæ (2) The keys to genera and species are quite satisfactory, and will be very helpful, (3) the index to vernacular names on pp 723–736, and (4) the illustrations, which consist of 201 figures interspersed throughout the book, many of these are very excellent portraits, and cannot fail to be of assistance towards the identification of what they represent

The natural orders are arranged in accordance with the "Genera Plantarum" of Bentham and Hooker,

[1] See in descriptive volume of the "Indian Empire" in the new edition of the "Gazetteer of India".
[2] In the sense of Boissier's "Flora Orientalis."

with one important exception, viz that the Gymnosperms are placed after the Monocotyledons In regard to genera and species, the "Flora of British India" has for the most part been followed

The descriptions of the commoner and more important species are printed in large type, and the information regarding them is given in three separate paragraphs The botanical name, the references to other books, and the vernacular names occupy the first paragraph, the second contains the description, and in the third, printed in smaller type, will be found the distribution of the plant in and beyond India, the time of flowering, and other information The botanical descriptions occupying the second paragraph though sometimes rather brief, are very much to the point There is, however, a want of uniformity in the punctuation, which tends in many instances to prevent the essential points of the description from catching the eye The use of a different type for the names of the principal organs such as calyx, corolla, stamens, ovary, &c, would have answered the purpose to some extent

The order Dipterocarpaceæ, which contains some very important timber trees, and others which yield valuable oils and resins has been specially studied by the author[1] In this book he describes nine genera and thirty-seven species Of the large family of Leguminosæ, fifty-one genera are included The oaks number thirty-seven species, the majority of which are restricted to the eastern Himalaya, Burma, and the Malay Peninsula, only seven extend to the western Himalaya, and not one has been recorded from the western peninsula Of palms, twenty genera and eighty-nine species are described The bamboos, which constitute a distinct tribe of the large and important family of grasses, have been very carefully done, fourteen genera and 102 species are mentioned Of the Coniferæ, nine genera and twenty-one indigenous species are described

A serious drawback in the get-up of this book is its excessive weight Having decided to use such a very heavy paper, it might yet have been arranged to divide the book into two equal-sized volumes This would have made each volume so much more convenient for handling than is the present book

J I D

A HANDBOOK TO THE MICROSCOPE

The Principles of Microscopy, a Handbook to the Microscope By Sir A E Wright, F R S Pp xxii+250 (London Archibald Constable and Co, Ltd, 1906) Price 21s net

THE author of this book is a skilled pathologist, and, therefore, necessarily a practical master of the manipulation of a microscope, at least in the case of transparent objects He has probably arrived at his views on the microscope by prolonged and varied practice, and by independent thought, rather than by studying the work of others He thinks the reader may find a grievance in the number of newly-coined words which he employs, but in a special subject no one should object to technical terms, without which science would indeed involve circumlocution, so long as a new technical term is carefully defined

Sir A E Wright labours under heavy self-imposed difficulties He always seeks to avoid a mathematical sign, the use of which as a substitute for speech can be defended, he says, "only in the case of the inarticulate classes of the learned" He ignores the fact that speech, whether in sound or in black and white, is as much *sign* as mathematical expression is sign, and nothing like so accurate

The reader of the book may therefore profitably bear in mind that the work is an exposition of the author's own views and explanations of results which often are unquestionably true but sometimes admit of doubt

The book is full, very full indeed, of beautifully executed diagrams, but conclusions are rather hastily drawn from them, and the reader is often left to derive his proof from due consideration of them rather than from detailed explanation We can well understand that a beginner will not be quite satisfied, but we recommend him to persevere, as he will certainly find many practical rules as to the use of condensers in variously illuminating microscopic objects, and experiments illustrating these rules in a very complete way, plainly described and easily executed A small diffraction grating is supplied with the book

The first five chapters are devoted to the consideration of the object, its visibility, and the differentiation of its details as depending upon its preparation in mounting and staining, and upon its illumination The author strongly and reasonably urges the view that it is from this side of the microscopic problem that important new discoveries will spring, rather than from improvements in technical optics To differential staining he prophesies a valuable field of work in the future

The second part of the book treats, in what seems to us an original way, of the microscope itself and of the optical matters connected with it The author conceives the passage of light through a lens system as divided up into vistas composed of cones of light The object, a small one, is at the vertex of a cone the base of which is the aperture of the first lens encountered The second cone has the same base as the first, but its vertex is in the first image The vista is completed at the real image, even if two lenses are employed before its formation We thus have the opening limb and the closing limb, the pole of origin and the terminal pole, and the waist, of a vista, introduced as technical expressions One vista may succeed another, and we may have a *catena* of vistas Thus we may have a condenser vista starting with the source of light and terminating at the stage, an objective vista beginning at the stage and ending between the lenses of the Huyghenian eyepiece, and an eyepiece vista starting at the last-mentioned place and ending on the retina of the eye, forming a catena of three vistas

This plan has the advantage of representing

[1] See in Engler and Prantl 'Pflanzenf' vol iii, part vi, also in Journ Linn Soc, vol xxx, p 1

graphically many of the properties of a train of lenses, especially points of magnification and aperture, but it must be used discreetly The author has himself been betrayed into an erroneous conclusion by means of it If the origin of such a catena is a point of light, and a small opaque disc is inserted in the opening limb, the lane of darkness succeeding it will follow the same rules of formation as the cone of light, i e it will be a succession of cones having bases at the apertures and vertices at the images One base is the conical projection merely of the previous one Now Sir A F Wright is rather prone to overrate the resemblance between projections and images He calls the similitude of a candle shining through a small hole upon a screen an image That is not the sense in which the word is technically employed An image is always a focussed image, though the qualification is not invariably stated But the confusion of the two ideas leads the author into language which cannot be interpreted otherwise, we think, than as implying that every detail in one aperture, say a fleck of dust, is repeated as a genuinely focussed image situated at succeeding apertures It is only a projection that takes place in such a case, and it would occur equally well at any plane along the line, and when the source of light has finite dimensions, even this strictly defined projection will not occur This idea that everything in one aperture is *focussed* in succeeding apertures leads the author to more than one conclusion which, if we read him aright, is not sound

An example of error arising really from the neglect of the focussing idea occurs in the author's justification, for it is not a proof, of the expression for the numerical aperture, in so far as it increases with the index of refraction of the external medium In one of the diagrams (p 74) the final surface of a convex lens is drawn as a plane, and in that case the excentric ray of a convergent beam will not intersect the axis if it finds itself in water or in oil, at a point so close to the lens as if air were the medium in which it emerges That is true, but it is no proof or even illustration of the point under consideration, which is the effect of the index upon the numerical aperture This will be manifest by supposing the lens a convex meniscus with the second surface concave, and the origin of light to be at the point which is conjugate to the centre of curvature of the second surface Then the light, both immediately before and after encountering the final face, will be normal to it, and an emergent ray will intersect the axis at the same point whether the surrounding medium be air or water But the numerical aperture would still be affected by the medium

The aperture question seems, indeed, a stumbling-block to the author He knows as well as others do the connection between the radius of the false disc and the numerical aperture, and he rightly defines the latter, but his proof of the proposition at pp 110, 111, would make the numerical aperture proportional to the tangent (instead of the sine) of the semi-angle of the cone of light

The author has constructed an instrument to which he has given the name eikonometer, not a very happy one, for its object is, not to measure images generally, but by measuring certain images to arrive at magnifying powers The principle which is not so new as the author supposes, any more than the constructed instrument, is the fact that if two lenses are placed upon the same axis at any convenient distance apart, the first principal focus of one is conjugate to the second principal focus of the other, and the object bears to the image the same linear proportion which the focal lengths of the two lenses bear one to the other Hence, if the object be of known dimensions and its image be measured and therefore also known, and if one of the focal lengths be known, the other is also at once determinable The actual focal length of an entire microscope may thus be and has been determined in one observation The magnifying power is usually taken as the number resulting from the division of 250 by the focal length in millimetres but this is an arbitrary rule which presupposes that 250 millimetres is the least distance of distinct vision which is certainly not the case universally The author does not use the eikonometer quite logically In finding the focal length of a microscope his instruction is, *first* to focus the microscope in the usual way upon a scale of known dimensions situated on the stage, then to place the eikonometer over the eye end of the instrument and to read off

The instruction should be *first* to place the eikonometer in position, and *then* by means of the ordinary focussing arrangement of the microscope bring the image of the scale on the stage into position at the scale of the eikonometer, and then read off

The author thinks himself at issue with Abbe in the conclusion drawn from the grating experiment of the latter This arises through a misapprehension, and the experiments which the author cites do not affect the conclusions which Abbe reached

THOMAS H BLAKESLEY

THE CRUSTACEA OF DEVON AND CORNWALL

The Crustacea of Devon and Cornwall By Canon A M Norman, F R S, and Dr Thomas Scott Pp xv+232, 24 plates (London William Wesley and Son, 1906) Price 1l 4s net

STUDENTS of British carcinology owe their thanks to Dr Norman and Dr Scott for the first appearance of a volume embracing the wide field of our indigenous crustacean fauna, as hitherto recorded in the Devon and Cornwall area Dr Norman's researches in this district, extending over a period of more than fifty years, are too well known to need mention here, and the publication of his records is a welcome addition to our literature The introduction contains some interesting comparative tables on the distribution of species north and south relative to the area with which the work is concerned The body of the work comprises an enumer-

ation of the species, with synonymy and records of occurrence, and occasional descriptive notes, with twenty-four plates

The laborious task involved in gathering together the extant records of those who have in past years contributed to our knowledge of the British Crustacea must not be underestimated, but it is much to be regretted that the authors did not at the outset, in the compilation of such a work, bear in mind more fully the need of the student to whom, if not already an expert, a mere enumeration of our crustacean fauna can be of little assistance in his work We would much have wished that the authors, with their wide knowledge of the group, had seen well to combine with their work a system of synoptic tabulation, whereby the volume might have been made of more practical service to the student The portion dealing with the Copepoda bears witness to the extreme care bestowed on this part of the work Records of occurrence are given in interesting detail throughout, and the many new species for the discovery of which we are indebted to the authors are very fully described, their distinctive characters being well exhibited in the accompanying plates We would wish that the same careful system had been followed throughout the remainder of the volume, where records of observation are very bare and indefinite, rarely with dates, and distinctive characters are for the most part entirely omitted There seems, for example, no reason why two succeeding species of Galathea should be dismissed with the bare entry "common," or why, at the opening page, the three species of Ebalia should be passed over without comment, despite the precarious identity of one of them, which some of us still hope to retain

The retention of errors like "Daphina" (p 102), "Reptort" (p 185), and two authors' names, in a footnote to p 202, both of them mis-spelt, is a disfigurement to the text *Squalus galeus* and *S acanthias* (p 74) are inconsistent with *Galeus vulgaris* and *Acanthias vulgaris* elsewhere "Whiting-pout (*Gadus fuscus*)," on p 216, is misleading On p 192, for the host of *Asterocheres suberitis* the name *Suberites domuncula* is employed, a sponge which, properly named, does not, so far as we know at present, exist in our fauna

Including eighty-six inland forms, 808 species of Crustacea are recorded for the area concerned, the marine Copepoda and Amphipoda numbering 274 and 142 respectively As compared with these figures, Dr Scott has previously recorded for the Clyde district 855 species, the Sympoda, Amphipoda, and Ostracoda being responsible for the difference

While feeling a certain sense of disappointment at the general scheme of the work, we are much indebted to the authors for placing at our disposal a valuable record of observation which it is hoped may some day contribute largely to the drawing up of that much-needed work, a handbook to the British Crustacea

L R C

PALÆONTOLOGY FOR STUDENTS.

Die Leitfossilien aus dem Pflanzen- und Thierreich in systematischer Anordnung By Dr Johannes Felix Pp x+240, illustrated (Leipzig Veit and Co, 1906) Price 6 marks

SINCE the publication of the late Prof Karl von Zittel's exhaustive "Handbook of Palæontology," several smaller books have been compiled on the same plan The encyclopædic method, which is appropriate enough for a large work of reference, has been adopted in the less pretentious text-books for the use of elementary students who desire only a general acquaintance with fossils The result is that instead of teaching fundamental principles and broad outlines, these little books provide an overwhelming series of disconnected facts which weary the memory, and palæontology is not only discredited as a mental exercise, but also becomes unpopular with those who really need its guidance while pursuing allied branches of science

Another of these small books has just been laboriously compiled, with numerous illustrative figures, by Dr Johannes Felix, the well-known palæontologist of Leipzig It is neither better nor worse than its predecessors, and illustrates well the disadvantages of the dictionary form for elementary teaching For instance, among Carboniferous plants, one of the most important groups is that of the Pteridosperms, bearing well-developed seeds in association with fern-like foliage Dr Felix's brief catalogue may enable a student to distinguish a Neuropteris from a Pecopteris, and so forth, but it does not give the least clue to the real interest or meaning of these fossils Again, among vertebrate animals, the theromorphous reptiles are of fundamental value is pointing out the direction in which the cold-blooded land animals passed into the warm-blooded mammals The book before us, though pretending to deal with fossils at varying lengths according to their degree of importance, does not even mention that the Theromorphs were chiefly land animals It merely catalogues, with a desultory statement, the skull of the sea-reptile Placodus, which is probably not a Theromorph at all, and certainly gives no conception of the nature of the group in question

Still worse, this compilation and condensation of matter from previous text-books destroys all effort to bring the subject up to date It is much simpler to select a few miscellaneous facts from an exhaustive collection, and to purchase a set of electrotypes in a wholesale manner, than to make a judicious use of original memoirs and prepare new drawings to illustrate the science as it is now understood We therefore look in vain among the "Leitfossilien" enumerated by Dr Felix for any allusion to the European Lower Palæozoic fishes, the South African Triassic reptiles, the Egyptian Tertiary mammals, and the remarkable discoveries in South America, which have revolutionised many ideas in palæontology during the past two decades Students may be able to name a few common European fossils if they happen to have

the patience to pore over this new book, but they will not gain much insight into the science these fossils illustrate, and their enthusiasm must be unusual if they retain any desire to proceed with palaeontological research when they have completed their course A S W

THREE ASPECTS OF ELECTRICAL ENGINEERING

Applied Electricity a Text-book of Electrical Engineering for Second Year Students By J Paley Yorke Pp xii+420 (London Edward Arnold, 1906) Price 7s 6d

The Electrician Primers Edited by W R Cooper Three volumes in one Vol i, Nos 1-24, Theory Vol ii, Nos 25-55, Traction, Lighting and Power Vol iii, Nos 56-80 Telegraphy, Telephony, Electrolysis and Miscellaneous Applications (London *The Electrician* Printing and Publishing Co, n d) Price 10s 6d net

Electricity of To-day its Work and Mysteries described in Non-technical Language By Charles R Gibson Pp xiv+347 (London Seeley and Co, 1907) Price 5s net

THE three books before us suggest an interesting comparison of three points of view from which any applied science can be regarded Each covers, or attempts to cover, in a more or less summary fashion, practically the whole subject of electrical engineering, but as each appeals to an entirely different audience, the difference in method of treatment is necessarily very marked Mr Yorke's volume is written for the student who proposes to become an electrical engineer, the genuine professional, whose chief assets must be knowledge and brains The readers of the *Electrician* Primers will mostly be found amongst artisans, amongst the class not unjustly distinguished from electrical engineers by the name of electricians, people who require a fair amount of knowledge, but who can get on with a very limited amount of understanding Finally, Mr Gibson's book makes its appeal directly to the general public, or to that section of it which shows an intelligent desire to keep abreast of the times and is not content to utilise the advantages of civilisation without some attempt at appreciating the manner in which they are obtained

The great necessity for the professional engineer in his college training is to obtain a sound foundation on which to build by means of future experience Facts are easily learnt and as easily forgotten, whilst even if remembered they are likely to prove of but trifling value in actual practice No man can say when he is at college what branch of his profession is going to occupy his future, and it should be the aim, therefore, of any second year's course to impart a sound knowledge of the way in which the fundamental physical principles of electricity and magnetism are utilised in the practical applications of electrical engineering Mr Yorke has kept this point of view clearly before him in the book under review, and has succeeded on the whole very well in elucidating the connection between theory and practice There is no question, however, but that the value of a book of this kind depends almost entirely on the lectures and laboratory work that accompany it Text-books alone are so incapable of giving sound instruction in electrical engineering that one is almost justified in maintaining that to criticise them apart from the course with which they are to be used is idle The best that can be said is that the book would serve as a very useful model on which to base a second year's course of instruction It is perhaps, unwise that manufacturing methods should be described, in one or two instances this has led to mistakes which might have been avoided

To attempt a detailed criticism of the *Electrician* Primers would be to write a volume as bulky as that which they themselves form They range over such diversified subjects as "Curves and their Use," "Electric Railways," and "Photo engraving," to quote but a few examples Each primer forms a small handbook, and the artisan engaged in any particular branch of work would gain a fair insight into the *raison d'être* of his various operations by the study of those primers dealing specially therewith As a reference book also the complete set should prove useful The electrician occupied with tramways may occasionally find it necessary to know something about arc lamps or telephones, and in such cases the rough general information he requires could probably be obtained from these primers The whole ground of electrical engineering is covered very completely by the series

The correct person to review Mr Gibson's book is a member of the general public and not an electrical engineer, as the principal questions to be answered are, Is it intelligible? and Is it interesting?

It is a hard task to describe some of the more complicated developments of electrical engineering in simple, non-technical language, and to avoid incorrectness in the search for simplicity Mr Gibson has, however, accomplished this task with remarkable skill, and for many passages deserves to be sincerely congratulated There is too great a tendency, perhaps, to the relation of amusing little anecdotes which do not teach much, and to what may be described as sensationalism, but this is very natural and perhaps excusable The interest of the layman, no doubt, requires to be sustained by such illustrations as the photograph of a church wrecked by lightning, or of an attractive young lady making afternoon tea with an electric kettle But neither of these pictures has much educational value To cavil is, however, ungracious, the more the public can be interested in electricity the better for the whole trade and profession, and Mr Gibson's book will undoubtedly help on the work of progress One is apt to laugh at "popular" science, but Mr Yorke's students and the *Electrician's* artisans would all be amongst the unemployed without the market which Mr Gibson helps to provide MAURICE SOLOMON

OUR BOOK SHELF

Penrose's Pictorial Annual. The Process Year Book for 1906–7. Edited by William Gamble. (London: A. W. Penrose and Co., Ltd., n.d.)

THIS valuable and beautifully got-up volume surpasses, if possible, its predecessors. In the last few years the colour process has been rapidly coming to the front, and the present issue of this annual gives the reader an excellent insight into the good quality of the results which may be secured by the best processes of the day. The editor's task has evidently been no light one to include in this volume the wealth of material that is available, but the reader will be more than satisfied when he peruses it himself.

The arrangement of the book is the same as in former years. A most interesting series of articles dealing with process work and allied subjects is contributed, and the names of the authors are a sufficient guarantee for them. Thus, to mention only one or two cases, the editor gives a brief but clear account of the recent progress in process work, while Major-General Waterhouse describes the work of M. Léon Vidal, who, as he says, was a man who "fully recognised the educational value of photography," and who did much for its development, especially in the direction of photomechanical work, and the practical application of permanent printing processes for book illustration. M. Vidal's last contribution to this annual is contained in the present volume, and is entitled "The Future of Colour Photography when Autochrome Plates come into General Use."

Turning from the text to the illustrations, we have here also much food for thought. The frontispiece is an admirable engraving of Charles I. by the Rembrandt Intaglio Printing Co., Ltd. Of the numerous three- or four-coloured illustrations, mention may be made of those opposite p. 8, entitled "Still Life," by Messrs. John Swain and Son, Ltd., opposite p. 128, entitled "Dessert," by Messrs. H. Kollien and Co., and following p. 136, entitled "Mimosa Blossom," by Messrs. Hood and Co., Ltd.

Einführung in die mikroskopische Analyse der Drogenpulver. By Dr. L. Koch. Pp. viii+174. (Berlin: Gebrüder Borntraeger, 1906.) Price 4 marks.

THE microscopical examination of drugs for the purpose of gaining an accurate knowledge of their constitution and of learning to detect impurities and adulterations is now recognised as a necessary part of the usual courses for pharmaceutical students, and as many chemists endeavour to acquire part of their knowledge during the term of their apprenticeship, they require books of this nature to help them in their independent studies.

Dr. Koch has prepared this elementary manual as an introduction to the specialised vegetable histology that affords the principal means of distinguishing pharmaceutical products with the aid of the microscope. A few examples of well-known drugs selected as specimens of bark, seed, and other plant products are described in detail, and the elements are figured. The instructions are so minute and thorough that a student using the book intelligently should soon become proficient in histological determination. The chapter on methods is not, however, so complete as would be expected. Although powdered preparations are generally used for investigations, it is at least desirable that the student in his training should become efficient in section cutting. Further, a more extensive account of reagents would be helpful, for while agreeing with the substitution of chloral hydrate in place of potash, there seems no reason for leaving out potash altogether, or sulphuric acid and several other recognised testing solutions.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

An Occurrence of Helium in the Absence of Radio-activity.

I MENTIONED in NATURE a few weeks ago (January 17, p. 271) that I was engaged in examining the inert gases contained in ordinary (inactive) minerals. A result has been obtained so surprising that it seems worthy of immediate record. I have found that beryl contains a quantity of helium of quite a different order of magnitude from what is found in ordinary inactive minerals. Thus 250 grams of beryl from New Hampshire gave 4·2 c.c. of helium on heating. The mineral appears to be absolutely without radio-activity. A tray of the powder, placed in the case of an electroscope of exceptionally small natural leak, did not increase that leak to any measurable extent.

It seems likely that we have here a case of rayless change. In all probability beryllium is the constituent of beryl which is concerned. It is hoped to test this view further by the comparison of different minerals.

Sunnyside, Cambridge, February 19.

The Rusting of Iron.

SEVERAL letters have appeared in NATURE respecting the conditions under which iron rusts. The usually accepted view has been that iron will not rust unless carbonic acid is present. After a very careful investigation of the subject I was led to the conclusion that provided iron, oxygen, and liquid water are brought together, chemical change takes place with the production of rust even when every precaution has been taken to exclude even traces of carbonic acid, and that therefore some other explanation must be found for the fact that alkalis inhibit the rusting of iron. An explanation has also to be found for the fact, established in the course of this investigation, that if polished iron is immersed in a solution of potassium dichromate rusting is completely inhibited, and the surface of the metal remains perfectly bright (Dunstan, Jowett, and Goulding, Journ. Chem. Soc., 1905).

Dr. Gerald T. Moody has recently given (Journ. Chem. Soc., 1906) an account of experiments he has made from which he concludes that carbonic acid is essential to the rusting of iron, and that rusting does not occur in its absence.

As these experiments were made under somewhat different conditions from mine, they have been repeated. The results obtained are, however, not confirmatory of the conclusion that carbonic acid is essential to the rusting of iron.

This apparently simple chemical change requires additional experimental study, and I hope shortly to be able to make some further contribution to the subject.

Ionisation and Anomalous Dispersion.

THE experiment recently described in a letter in NATURE by Dr. Schott (January 17, p. 271) does not appear to me to have any very direct bearing upon ionisation. There appears to be no question but that the changes observed in the dispersion curve were due to an alteration in the optical density gradient of the sodium vapour, resulting from local heating by the wire. The experiment is very similar to one which I made two years or more ago, during an examination of the physical properties of the vapour. A wire was stretched through the tube, along its axis, and heated by a current. The vapour was observed to be much less dense around the heated wire. The observations were made by looking through the tube either at a sodium flame or a lamp behind bluish-green glass (for which light the vapour was very opaque). On heating the wire a clear space appeared around it. If I remember rightly, I never published this result, as the experiment was one of a series which has not, even yet, been completed.

In a sodium dispersion tube the density of the vapour

is very great along the floor, immediately above the surface of the molten metal, falling off very rapidly as the roof of the tube is approached It has always appeared to me probable that we are dealing with clusters of molecules, though there may be some simpler way of explaining the very steep density gradient At all events, local heating of the denser portion of the vapour reduces its density, it seems to me, to a much greater degree than would be the case with an ordinary gas The steep density gradient only occurs when the top of the horizontal tube is cooler than the floor, that is, cool enough to condense the vapour The tubes I usually exhaust to a pressure of a millimetre or two, and I have always found it difficult to explain how it is possible to have a layer of vapour along the floor so dense that it is deep violet in colour, while along the roof the vapour shows no trace of colour at all On the kinetic theory, it seems to me that we should expect the vapour to be moving rapidly from the floor to the roof, without, however, showing much difference in density at different points It may be however, that the traces of hydrogen which are present may be the cause of the phenomenon What we call "very dense sodium vapour" along the floor of the tube may be pure sodium vapour at a pressure of only a couple of millimetres Along the roof we may have nearly pure hydrogen at the same pressure, and at intermediate points mixtures of the two in varying proportion, the sodium working its way up through the hydrogen and condensing on the roof It will be well to try a very highly exhausted tube

Upon the whole, I think perhaps this is the most conservative way of looking at the thing, though my impression is that the hot wire produces a greater reduction of density than we should expect on this assumption

Baltimore, February 5 R W WOOD

A New Chemical Test for Strength in Wheat Flour

THAT different wheats make flours of very different baking values has been known for a long time, and is emphasised by the fact that English millers are at the present time paying several shillings per quarter more for certain foreign wheats than for home grown wheat

Baking value, or strength as the millers and bakers call it, is a subject of much interest, and many workers have tried to connect it with some definite physical or chemical property of the grain or flour Thus it has been stated to depend on the percentage of gluten, the percentage of gliadin or the ratio of gliadin to gluten

None of these explanations has been found to meet all cases, nor is there any likelihood of finding any single factor which is capable of measuring so composite an idea as strength as understood by the miller or baker

The value of a flour to the baker depends on at least four distinct properties —(1) the volume of the loaf a given quantity will produce, which may vary more than 30 per cent, (2) the amount of water which a given quantity will absorb in making a dough of proper consistency for baking, which may vary from one-half to three-quarters of its own weight (3) the shape of the loaf, and (4) such points as texture and colour of the bread

The baker, and apparently most of those who have attacked the problem, have confused these widely divergent properties under the single name of strength, and attempted to find one chemical or physical factor which will measure them all at once

In taking up this subject it seemed to me that the most hopeful line was to treat each property as a separate problem, and as the question of size of loaf seemed simplest, I have for the most part confined my attention to that aspect of the investigation

In converting a given amount of flour into a loaf of bread, the flour is mixed with water and yeast, and allowed to ferment for some time It is then put into the oven and baked The yeast finds sugar in the flour, feeds on this, and converts it into alcohol and carbon dioxide, and the volume of the loaf must depend either on the volume of carbon dioxide evolved, or on the power of the flour to hold this gas

To test this a number of flours were obtained from Mr A E Humphries chairman of the Millers' Association, who had kindly tested them in the bakehouse, and determined their strength The scale of strength adopted is a purely arbitrary one The mark 100 is assigned to the best flour on the market and 0 to a flour which is quite unbakeable

In each experiment 20 grams of flour were mixed with 20 c c of water and half a gram of standard yeast incubated at 35° C, and the carbon dioxide liberated directly measured The results are appended —

Reference No	Baking value or strength	CO_2 evolved cc
1	96	270
2	90	325
3	73	274
4	68	227
5	65	205
6	45	156
7	36	131
8	20	287

It will be seen that with the exception of Nos 1 and 8 the order of strength and of carbon dioxide evolved are the same Perhaps the greatest confirmation of the idea that strength is directly dependent upon the capacity of a flour for acting as yeast food is found in the apparent exceptions On inquiry from Mr Humphries, I learned that the high mark assigned to flour No 1 was based upon bakings made after the addition of malt extract, while the low value given to No 8 was based on baking tests made some months earlier The high carbon dioxide value actually found for the latter enabled me to predict that the flour must have changed in composition so as to have gained in strength and this prediction was verified On baking again it was marked 40 with the report that it made a large loaf and would have been marked higher but for the bad shape

The quantity of carbon dioxide given off by a dough will depend upon two things—the sugar present is such in the flour, and the diastatic capacity Analysis showed that in the flours experimented with the sugar present varied from 2 56 per cent in the strongest to 1 60 per cent in the weakest, and followed very closely the order of strength throughout the series Diastatic capacity has not yet been thoroughly examined

The addition of sugar to flour was found always to increase the volume, the weight, and the height of the loaf In a typical experiment made with household flour the increases were as follows volume, 15 per cent weight 2 per cent, and height 30 per cent

These experiments seem to prove conclusively that the volume of the loaf depends in the first instance upon the amount of sugar available in the dough, and a ready test is thus provided for that aspect of strength which is concerned with the size of the loaf The other factors included in strength are at present under investigation

The Flight of an Elongated Shot

WITHIN the limits of accuracy of this discussion it may be assumed that the sections of the shot normal to its axis of figure are circular, that its C G is in the axis of figure, and that this axis and all the diameters of the circular section at the C G give the directions of the principal axes of inertia at the C G Angular momenta will be referred to the C G, the axis of the shot will be called simply the axis and all directions will be understood as viewed from behind the shot

The chief disturbing forces are the normal pressures of the air the frictional forces being of a secondary order of magnitude These normal pressures will be at a maximum upon the ogival head of the shot The areas of such relatively smaller pressures as are due to vortex motion in the air, and to the partial vacua set up behind advancing surfaces directly presented to and against the air will be situated towards the base of the shot, and upon the upper or the lower side of the shot according as the axis is pointed above or below the tangent to the path of the C G, i e the tangent to the trajectory

Now, from the first moment of the free motion the tangent to the trajectory falls away more and more from the axis of the shot The immediate result of this is the

setting up of an area of maximum pressure upon the underside of the ogival head This gives rise to a resultant disturbing couple, which, by reason of the symmetry of the surface, has its axis parallel to the horizontal principal axis at the C G, and this axis is directed rightwards Since this disturbing couple has its axis at right angles to the axis of angular momentum, i e to the axis of figure, it causes a precessional motion of the axis in the plane of its own axis and of the axis of figure, so that this axis begins to turn itself slightly to the right of the trajectory, the rifling being taken to be right-handed This action is a very small one, because the couple producing it is very small compared with the couple which is equivalent to the total angular momentum The axes of angular momentum and of angular velocity being initially coincident with the axis of figure, while the axis of the disturbing couple is at right angles to it and parallel to one of the principal axes at the C G, this couple has no effect upon the magnitude of either the angular momentum or the rotational velocity It alters only the orientation of the axis of angular momentum and leaves it coincident with the axis of figure

Now this deflection of the axis to the right causes the left side of the head of the shot to experience a greater normal pressure than the right, and so gives rise to a second disturbing couple of small magnitude relatively to the whole angular momentum, about an axis parallel to a principal axis at the C G and directed downwards very nearly if not exactly, in the vertical plane through the axis of the shot The effect of this is to bring about a precessional motion of the axis in this plane directed downwards, so that the nose of the shot begins to dip towards the tangent to the trajectory This couple has, otherwise exactly the same effects on the motion of the axis as the other one and since both couples are very small in comparison with the total angular momentum it is permissible to combine their effects after considering them separately It thus appears that the axis acquires a small precessional motion about the tangent to the trajectory, and that the excess of pressure upon the left of the head will cause the trajectory itself to be bent to the right bringing about the well-known rightward drift of the shot If the rifling be left-handed the shot will drift to the left, but the nose of the shot will, as before, dip towards the trajectory

Any device that throws the C G well towards the base of the shot will have the effect of adding to the magnitude of the first of the above two couples A smaller deviation of the axis from the trajectory will then afford a larger disturbing couple and the rightward precessional motion will be more quickly established In consequence of this the rightward drift will be diminished A long, hollow bullet of thin steel, the rear half having a smaller diameter than the front half and this rear half being filled with lead, and also coated exteriorly with lead so as to take the rifling, may, on this theory, be expected to have less drift than the ordinary bullet, whereas a bullet weighted towards the head would have more

The Problem of the Random Path

THE following illustration of Prof Karl Pearson's "Random Path" problem may be of interest

Mr Kipling in his story "The Strange Ride of Morrowbie Jukes," gives the following directions for finding the safe path across a quicksand, which directions are supposed to have been found by the hero of the story in the coat of an earlier victim —

"Four out from crow-clump, three left, nine out, two right, three back two left, fourteen out two left, seven out, one left, nine back, two right six back, four right, seven back"

These numbers were probably taken at random, and it will be noted that seventy five paces are taken and the final position is only seven paces from the original position

This is a rather curious confirmation of Lord Rayleigh's solution of the problem

REGINALD A FESSENDEN

SPEECH CURVES[1]

DR SCRIPTURE since 1901 has worked with zeal and energy at experimental phonetics, and he has published several valuable papers, as well as a large volume treating generally of the subject. The work has been carried on with the aid of the Carnegie Institution of Washington at Yale, Munich, Berlin, and Zurich It has been an expensive research, as in addition to costly apparatus a staff of clerks was required for computation A perusal of this monograph proves that Dr Scripture has shown great ingenuity in the construction of recorders and in overcoming technical difficulties that can be fully appreciated only by those who have made excursions into this field of research His experimental method has been to transcribe on smoked paper the curves of speech both from the gramophone of Berliner and the phonograph of Edison

On the disc of the gramophone the curves produced by sound vibrations are not indentations in the bottom of a groove or furrow, as in the tracing on a phonograph cylinder, but they are horizontal, as if they were drawn on the plane of a sheet of paper Further, it is interesting to note that in the gramophone record the depth of the groove is constant, whereas in that of the phonograph the downward movement of the recording disc bearing the cutting tool is diminished, in consequence of increasing resistance, in comparison with the upward movement Each instrument has its own peculiar quality of tone and, except in very fine modern instruments, natural sounds are more or less falsified This falsification Dr Scripture shows is due to a distortion of the waves by the bending of the diaphragm, and not to nodal vibrations such as occur on Chladni's plates His best tracings were taken from gramophone records by using either a simple or a compound lever, which at one end travelled slowly over the record, and at the other recorded the waves on a moving strip of smoked paper

There is no special novelty in this method except that it has been applied to the gramophone, and that the mechanical arrangements have been of the finest quality It gives one a notion of the delicacy of the method when it is stated that 1 mm of the tracing = 0 0004 sec The vertical magnification by the use of a simple lever was 300 times, but Dr Scripture adds —"The future of the method lies in the development of a compound lever" Great care was taken to identify any portion of the record on the smoked paper with the corresponding part of the surface of the gramophone plate This was accomplished by a very ingenious device The reproduction of the curves for printing was done by etching on zinc An example of a tracing of the sounds of an orchestra is shown in Fig 1, and the following is Dr Scripture's description —

"The curve in Fig 32 [Fig 1] is from the record of a note from an orchestra The most prominent vibration is one whose wave-length is 3 mm = 0 0012 sec, that is, about the note $g^2\sharp$ Another prominent feature is the grouping of these vibrations in threes, indicating a tone with a period of 9 mm = 0 0036 sec, or a note about $d^1\sharp$. There is one which reinforces every sixth vibration of the high note and another that coincides approximately with every ninth, the former would correspond to $c^0\sharp$, the latter to $g^{-2}\sharp$ The combination of all these notes—each comprising a fundamental with overtones—produces a very complicated curve From such vibrations, however, the ear can pick out not only the component notes, but also the characteristic tones of the piano, violin, &c" (p 33)

1 "Researches in Experimental Phonetics the Study of Speech Curves By Dr E W Scripture Pp 204 (Washington, D C Published by the Carnegie Institute of Washington, 1906)

In a similar manner Dr. Scripture gives a careful description of a large number of tracings of noises, whistling, various musical instruments, and human speech.

We now approach the most difficult part of the investigation, namely, the analysis of the curves produced by human speech. Dr. Scripture's plan has been to analyse carefully portions of actual speeches,

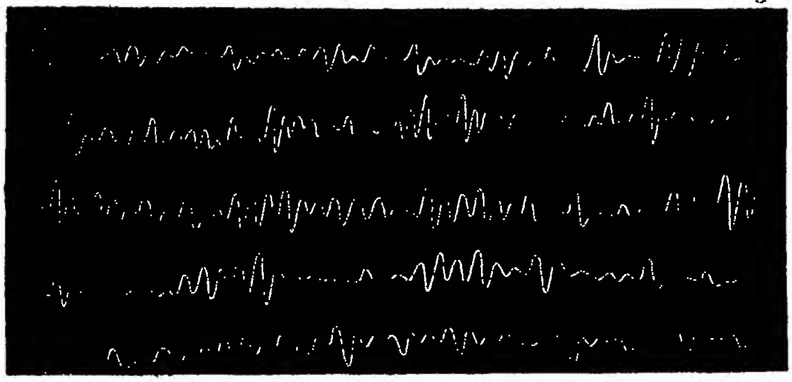

FIG. 1.—Record of a note from an orchestra.

as, for example, that of Chauncey M. Depew on "Forefather's day," when he says "Without regard to race or creed I can" &c., or from "Cock Robin," "With my little eye I saw him die" &c., or Joseph Jefferson's speech in proposing Rip Van Winkle's toast, "Come, Rip, what do you say to a glass? That's fine schnapps." As an example, take a small portion of the latter speech:—

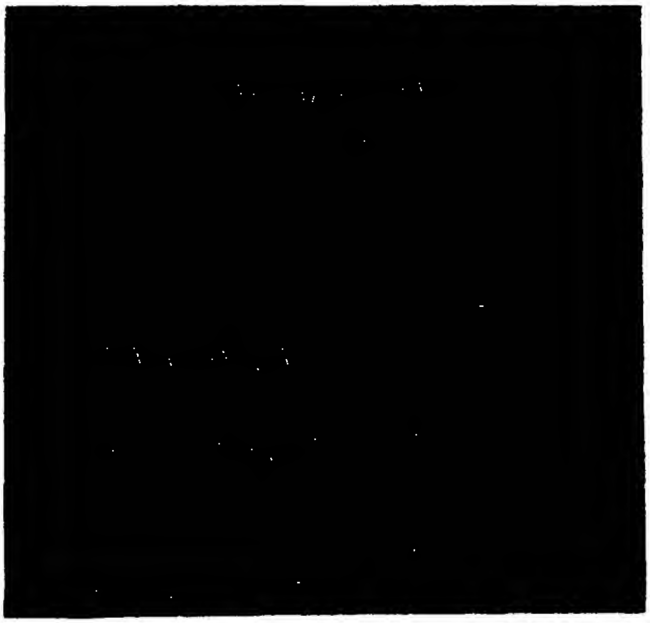

FIG. 2.—Curves showing waves from various vowels spoken by Joseph Jefferson in "Rip Van Winkle's Toast."

Each line contains only a few waves out of the curve for a vowel, and Dr. Scripture gives a careful analysis. It would have been better, I think, if Dr. Scripture, with his fine appliances, had given us an exhaustive examination of each vowel, not as it occurs in such a speech as we are considering, but by itself. The vowels here examined are "American vowels." Would it not have been better to have obtained first-rate gramophone records of clearly sounded vowels, and then to have reproduced the curves of these sounds? However, there can be no doubt Dr. Scripture's analysis teaches us a great deal. One would have expected that the wave forms in a vowel tone would have had the same form or shape for a short time, but it would appear that this is not so.

"So much has been said," writes Dr. Scripture, "of the complexity and the variability of the speech curves that the impression may have been produced that they are hopelessly irregular. This is not true. They are as irregular as the leaves of a tree; no two are alike, yet the individuals of a variety resemble one another, and differ from other varieties" (p. 49).

"As already pointed out, no two waves of a vowel are alike; the differences are often so great that we may be sure that one part sounds utterly different from another although the ear apparently gets only a single general impression" (p. 53).

Dr. Scripture then devised a method "whereby the ear can be enabled to hear the sound of each wave separately." A special apparatus was constructed by which a single selected wave was many times repeated on a strip of zinc, then etched, and then transferred to the gramophone disc. The group of waves reproduced the sound represented by these exactly similar waves, and the ear was appealed to as to the resemblance of the sound to any particular vowel. This is quite a novel method of investigation, and suggests further experimental work. It shows the possibility of transferring any set of curves to a gramophone plate and then listening to the sound and comparing it with other sounds. The writer of this notice, by another method, has obtained many curves of vowels, and he cannot altogether bear out the statement of Dr. Scripture that all the waves differ from each other. At the beginning of a vowel tone, and towards its close, the waves may differ, although of the same general type, but in the middle of the tracing, when the vowel tone is clear and distinct to the ear, the waves appear to be the same in form.

In the analysis of speech curves, Dr. Scripture attaches importance to what may be termed the melody of speech. We have "melody" when sounds of different pitch are heard after one another.

"The study of melody is the study of the fluctuations of the pitch of the tone from the glottal lips. Each explosion puff, or vibration from the glottis arouses a vibrating movement that shows itself in the speech curve as a group of vibrations; this we have called a 'wave group' or a 'wave.' A 'wave' thus means the whole complicated group of vibrations resulting from a single glottal movement. The study of melody has to do with these waves or wave-groups."

By a special method Dr Scripture plots a melody curve from a transcribed record, showing, for example, the curve when "Oh" is uttered "sorrowfully" or "admiringly," or "questioningly," &c He works out the "melody curves" in Depew's speech, and then writes the melody in musical notation With regard to the emphasis of speech as indicating the emotional condition of the speaker's mind, we must, however, take into account not only melody, or the sequence of tones of different pitch, but also the intensity, the passing from *diminuendo* to *crescendo*, or *vice versa* Dr Scripture has not attributed sufficient importance to this element in the analysis The amplitudes of the wave forms increase or diminish according to the intensity

Dr Scripture expounds the principles of harmonic and inharmonic analysis in two chapters at great length and with much clearness Nowhere have I met with a fuller exposition of Fourier's theorem and its application to acoustical problems He does not hold, however, that a vowel curve is produced by combining simple sinusoid vibrations in a harmonic series, and he concludes that

"the sounds from the musical instruments are presumably produced in this way but we dare not assume that the vowels are so produced until the fact has been proven" (p 78)

He shows how to separate, by the rules of Hermann harmonic and inharmonic sinusoids from the mixed results of a harmonic analysis How is one vowel distinguished from another? Are the differences due to the presence of certain tones of definite pitch, as held by both Helmholtz and Hermann? If so are we to hold with Helmholtz that these tones are harmonic overtones of the glottal tone or that they are inharmonic to it, as stated by Hermann? Dr Scripture holds that Hermann has completely disproved the theory of Helmholtz After discussing the method of analysis with frictional sinusoids, as distinguished from simple sinusoids, he states —

"The vibrations of the voice in speech are composed exclusively of frictional sinusoids and not of simple sinusoids, as has hitherto been assumed Can a method of analysis into frictional sinusoids be found? Does an analysis into simple sinusoids give false results for the vowel curves?" (p 101)

He answers the question thus

"The treatment of the curves by simple harmonic analysis the only method that has hitherto been tried—furnishes results that are so wrong as to be utterly misleading when used to indicate the manner in which the vibrations were produced"

I observe that Dr Scripture states that Prof Weber of the Swiss Polytechnicum, along with Schneebeli was the first to apply the Fourierian analysis to a vowel curve, but he does not give the date when this was done We must not forget that such an analysis was made by Fleeming Jenkin and Ewing in 1878 ("On the Harmonic Analysis of certain Vowel Sounds" *Trans Roy Soc Edin* vol xxviii p 745)

As to the mode of production of vowel tones, Dr Scripture discards the views of Wheatstone, Grassmann, and Helmholtz that the glottal lips vibrate after the manner of strings or the borders of a membrane on each side of a narrow opening, and he fully adopts the "puff" theory of Willis and Hermann, according to which

"the glottis emits a series of more or less sharp puffs, each puff, striking a vocal cavity, produces a vibration whose period is that of the cavity, a single wave group shows the sum of these vibrations from all the cavities, the periods of these vibrations may stand in any relation to the interval at which the puffs come, that is to the fundamental"

There can be little doubt that, at all events in his later days, Helmholtz saw the analogy between the action of the glottis and the "puffing" sounds of a syren, but he undoubtedly held that the overtones were harmonics of the glottal tone Hermann, however, has conclusively shown that at least some of the tones of the cavities may be inharmonic to the glottal tone, and Dr Scripture supports this view by many ingenious experiments His description, however, of the glottis is not either anatomically or physiologically quite satisfactory It is not in accordance with anatomical detail to write, "Each glottal lip consists mainly of a mass of muscle supported at the ends and along the lateral side," or that "the two masses of muscle close the air passage," or that the air from the trachea "bursts the muscles apart" The glottis is a much more delicate structure than these words would imply It contains much elastic tissue at the borders which come together, according to the "puff" theory, and the muscular structures are devoted to placing strains on this tissue and to separating or approximating the lips of the glottis Dr Scripture's view is that

"the effect of each puff on each element of the vocal cavity is double first to arouse in it a vibration of a period depending on the cavity, second, to force on it a vibration of the same period as that of the set of puffs"

The glottal puff produces a frictional sinusoid with large amplitude and a very large coefficient of friction, and the cavity vibrations are also of the frictional sinusoid form This may explain the failure of a simple harmonic analysis to reveal the real elements of the vowel curve

In chapter ix Dr Scripture gives his views as to the action of the organ of Corti in relation to wave analysis, and he conjectures that portions of it are affected by "groups of stimuli," when complex wave forms reach it This does not seem very conclusive, and in my judgment the theory of Helmholtz, by which he explained the action of the organ by adopting the principle of resonance, still holds the field

Dr Scripture has also attempted a synthesis of vibrations by ingenious mechanisms, by which he obtained curves somewhat similar to speech curves There is no doubt a great future for this line of experimental research After fully worked out examples of vowel analysis, with all arithmetical details, Dr Scripture appends to the end of the monograph a number of elaborate schedules to assist in the Fourierian analysis, namely, schedules of 12 ordinates, 24 ordinates, 36 ordinates, and 72 ordinates The preparation of these schedules was a very laborious task, and the work will be much appreciated

We congratulate Dr Scripture on the production of a splendid monograph It might have been improved by fuller bibliographical details, and perhaps by a more adequate recognition of the work of others

JOHN G MCKENDRICK

AGRICULTURAL EDUCATION AND RESEARCH [1]

ONE of the functions of the Board of Agriculture is the administration of a Treasury grant for the purposes of agricultural education, and though the total distributed is not large it has been a potent factor in stimulating the development of the higher forms of agricultural education during the last fifteen years It is certain that many of the county councils

[1] The Annual Report of the Board of Agriculture and Fisheries on the Distribution of Grants for Agricultural Education and Research in the Year 1905-6

which now help to maintain colleges giving instruction of a university standard would have never started at all or would have rested content with something in the nature of a farm school had it not been for the advice and practical encouragement provided by the Board of Agriculture.

During the past year we see that seven institutions were in receipt of an annual grant of 1000*l*., 200*l*. of which was in respect of the farm maintained by the college, while twelve other institutions received sums ranging from 800*l*. down to 100*l*. The University College of North Wales at Bangor and the Armstrong College at Newcastle each received a further 250*l*. for instruction in forestry. It is noticeable that the Board seems to make the amount of its grant depend upon the type of education given, not taking into account the number of the students educated or the extent of local support. Thus Wye College, the total expenditure of which is set at 17,414*l*., receives the same grant, 1000*l*., as other colleges the total expenditure of which does not reach 3000*l*. Probably this policy is most adapted to the pioneer work, when it is all important to get the colleges started, but the time is drawing near when some of the colleges supported most liberally by their localities must feel that they should be treated on the principle of the Treasury grants to university colleges, which are given roughly in proportion to the local support received.

In the body of the report nearly all the collegiate centres have the same tale to tell of an increase in the number of students, and that greater use is being made of the college by the farmers in the district. It is not too much to say that the attitude of the general body of farmers towards scientific work has entirely changed during the last ten or twelve years, wherever they have been within the range of influence of one of these permanent centres of instruction. The supply of agricultural intelligence certainly preceded the demand, but now the demand has more than grown up to the supply.

The second part of the present year's report deals with the expenditure of the various county councils on agricultural education of various kinds out of the funds they derive from the "whisky money." From this we learn that in 1905-6 the counties of England and Wales expended very nearly 84,000*l*., of which about 30,000*l*. went to colleges and schools, the remainder being spent on lectures or instruction in horticulture, bee keeping, poultry keeping, and various manual processes. Useful as no doubt much of this work is, popular as it is made to be by being spread thinly over a wide area and liberally endowed with prizes, it does little or nothing for the advancement of agriculture, though it may be doing something to make life easier for the cottager. The failure of agricultural instruction that is divorced from any permanent teaching centre may be read in the steady decline in the expenditure for such purposes of the counties which are not connected with any of the institutions subsidised by the Board. There are, indeed, several counties content to spend nothing on agriculture, though their only interests are agricultural, West Sussex, for example, spends not a penny, while several others get through on less than a hundred a year.

When one comes, however, to the second part of the title, "Grants for Agricultural Education and Research," this report makes an indifferent show, since the grants for research only total 355*l*.! Of course, some part of the grants to the colleges is available for research, but if we except the fine work that is being done at Cambridge, there is little going on at the colleges which could come under the category of research. The 355*l*. consists in the main of grants to various institutions carrying out a particular experiment on the improvement of poor pastures, and one sum of 50*l*. to the committee which is working at the improvement of English wheat. Rothamsted still remains without a grant.

Account should also be taken of one or two departmental committees which are inquiring into stock diseases; at present, for example, there is one at work on contagious abortion in cattle, and a former inquiry into "louping ill" in sheep has recently reported—the two costing about 3000*l*. But compare this expenditure on research with that of the United States Department of Agriculture; from the appropriations for the fiscal year ending June 30, 1905, we extract the following items for investigation work alone, exclusive of the salaries of the permanent officials of the Department:—

	£
Botanical investigations and experiments	13,500
Entomological investigations	14,000
Vegetable pathological investigations	30 000
Biological investigations	6,800
Pomological investigations	8 700
Laboratory Department of Agriculture	27,000
Experimental gardens and grounds, Department of Agriculture	5,000
Soil investigations	34 000
Grass and forage plant investigations	8,500
Cotton boll investigations	50 000
Sugar investigations	1,500
Tea culture investigations	2 000
Total	201 000

It is the smallness of the Board's contribution to research, the life blood of scientific education, which led Mr. J. T. Mason, the Member for Windsor, to move an amendment to the address last week to direct attention to the neglect of agricultural research on the part of the Government. Mr. Mason dwelt upon the prime importance of research to farming in this country, where intensive farming is carried on and a large monetary return per acre must be obtained. He instanced the losses that have been occasioned by plant diseases, which could only be dealt with after organised investigation of their causes and origin. He particularly pleaded for assistance to Rothamsted, the one institution for agricultural research of the first rank that this country possesses, but which, deriving its income from private benefactions only, is now handicapped for lack of funds.

The amendment received a sympathetic discussion from members on both sides of the house, and Sir Edward Strachey, for the Board of Agriculture, said "that no one was more anxious than he to see larger sums applied to experiment and research. But scientific investigation had suffered in the past not so much from neglect as from want of appreciation on the part of the public. If the House had omitted to provide sufficient funds for such investigation, it was because the question had not been brought forward. . . . On the other hand, it might very fairly be said that there was a general demand among agriculturists for larger grants from State funds, and the House might rest assured that the President of the Board of Agriculture would make representations to the Treasury as to the general feeling expressed in the debate on that point."

But now that the question is attracting public attention we trust that the Board of Agriculture will be encouraged to make bolder demands on the Treasury. There was a scheme for creating a council for agricultural research which seems to have fallen

through for lack of an initial grant, there are also the recommendations of the Royal Commission on fruit-growing, which seem no nearer realisation, as an advisory body the Board of Agriculture must get itself discredited unless it possesses some machinery for investigation.

THE UNIVERSITY OF TORONTO

THE very generous provision recently made by the province of Ontario for the financial support of the University of Toronto, as well as the very important changes brought about last year in the constitution of the latter, are of more than local interest, and therefore the following account may be of service to those who watch the development of the colonial universities.

This university, which was founded by Royal Charter in 1827 and began teaching in 1843, had as its original endowment 225,000 acres of Crown lands in the province of Upper Canada, now Ontario, and the amount realised from the sale of these lands gave, with the tuition fees, all the revenue the university had until 1897, when the Legislature granted it 1400*l.* a year and 132,000 acres of wild lands within the unsettled portions of the province. In 1901 the Legislature further undertook to pay the annual charge of the departments of physics, chemistry, and mineralogy and geology. This latter addition to the resources of the university was rendered necessary by the gradual decrease in the revenue from the endowment and by the great increase in the number of students in attendance, taxing the energies of the teaching staff and the accommodation of the class-rooms and laboratories to the utmost. Until 1906 the revenues were spent in supporting two faculties, arts and medicine, as the annual budget of the School of Practical Science (engineering and technical science generally) was met directly out of the provincial treasury.

This provision of 1901 met the situation for about three years, but in 1905 the need of additional laboratories and other buildings, as well as the continually increasing numbers of students, made the question of further financial aid a very pressing one. There was also the question of the advisability of changing the relations which hitherto existed between the State and the university. All appointments to the staff had been made by the Lieutenant Governor in Council, and though these had been free from political taint, there was the possibility of such being dictated by considerations of party politics. It was also recognised that the constitution of the university was very cumbrous and unadapted for the work it had to do.

The urgent aspect of the situation led the newly installed Whitney Administration to appoint a Royal Commission to examine and report upon the constitution of the university and its constituent colleges and faculties. The commission was a very representative one, and from the first it earnestly set about its task, which was recognised to be a difficult one. It visited the larger American universities, conferred with their presidents and others who could furnish any aid in the form of advice, and patiently heard the views of the staffs of the various colleges and faculties. This commission also took up the financial problem of the maintenance of the university.

The results of their labours were presented in the form of a report to the Lieutenant-Governor of the province in March of last year, and at the same time the commission drafted a bill for introduction into the Legislature to embody, in the form of an Act, the changes which were thought advisable in the constitution. The suggested changes practically involved re-casting the constitution. The Act was accepted by both sides of the Legislature, and only minor modifications were made in its passage through the House.

Some of the changes made were sweeping. The control of the university was vested in a board of governors, twenty in number, eighteen appointed by the Crown, one the chancellor, elected by the graduates, and one the president, appointed by the board. This board was given the management of the endowment and income, but it can make no appointment to the teaching staff except on the recommendation of the president, on whom now devolves the responsibility for the staff of the university. By the Act the School of Practical Science was made an integral part of the university, and its finances were made subject to the control of the board of governors.

By far the most important result of the Royal Commission's labours, and which was embodied in the Act of the Legislature, ensures to the university henceforth adequate financial support. The provision to this end consisted in the granting to the university each year one-half of the annual average amount of the revenues derived by the province from succession duties or death duties, the annual average to be based on the receipts of the preceding three years. The total amount of these duties for the years 1903-4-5 was 304,800*l.*, or annually 101,600*l.* One-half of this latter sum has, as the Act directs, been paid to the university for the academic year 1906-7. As the province is growing wealthy rapidly, and consequently these succession duties are annually increasing in amount, of course the sum to be handed over annually by the province to the university will correspondingly increase. The amount to be thus given for the academic year 1907-8 will be 71,000*l.*, and it is estimated that the university will receive from this same source in 1908-9 about 100,000*l.* What it will be in a few years more cannot be approximately forecasted, but it is not unlikely that within ten years the death duties may average 300,000*l.*, of which the university would receive 150,000*l.*

As the ordinary income of the university, apart from that derived from succession duties, and apart also from interest on scholarship funds, is about 44,000*l.*, it may be seen that the total income from all sources for 1906-7 is 97,400*l.*, and for 1907-8 about 118,000*l.*, but for 1908-9 it will be about 147,000*l.* It is not at all improbable that the income of the university five years from now may be in the neighbourhood of $1,000,000, or more than 200,000*l.*

This is a very large income, but it must be noted that the work that the university has to do is also very great. It has not to undertake instruction in agriculture, for the province already maintains a splendid College of Agriculture at Guelph, for which the annual budget is about 30,000*l.* It has, however, to provide adequately for faculties of arts, medicine, applied science, and education, and the task may be gauged from the fact that there are already 2700 students in the first three faculties. It has also to do for Canada what the great American universities are doing for the United States, that is, to meet the demand for advanced teaching and for research in all departments. It is, indeed, the ambition of some to develop the university into as great a representative of learning and research as either Harvard or Johns Hopkins is, and to make it at the same time a centre for the intellectual life of the Canadian nation to be. As it is now, it is the largest and wealthiest colonial university of the Empire.

A. B. MACALLUM.

PROF J F W VON BEZOLD

It is with deep regret that we record the death on Sunday last, February 17, of Prof Wilhelm von Bezold, director of the Prussian Meteorological Institute

Von Bezold was born at Munich in June, 1837, and was admitted to the degree of Ph D at Gottingen in 1860 Thence he returned to Munich as privat-docent in 1861, became extraordinary professor in the University in 1866, and ordinary professor at the Polytechnic in 1868 In 1878 he undertook the organisation of the Bavarian meteorological service as director of the central meteorological station, and remained in charge of the service until 1885, when he was called to Berlin as professor of meteorology in the University, and director of the Meteorological Institute, which was reorganised by him

The Institute included not only the central establishment in Berlin, which formed the headquarters of the branch in charge of Prof Hellmann for dealing with the climatology and rainfall of the Prussian kingdom, but also the meteorological and magnetic observatories at Potsdam, in connection with which the names of Sprung, Eschenhagen, and A Schmidt are so well known, and the aeronautical section at Tegel, which was brought into existence and developed as a branch of the Institute under Prof Assmann A year and a half ago the work of the latter institution was transferred to the new and independent establishment at Lindenberg

In the course of his long and distinguished scientific career von Bezold's activity ranged over a wide field His writings include papers on colour vision and the retina, and the dust figures of electrical discharge, but he is best known for his contributions to meteorology as the physics of the atmosphere, the aspect of the subject which he found most attractive and to the theory of terrestrial magnetism A volume of his collected papers on these subjects was issued as recently as October, 1906, by Vieweg and Son It includes the papers on the thermodynamics of the atmosphere, contributed to the Berlin Academy which are the classical memoirs upon that section of meteorology The last paper in the collection contains his proposal for testing Gauss's theory of terrestrial magnetism by measurements along a complete parallel of latitude This was before the Association of Academies in London in 1904, when von Bezold was one of the representatives of the Berlin Academy

All who had the advantage of being associated with him in international work will miss his kindly presence and scientific enthusiasm, as well as his sympathetic and cautious counsel

PROF N A MENSCHUTKIN

PROF NICOLAI ALEXANDROVICH MENSCHUTKIN, who died on February 5, was born in St Petersburg on October 24, 1842 After finishing his studies at the St Petersburg University, he went abroad and worked in the laboratories of Schtreker in Tubingen, Wurtz in Paris, and Kolbe in Marburg On his return to St Petersburg in 1865, he read his dissertation for the degree of Master of Chemistry on "The Hydrogen of Phosphorous Acid and its Incapacity to be replaced by Metals" In 1867 he began to lecture on chemistry at the St Petersburg University He also gave special lectures on organic chemistry, and was head of the analytical laboratory. In 1885 he left the analytical department and devoted himself entirely to teaching organic chemistry His doctor's dissertation was on "The Synthesis and Properties of Hydrocarbons" In the seventies of last century he was secretary, and in the eighties rector, of the Physico-mathematical Faculty In recent years he left the University and lectured at the Polytechnic Institute of St, Petersburg

Menschutkin devoted his spare time to the Physico-chemical Society, the Journal of which he edited He was vice-president of the Students' Aid Society, and, being a fine musician, he organised the students' choir and orchestra

His first researches were on the inorganic acids, but he subsequently devoted himself almost exclusively to organic chemistry In the 'seventies he did some good work in the province of physical chemistry and in the mechanics of chemistry His researches on the influence of isomerism of alcohols and acids on the formation of composite ethers were published in the Records of the St Petersburg Imperial Academy in 1877, and he was awarded the Sokoloff medal for this work This was his first fundamental work, and it marked an epoch in the history of Russian chemistry Prof Menschutkin supplemented these researches by further work on the same subject in 1881 His researches on etherification from 1877 to 1882 brought many important additions to that branch of organic chemistry In 1898, 1900, and 1902 he was occupied in investigating the influence of carbon chains on the velocity of reaction and decomposition of carbon compounds. His last important research was on the velocity of chemical change in the polymethylene series, which was translated into English and published in the Journal of the Chemical Society A paper on the "Influence of Catalysts on the Formation of Anilides" almost closes his scientific career

His "Lectures on Organic Chemistry" passed through many editions His "Analytical Chemistry" became the text-book for all the Russian universities and technical schools In his preface to the sixth edition, which has been translated into English and German, Prof Menschutkin claims that analytical chemistry should form the basis for the study of organic and physical chemistry Prof Menschutkin, unlike his contemporary Prof Mendeléeff was a wonderful manipulator in the laboratory, and this was partly the secret of the precision of his results Prof Mendeléeff had the wider vision of the science, Prof Menschutkin excelled in details His earliest work was much influenced by his first teacher, Prof Sokoloff

NOTES

IT was announced in Sunday's *Observer* that the Government would shortly introduce a Bill dealing with the constitution of the proposed Imperial College of Applied Science at South Kensington and the relation of the college to the University of London We find, however, that this report is incorrect though the scheme for the establishment of the college was outlined nearly four years ago when Messrs Wernher Beit and Co offered 100,000*l* towards the cost and the London County Council agreed to contribute 20,000*l* a year for maintenance the matter is still in abeyance This delay as we have remarked before is both unfortunate and dangerous The chief point at issue is whether the college shall form part of the University of London and be controlled by the Senate of the University or whether it shall be an independent institution having a governing body of its own While the relationship between the two institutions is being decided there is no visible sign that the scheme is taking definite shape, and many men of science and leaders of industry are becoming impatient at the delay The departmental committee on the Royal College of Science

and Royal School of Mines in referring to the composition and functions of the governing body of the new college remarked (see NATURE, February 8 1906 p 345) —"Of the relation of the new institution to the University of London it is necessary to premise that we are agreed that it is desirable that the new institution should be established immediately, and that its organisation should proceed without delay" With this recommendation we are in complete agreement When the college has been in existence for several years it will be time enough to decide what its connection with the University must be In the meantime, the special governing body proposed by the departmental committee ought to be appointed to start the institution If something is not done soon the enthusiasm with which the scheme for the establishment of the new college for advanced instruction and research in applied science was received will give place to public condemnation of the dilatory methods adopted in a matter of great national importance

PROF A LIPPMANN and Prof Simon Newcomb have been elected honorary fellows of the Physical Society

DR C D WALCOTT director of the U S Geological Survey has been elected secretary of the Smithsonian Institution in succession to the late Prof S P Langley

PROF J MILNE F R S, will deliver the opening lecture of the session at the West India Committee Rooms this evening February 21 the subject being "The Construction of Buildings in Earthquake Countries"

A STORM area of more than usual magnitude was influencing the weather over the whole of the British Islands and indeed over the greater part of western Europe during Tuesday night and Wednesday The central area of the disturbance was situated near Skudesnaes at 8 a m on February 20, the barometer registering 27·65 inches, which is probably a record low reading in that position The barometer was below 29 inches over nearly the whole of the United Kingdom and the fall was unusually rapid Strong westerly gales occurred throughout Tuesday night and they were continuing yesterday in all parts of our islands as well as in France

THE executive of the British Fire Prevention Committee has appointed a special commission on concrete aggregations The scope of the commission is described in the following resolution —"That having regard to the confusion existing as to concrete aggregates, and the absence of their exact specification the British Fire Prevention Committee do hereby constitute from among its members and subscribers a special commission to report upon and define the aggregates suitable for concrete floors intended to be fire resisting having due regard to questions of strength expansion and the chemical constituents and changes of the aggregates" In forming the commission the various technical interests have as far as possible been represented Sir William Preece K C B, F R S will act as chairman, and Mr Matt Garbutt is honorary secretary Correspondence should be addressed to the assistant secretary 1 Waterloo Place S W

THE February number of the *Century Magazine* contains a short article on Amundsen's expedition and the North West Passage, by General A W Greely A short outline (illustrated by a map) of the history of the search for the North-West Passage is given and General Greely writes appreciatively of Amundsen's skill and daring in the handling of the *Gjoa*, as well as of the value of the magnetic work he carried out

THE *Times* of February 5 publishes a telegram from Calcutta stating that a message had been received there on the previous day from Dr Sven Hedin Dr Hedin reached Ngangon Tso on January 21, and hopes to arrive at Shigatse at the end of this month The explorer says that the journey approaching completion is the most wonderful he has made in Asia in twenty-two years Eight hundred and forty miles of unknown country, on a line running diagonally across Tibet, have been explored and mapped in 184 sheets Many new lakes, rivers mountain ranges, and goldfields have been discovered, and the geographical results are said to be extraordinarily rich

LIEUT BOYD ALEXANDER, who, along with his brother Captain Claud Alexander, Captain G B Gosling Mr P A Talbot (surveyor), and a Portuguese collector, left this country in the spring of 1904 on an exploring expedition across Africa has returned to London Captain Claud Alexander died at Maifoni in November 1904, and Captain Gosling in the Ubangi-Welle region in June 1906 Much valuable work has been accomplished A careful triangulation has been carried out from Ibi in Nigeria, to Lake Chad, and the lake itself traversed in various directions Part of the course of the Shari was explored, from thence the Ubangi was reached and the expedition made its way northward to the little known region where many of the Bahr el Ghazal tributaries rise and down the Yei to the Nile The expedition has been particularly successful in collecting specimens in natural history including skulls bones and skins of the okapi

DETAILED investigations of the Calabrian earthquake of September 8, 1905 are now appearing We have received a memoir by Prof Rizzo on the rate of propagation of this earthquake, and a note published in the *Atti* of the Turin Academy of Sciences in which he discusses the depth at which this earthquake originated, and adopts 50 kilometres as the most probable value Another paper by Dr Mario Baratta, in the Journal of the Tuscan Academy of Natural Sciences deals with the distribution of the damage and shows that there were seven distinct centres of destructive violence, and that the earthquake was a true polycentral one Indirectly this paper shows that Prof Rizzo's estimate of the depth of origin founded on the assumption that the focus was simple and comparatively restricted in extent must be in excess of the truth so that 50 kilometres should be regarded as the maximum possible, not the actual depth of origin

PROF P CARMODY, who was an eye witness of the earthquake at Kingston on January 18, has sent to the *Times* some details of the disturbance, from which we have obtained the following particulars of scientific interest — The building material that has best withstood the shock is wood and next to this cement Brick has suffered most and stone is almost as bad An examination of the several streets in different parts of the town shows that generally the east and west walls of the buildings have collapsed, while those facing north and south have been but little injured This indicates that the earth movement ran east and west Another striking general feature is that the east and west walls have fallen away from the rest of the building, meeting together in narrow streets, of which there are many running north and south, and therefore making it impossible for anyone to escape uninjured from these narrow streets The streets running east and west have not been completely blocked by fallen débris partly because they are wider, but principally

because the walls running in this direction have suffered less. A peculiar alteration in the position of statues in the square is deserving of record, as it may subsequently throw some light on the direction of the earth movement. On the south side of the square is a statue of the Queen. The figure is turned slightly to the left on the pedestal. In a corresponding position on the north side of the square another statue is turned slightly to the right. The statue of Père Dupont, facing north-east, was thrown off the pedestal and lay broken on the ground; another statue facing west is snapped across the middle, and the bust has dropped on the lower part of the pedestal, but not overturned. These four statues are within a hundred yards or so of each other. In Kingston the earthquake was revealed to most persons by a strong swaying, side to side motion, which soon changed to a sharp up and down shake and then terminated. The grating of the bricks and stones as they slid over each other was the first sound that distinguished it from the ordinary West Indian earthquake. Gusts of wind blew after sunset, and between 7 p.m. and 8 p.m. another shock was felt. During the night this was followed by six or seven others, and these were repeated during the subsequent day and night, but without causing further appreciable damage.

THE London County Council has decided to issue, under the superintendence of Dr. A. C. Haddon, a series of handbooks to the ethnological collection of the Horniman Museum, Forest Hill. The first of these, compiled by Dr. H. S. Harrison, has just made its appearance under the title of "From Stone to Steel," being a handbook of the cases illustrating the Stone, Bronze, and Iron ages. It is well illustrated, and describes clearly and concisely the various types of weapons and implements met with in the superficial deposits of Europe. The chief types of the human race met with in Europe are also noticed, while a general survey of the history of stone and metal implements in non-European countries is added.

HORSE-BREEDING in Wisconsin forms the subject of Bulletin No. 141 of the University of Wisconsin Agricultural Station, issued in November last, the report being drawn up by Mr. A. S. Alexander. New laws for the licensing of stallions for public service in Wisconsin came into force in January of last year, and the present report deals with the working of these laws, and at the same time suggests such further enactments as appear necessary to improve the breed of horses in the State. Special attention has been directed to the elimination of unsound horses, and with the present powers it has been found possible to enforce the retirement of a considerable number of stallions coming under this category. The ultimate aim of the authorities is, however, to get rid of all but pure-bred stallions for stud purposes; but, as elsewhere, farmers and breeders do not respond as heartily as might be desired to efforts which are essentially for their own benefit.

"THE Laws in Force against Injurious Insects and Foul Brood in the United States" is the title of the sixty-first bulletin issued by the Entomological Bureau of the U.S. Department of Agriculture, the text being drawn up by Dr. L. O. Howard, the entomologist and chief of the section, and Mr. A. F. Burgess, secretary of the American Association of Horticultural Inspectors. Bulletins covering much the same ground were issued respectively in 1895 and 1898, and the publication of the present issue has been rendered necessary by the enactment of new laws and the active interest in the subject recently manifested by several States in the Union. From the preface, it appears to have been found impossible to bring the work absolutely up to date, although practically all the more important laws are included. The issue also includes an account of the annual meetings of the American Association of Horticultural Inspectors from 1897 to 1905.

IN the course of an article on the biology of the sandy tracts of Illinois, by Messrs. C. A. Hart and H. A. Gleason, forming the seventh part of vol. vii. of the Bulletin of the Illinois State Laboratory of Natural History, the first-named author observes that sand-dwelling insects display a remarkable similarity in colour to their surroundings, this being essential owing to their exposed condition. The similarity is chiefly restricted to the dorsal surface, and is noticeable in insects of all orders. In the case of the Carolina grasshopper, individuals taken from the sandy tract appeared to be paler than those from the surrounding darker ground. The moulting of these insects takes place in daylight, when the colourless fresh exterior is exposed to the action of rays reflected from surrounding surfaces, and it has been suggested by Vosseler that these rays may by some kind of photographic action produce an approximation to the general colour of the environment. How the effect is produced remains to be explained, but the explanation seems a probable one.

ACCORDING to *Beilage zur allgemeinen Zeitung* for January 30, an expedition is in course of being organised under the auspices of the Royal Academy of Sciences of Berlin and the Government of the Dutch East Indies for the purpose of exploring Java in search of further remains of Pithecanthropus. The originator of the idea appears to be Frau Prof. Selenka, widow of the late Prof. Selenka, of Munich, who has already travelled extensively in Borneo for the purpose of collecting embryos of the orang-utan. Dr. Elbert is attached to the expedition as geologist, whilst Dr. Moszkowski, of Berlin, goes out as zoologist. A Dutch engineer, Mr. Oppenoorth, will have charge of the surveying and excavating operations. The Pleistocene volcanic breccia from which the original remains of Pithecanthropus were obtained by Prof. Dubois at Trinil is believed to have a wide extent in the mountains of Java, reaching in some places to a height of 100 metres or more above sea-level, and it is proposed to examine this stratum thoroughly in a number of the more promising localities. We may cordially endorse the hope expressed by our German contemporary that the expedition will succeed in its object, and bring to Europe a collection which will throw some definite light on the ancestry of the human race.

THE *Times* of February 4 contained an article on the grouse disease inquiry, summarising the results of the work of the departmental committee up to the present time. The committee, it will be remembered, was appointed by the Board of Agriculture, with the proviso that it was to find its own funds. It is for the most part composed of owners of grouse-moors, with Lord Lovat as chairman. From the point of view of progress in the inquiry, it is unfortunate that the work of investigation has coincided with a period of complete health among British grouse. The article criticises, not altogether favourably, a pamphlet issued by the committee under the title of "Notes on the Grouse," purporting to give a *résumé* of all that is known about the disease. Among its omissions is the absence of any reference to the theory that the midge may be the carrier of the infection. Whether

Klein's bacillus is really the cause of the disease must for the present be left open. Much time has been spent in searching for this organism, but hitherto without success. If the bacillus "should, after all, prove to have nothing to do with the disease, all this time will have been lost. It is not suggested that this will prove to be the case, but merely that it would have been better to start with an open mind on that point as well as upon others." It is pointed out that as no progress can be made while the disease is in abeyance, and that the original subscriptions to the committee were to last for three years only, further financial means will be required with the recrudescence of the malady in the future if any definite results are to be obtained.

THE Proceedings of the Cotteswold Naturalists' Field Club and the Transactions of the Hull Geological Society are excellent examples of the way in which the work of local societies may be produced. The former is printed by the historic house of John Bellows, in Gloucester. In the part for September, 1906, Mr. S. S. Buckman has a handsomely illustrated paper on Schlotheimia and species of other genera of Liassic ammonites. The reports of various excursions are accompanied by useful landscape-views. The Hull Geological Society, in its issue styled "vol. vi., part 1, for the years 1901–5," published in 1906, gives us Mr. Danford's detailed investigation of the belemnites of the Speeton Clay, with four remarkably fine plates of photographs, taken, like Mr. Buckman's, from the actual specimens. One is tempted to ask, however, whether the money spent so liberally on such papers would not have been better devoted to their production in the *Geological Magazine*. The excellent records of local surface-changes in Yorkshire, by Messrs. Butterfield and McTurk, and Mr. Richardson's note on Ceratodus from Westbury-on-Severn, stand, of course, in another category. The judgment of scientific readers must often be suspended between regret at the scattering of valuable work and admiration at the zeal with which it is put forward in its place of origin. It must be admitted that local publications of so high a standard are in themselves a stimulus to research.

THE Journal of the Royal Sanitary Institute for February (xxviii., No. 1) contains an important paper by Prof. S. Delépine on testing the germicidal power of various substances by the thread method, in which it is concluded that nearly all the problems of disinfection can be studied by means of it. Dr. Newsholme contributes a paper on the voluntary notification of phthisis in Brighton, and Dr. Heron one on coordination of measures against tuberculosis.

THE report from the Select Committee on the Housing of the Working Classes Acts Amendment Bill, which was recently issued, contains some important recommendations, particularly as regards sanitary administration. It is found that at present sanitary control is imperfect, and that the administration of the Acts by the rural district councils is neglected. Among the recommendations are transference of the administration of the public health and housing laws to the county councils, the provision of medical officers of health, properly qualified and adequately remunerated, so that they can devote their whole time and energies to the duties of their office, the provision of an expert staff of inspectors under the medical officer, whose title shall be altered from that of "Inspector of Nuisances" to "Sanitary Inspector", and the registration of every house and tenement in rural districts. It is considered that small local authorities cannot satisfactorily frame and administer building and public-health bye-laws, and it is suggested that the Local Government Board should establish a staff of officers for the special purpose of supervising the construction, sanitary condition, and repair of houses under the Public Health Acts, and the provision of houses under the Housing Acts.

No. 25 of the "Scientific Memoirs of the Government of India," by Captain S. R. Christophers, is devoted to a consideration of the importance of larval characters in the classification of mosquitoes. It is suggested therefrom that Stegomyia should be removed from the Culicina and placed in a group, *Stegomyina*, of its own; that Megarhinus and Toxorhynchites together with Mucidus and Psorophora (removed from the Culicina), should form a separate group, &c. Memoir No. 26, also by Captain Christophers, deals with the *Leucocytozoon canis*, a protozoan parasite of the white blood corpuscles of the dog, first described by Bentley and later by James. According to Christophers, *L. canis* comes within the division Hæmogregarina of Laveran, and very possibly represents the mammalian form of Karyolysus (Labbé). Reproduction occurs by the formation of true cysts containing about thirty sporozoits. Encystment takes place in cells of the bone marrow. After escaping from the cysts, the sporozoits invade mononuclear transitional cells in the marrow, where they are seen as naked, oval forms. These undergo changes and become encapsuled, whilst the host cell is altered in a characteristic way. The complete sexual development of this parasite takes place in the dog-tick (*R. sanguineus*).

THE *Kew Bulletin* was initiated in 1887, and although for a period the annual volumes were in abeyance, the series is now complete for a period of twenty years. The director of the gardens has recently issued an index as appendix v. to last year's volume detailing the contents from the commencement of the journal to the end of last year.

THE numbers of the *Agricultural News* (December 29, 1906, and January 12, 1907) lately received contain references to the agricultural conference at Jamaica that was so disastrously cut short. With regard to rubber in British Guiana, an expression of opinion by Dr. Bovallius is quoted wherein species of Sapium are recommended for cultivation on the lowlands in preference to Hevea and Castilloa, that require to be planted at a higher elevation.

SEVERAL references have appeared recently in the morning journals to an alleged cure for the opium habit emanating from the Straits Settlements. Mr. E. M. Holmes, writing to the *Times*, January 22, states that the plant has been identified as *Combretum Sundaicum*, a woody climber growing abundantly on the plains around Kuala Lumpur, in Selangor. Further information is supplied in the *Pharmaceutical Journal*, January 26, where Mr. Holmes says that it would be premature to express a definite opinion until a larger quantity of the material is available for chemical analysis and physiological investigation.

IT is probably unknown to many pteridologists that crested and other "sporting" ferns may not infrequently be collected in the British Isles. Mr. C. T. Druery, who has found several wild "sports," writing in the Journal of the Royal Horticultural Society (December, 1906), quotes as two instances the discovery of a markedly crested form of *Athyrium filix-foemina* at Kilrush, Ireland, and the

growth of a crested variety of bracken at Faygate, Sussex. Other papers in the same journal include an article on horticulture in relation to medicine and notes on tufted pansies, hollies, and the ideal potato. In the first named Mr. E. M. Holmes furnishes a list of plants now cultivated as herbs, among which one unexpectedly finds the nettle and mallow; an account of medicinal plants suitable for cultivation in this country is also given.

ACCORDING to the report of the Department of Agriculture in the Madras Presidency for 1905–6, a large experimental area has been acquired at the village of Taliparamba, in the Malabar district, for growing pepper vines with the object of studying their morphology, varieties, and other problems connected with their cultivation. Under the control of Mr. C. A. Barber, the results are likely to add materially to our knowledge of this historically and economically interesting product, and will, it is hoped, resuscitate the industry in South India. Other important products receiving attention are sugar-canes, ground-nuts, cotton, and tobacco, but experiments are not sufficiently advanced to furnish conclusions. The manufacture of door-mats, napkins, and muslins from the fibre of *Agave vivipara* is an extension of the usual applications of this fibre.

THE Cycads are so few in number, and they occupy such an important position in plant taxonomy, that a paper embodying new researches cannot fail to be interesting. As the outcome of an expedition to Chavarillo in the Mexican tropics, Prof. C. J. Chamberlain was able to secure material of the little-known ovule of the genus Dioon, and his results are published in the *Botanical Gazette* (November, 1906). The author obtained a series of stages from the appearance of the archegonium initial cell to the germination of the seed. The archegonia are formed in October to the number of four or five in each ovule; a neck cell is cut off, and subsequently a ventral canal nucleus separates mitotically from the egg nucleus. Haustoria are developed in connection with the transference of nourishment to the egg cell. The nucleus of the ovum is the largest known in plants, and contains twelve chromosomes. Incidentally, the author concurs with the opinion that plants of Dioon may continue to live for a thousand years.

A NEW journal bearing the title *Gaceto Matematika Internacia* is to be published in Esperanto. It will contain original articles on theoretical and applied mathematics, mechanics, and theoretical physics, reprints of articles published in other languages, reviews, correspondence, biographies, and papers on the history and teaching of mathematics. It is not intended to compete with, but rather to supplement and strengthen, existing journals. The publisher is F. J. Vaes, Mathenesserlaan 290, Rotterdam.

MR. B. M. DUGGAR details some experiments to ascertain the value of the osmotic pressures in the cells of certain marine algæ in a paper published as vol. xvi., No. 8, of the Transactions of the Academy of Sciences in St. Louis. Common salt, nitre, and sugar were used to make plasmolysing solutions, both in distilled and sea-water. It was found that the amount of nitre in sea-water required to plasmolyse together with the equivalent value of the salts in the sea-water was less than the amount in the fresh-water plasmolysing solution, while the reverse held good for sugar. An attempt to examine the toxic effects of adding to sea-water additional amounts of the different constituent salts occurring in sea-water elicited the facts that magnesium salts ordinarily toxic to phanerogams and fresh-water algæ were almost inert, and ammonium compounds were the most active.

FROM Messrs. Burroughs, Wellcome and Co. we have received a copy of the 1907 edition of their "Photographic Exposure Record," which is familiar to most of our photographic readers. It is bound in art green canvas, and is issued at a shilling. This neat pocket-book has been brought well up to date, and, as we have pointed out on previous occasions, should be the *vade mecum* of every photographer. Even in this small compass a great amount of useful information is compressed, in spite of increased space being provided this year for the record of negative exposures, there being room now for 336 entries. Each copy is accompanied by a folding card for hanging up, which gives useful information regarding the timing of development by the factorial method for various degrees of contrast, and particulars of equivalent plate speed numbers according to the different systems in use. An entirely new series of examples illustrates the article on exposure.

MR. JOHN C. PACKARD, of the High School, Brookline, Mass., sends us a description of an apparatus he has devised to determine the resultant of two motions at right angles to one another, one uniform, the other uniformly accelerated. A steel ball 1 inch in diameter, is placed at the top of an inclined plane of plate glass, and is made to acquire a uniform motion in a horizontal direction by being rolled down an auxiliary incline behind a ledge; the ball is then allowed to roll down the glass plane. A tracing of the curve generated by the ball is secured by fixing a sheet of squared paper to the plane and a piece of soft carbon paper over it. The ball in rolling over the carbon paper leaves its trace on the squared paper beneath. A study of the curve thus generated enables the pupil to arrive at the laws of uniformly accelerated motion.

A FOURTH edition of an "Introduction to Physical Chemistry" by Prof. James Walker, F.R.S., has been published by Messrs. Macmillan and Co., Ltd. The work has been enlarged by the inclusion of sections dealing with the behaviour of radio-active elements, atomic and molecular dimensions, and neutrality and salt-hydrolysis. Newer data afforded by recent researches have been substituted for the numerical values of previous editions.

WE regret that in a short notice of Prof. G. S. Boulger's work on "Familiar Trees" in NATURE of January 31, the reviewer was under a misapprehension when he remarked that certain trees had been omitted. The book reviewed is only the first volume of a new edition of Prof. Boulger's work, which is still being issued in fortnightly parts, and the missing species will be dealt with in another volume. The volume should, we consider, have been described as vol. i. on the title-page instead of using the words "First Series."

THE authorities of the British Museum (Natural History) have recently adapted the telephoto lens for securing accurate photographs of specimens. The installation consists of a 12×10 camera with an extension of 4 feet fitted with an 18×16 rectilinear lens and telephoto attachment, the whole apparatus being made by Messrs. J. H. Dallmeyer, Ltd. It has proved very successful, the improvement in perspective and depth of definition in the photographs being very noticeable when compared with those taken on the same scale with an ordinary lens.

OUR ASTRONOMICAL COLUMN

THE RECENT SOLAR ECLIPSE IN INDIA.—From a brief paragraph which appears in the *Pioneer Mail* for January 25 we learn that some interesting photographs of the partial eclipse of the sun were obtained at Dehra Dun (N.W. Prov. India) on January 14. A drop in the temperature of 4° corresponded with the passage of the shadow, and there was a very marked decrease in the illumination of the surrounding landscape. Venus became clearly visible to the naked eye.

THE LATE DR. ROBERTS'S CELESTIAL PHOTOGRAPHS.—A preliminary catalogue of Dr. Roberts's collection of photographs of various celestial objects and regions, comprising some 2485 original negatives, is published by Madame Dorothea Isaac Roberts in No. 4154 of the *Astronomische Nachrichten* (February 9). An introductory statement which accompanies it gives a brief account of the various classes of negatives, the period during which they were obtained, and the instruments employed by the observer. A complete list of Dr. Roberts's tribute to astronomy is to be published as soon as circumstances permit, and as the number of copies of the paper will be limited, those interested in photographic astronomy, and desirous of receiving a copy, are requested to send in their names at once to Madame Dorothea Isaac-Roberts, Château Rosa Bonheur, By-Thomery, S.-et-M., France. Positives on glass reproduced from the Isaac Roberts negatives will be lent for the purpose of micrometric measurements if application be made, and provided that the documents be returned after the completion of the measurements.

A LOST COMET (1905*f*).—Whilst examining three photographs taken at Mount Wilson on July 22, 1905, Prof. Barnard found the trail of a comet which appears to have evaded all other observations, and as the object might prove to be a periodic comet he now publishes some measures of position which he has made in order to determine, if possible, an approximate orbit, in No. 4153 of the *Astronomische Nachrichten* (February 6).

The positions (1905.0) of the comet at the beginning and end of the trail were:—

$$\text{R.A.} = 18\text{h. } 23\text{m. } 16.4\text{s.} \quad \delta = -20^\circ 30'.0$$

at 16h. 20m. G.M.T., and

$$\text{R.A.} = 18\text{h. } 23\text{m. } 41.2\text{s.} \quad \delta = -20^\circ 31'.0$$

at 18h. 55m. G.M.T., respectively; the position angle and length of the trail were found to be 288° 24′ and 368″, thus giving a daily motion amounting to 3m. 49.5s., 17′ 55″. On examining the Harvard plates for this date Miss Leavitt was unable to find any trace of the object, which must have been much smaller than Giacobini's 1905 III comet, and at least six or eight times less bright.

THE SPECTRUM OF MIRA.—Four photographs of the spectrum of Mira were obtained at the Lowell Observatory during the recent maximum of the star's brightness, and a brief discussion of them is published by Mr. V. M. Slipher in No. 1, vol. xxv. (February), of the *Astrophysical Journal*. The first spectrogram, obtained on December 13, 1906, included the region λ 4300 to λ 5000, and shows both Hβ and Hγ as strong, bright lines. The second photograph was taken on December 18, and shows the four hydrogen lines Hα, Hβ, Hγ, and Hδ as bright lines increasing in intensity in the order given, Hα being notably weaker than the others. Numerous absorption bands, sharp and intense on their more refrangible edges and gradually fading out towards the red, are shown, in addition to the hydrogen lines, on the plate taken on December 21. On the last plate, taken December 24, all the hydrogen lines were bright, Hα being bordered on the violet side by a strong and rather broad absorption line. Of the metallic absorption lines those due to vanadium are recorded as being especially strong.

SUN AND PLANET CHART.—We have received, from the firm of Carl Zeiss, 29 Margaret Street, W., a copy of a very useful chart which enables a ready determination to be made of the position of the sun, or of any of the planets, in regard to the fixed stars during 1907. It consists of a chart of the equatorial constellations, together with right ascension and declination curves, on the same scale as the chart, of the objects to be found. By simply drawing ordinates for the required date, as found on the chart, and projecting the points where they intersect the R.A. and declination curves on to the star chart, the relative position of the sun or planet may be determined in less than one minute.

THIRTY-SIX NEW VARIABLE STARS.—By superposing positive and negative copies of six photographs taken with a 1-inch Cooke lens, Miss Leavitt discovered thirty-six new variable stars in a region 30° square, having its centre at R.A. = 12h., dec. = −60°. These variables are mostly situated in the constellations Carina and Centaurus, and six of them are probably of the Algol type. Nova Velorum was discovered, and sixteen known variables were rediscovered on the same plates (Harvard College Observatory Circular No. 122).

SEISMOLOGICAL NOTES.

Valparaiso Seismograms.

ON August 17, 1906, Valparaiso was visited by an earthquake of unusual severity. Seismograms of this disturbance were obtained at all observatories throughout the world which were properly equipped with apparatus to record teleseismic motion. The seismograms obtained in this country, as was pointed out to me by Mr. R. D. Oldham, and noted by other observers, exhibit a dual character. This duality is clearly seen in the annexed seismogram from Kew, reproduced by the kind permission of Dr. R. T. Glazebrook. After preliminary tremors, there is a "shock" or maximum, marked A, at 1.5 G.M.T., and a second "shock" or maximum, marked B, forty-five minutes later, or at 1.50. If the latter shock originated in or near to Valparaiso, and took 1h. 5m. to travel from that part of the world to Britain, it originated there at 7.59 in Valparaiso time. The most accurate time received from Santiago is 7.58.40, or practically 7.59. We may therefore conclude that B represents the disturbance which led to devastation in Valparaiso and places in that vicinity. The question now arises as to what is shock A at 1.5 G.M.T. From the duration of its preliminary tremors it evidently came from some place about 105° distant, which happens to be the situation of Valparaiso, and the time of its origin, wherever that may have been—Central Asia or South America—was in G.M.T. 0h. 0m. (7.14 Valparaiso time), but up to date I am not aware that the inhabitants in Valparaiso know anything about a shock at 7.14. Shock A and shock B may have a direct relationship, or they may be independent disturbances which occurred about the same time. Together they make a jumble which might be compared with the meeting of waves at the mouths of two opposing estuaries. The International Seismological Association, which met last year in Rome, issued from its headquarters in Strassburg a circular to seismological stations generally asking for seismograms of "the Valparaiso earthquake." These and a variety of detail about instruments and the stations where seismograms were obtained are to be placed before the delegates of that association when they meet at the Hague for their study.

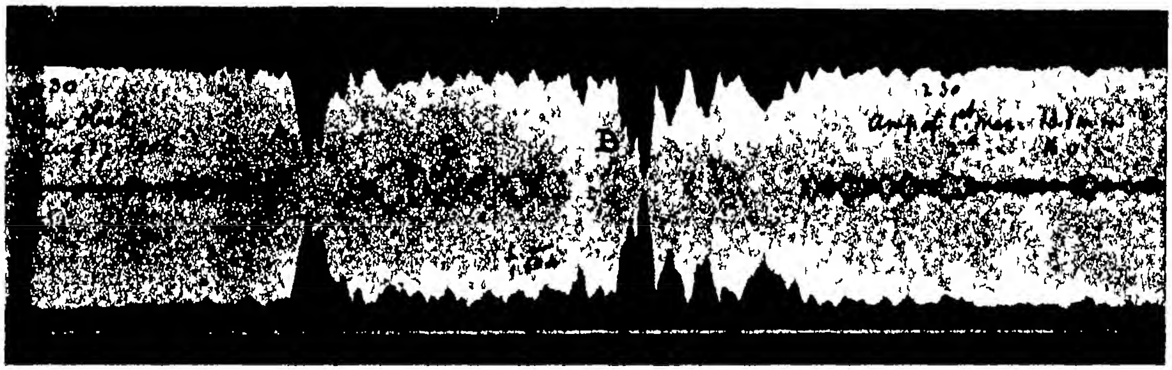
A New Seismometer.

The International Seismological Association offers prizes of 50*l.*, 35*l.*, 25*l.*, and 15*l.* for the construction of a seismometer. It is to record earthquakes which have their origin near to the place of observation, which we assume means earthquakes that can be felt. It must register both horizontal and vertical movements. No doubt the authors of this condition are well aware that vertical displacements are accompanied by angular displacements. Any recording seismometer under the influence of vertical movement at its best becomes an indifferent variety of clinometer. Usually its records have no more value than those from a seismoscope. One remarkable condition is that the new instrument must have a magnification of not less than forty to fifty times. Seismographs used in Japan, and by all who have had experience in recording earthquakes of local origin, find a magnification of from six to ten quite sufficient. If a shock has a range of a quarter of an inch, which in soft ground may well be the case, this

would appear on the record receiving surface of the new seismograph more than a foot or 30 cm in length. It is, of course, possible to construct a large record receiver, but is it necessary? About a record of time, which is probably the most important element required by the working seismologist, nothing whatever is said.

Seismographic and other Record receiving Surfaces.

The record receivers to which I refer are the types used in connection with horizontal pendulums adopted by the British Association, and now in use at many stations widely distributed round the world. Nearly all of these record on a surface of photographic paper moving at the rate of 60 mm. per hour. There are, however, one or two instruments where the paper moves at a rate of about 250 mm. per hour. With very large earthquakes, the times of commencement or the commencement of the preliminary tremors, as recorded on either the slow or comparatively rapidly moving paper, are identical, the seismographs being similar and placed side by side. With earthquakes of moderate intensity this is not always the case. On the slowly moving paper the commencement of the preliminary tremors may be lost. The explanation apparently rests in the fact that slowly moving paper passing beneath two illuminated cross slits or an illuminated "pin-hole" has a longer exposure than that which is moving quickly. The longer the exposure the broader the line. In one case the film takes about twelve seconds to pass beneath the "pin hole," and in the other between two and three seconds.



Seismogram of the Valparaiso Earthquake, August 17, 1906.

In either case, when the boom of the pendulum, which at its outer extremity carries the equivalent of a "pin-hole," is steady, we get a straight line on the film moving beneath the same. Very slight movements of the boom, however, are to be seen on the film which has passed quickly beneath its spot of light which cannot be seen on the film which has moved slowly. On the latter minute ripples have been eclipsed in the broadened line. The meaning of this, not only to practical seismologists, but to all who have to deal with photographic recording apparatus, is that the best result which can be obtained from a given instrument largely depends upon the speed of the photographic record-receiving surface.

JOHN MILNE.

SCIENCE IN INDIA.[1]

THE "narratives" from which extracts have been taken for publication in the report before us are those of officers of the Indian Survey Department who are employed on work of scientific investigation. There is little of topographical, and nothing of geographical, interest in them if we except certain results derived from Captain Wood's mission to Nepal. They afford, however, most convincing proof of the strenuous nature of the work of the scientific branch of the department, and should serve amply to justify the maintenance of a well-matured system of scientific investigation in the eyes of those critics who are disposed to assert that India cannot afford to be scientific.

No less than 128 pages out of the 187 which comprise the report are devoted to the reproduction of tables giving the results of magnetic observations, which are further illustrated by a map showing the stations of observation of the magnetic survey. Since the year 1901, these have been carried practically over the whole peninsular area with the exception of the Central Provinces. A description of some of the stations and of the instruments used completes the narrative, but no general deductions are made, nor is any indication afforded as to the practical result of these undoubtedly valuable observations.

Major Conyngham's report on the pendulum observations for determining the force of gravity is directly interesting. The latest instrumental equipment for this class of observation includes "half-second" pendulums, which are only one-quarter the length of those previously used in the department. A new method (an Austrian invention) has also been introduced for registration of the coincidence of beat between the free pendulum and the clock pendulum, the pendulums being no longer swung *in vacuo*. A considerable increase in accuracy of observation has thus been assured, further refinements being introduced in the corrections applied for the minute vibrations (or "wagging") of the stand on which the instrument is fixed due to the swing of the pendulum. Some of the results are curious. For instance, it was found at Calcutta that the perpetual tremor, or vibration, set up by traffic, due to the nature of those alluvial deposits on which the city may be said to be floating, absolutely negatived the value of the observations, whilst, on the other hand, observations taken at Colaba, in Bombay, were not affected appreciably by the firing of the big guns of the fort in their vicinity.

The value of "g" (force of gravity) being used to determine the figure of the spheroid and the density of the earth's crust, it was found at Colaba that the excess of attraction indicated by the observations equalled that which would be accounted for by a disc of earth matter below the instrument 2530 feet thick with an excess of density equal to 2.8 above the average of surface density. At Dehra Dun on the other hand the defect in "g" indicated a deficiency in density of 2.8 extending to 2930 feet in depth. Assuming that the surface density is 2.8, this means that we must imagine a cavity 2930 feet deep under Dehra Dun, in other words, "the matter underlying Dehra Dun is so deficient in density—we do not know to what depth this deficiency may extend—that it would have to be pressed downwards until the surface of the land was 2930 feet below its present position before it would attain the average density of the crust of the earth. Likewise at Colaba an expansion of the underlying strata until a hill 2500 feet high had been formed would be requisite to reduce the excessively dense rock that is found here to the average density of 2.8."

Certain levelling operations referred to in another part of the report have been undertaken in the interests of these

[1] "Extracts from Narrative Reports of Officers of the Survey of India for the Season 1903-04." Pp. 187. (Calcutta.)

pendulum observations to determine the difference of level between Dehra Dun and Mussoorie

Valuable results still continue to be obtained from the tidal observations, which extend over forty-two ports from Aden to Port Blair Tide tables for forty ports are now published in England based on the observations of the Indian Survey Several instructive tables will be found in the report, especially those showing the errors in the predicted times and heights of high and low water at the various stations These tables apparently indicate a superiority in the automatic system of recording

Amongst the most interesting records of the season are the results obtained by a careful re-computation of Captain Wood's observations for determining the position of Everest and other high peaks in Nepal The more rigorous methods employed give a very slight difference (never amounting to half a second of arc) between the new and old determinations of the coordinate values of the stations of observation, which differences are reflected in a greater degree in the values of the peaks observed, but the corrections in altitude of the peaks observed, due to the employment of a revised coefficient for refraction, are more marked The height of Mount Everest, for instance, is reduced by about 300 feet (28,700 feet instead of 29,000 feet), and a general reduction in altitude of most of the peaks is apparent This, however, must not be accepted as a final determination There are other factors in the computation of altitudes observed under extraordinary conditions still to be determined with more rigorous exactness, and it is quite possible that the ultimate altitude of the highest mountain in the world may be fixed at a higher figure than 29,000 feet rather than a lower one

A short statement of the progress of topographical surveys in Sind (with no narrative of any interest) and of riverain surveys in the Punjab with a few notes on town and municipal surveys generally, completes the report

THE NEEDS OF THE UNIVERSITY OF CAMBRIDGE

TEN years ago the Duke of Devonshire, as Chancellor of the University of Cambridge, directed attention to the resources and the needs of the University, and at the beginning of 1899 the Cambridge University Association was formed The progress towards the re-endowment of the University, which it is the object of the association to promote, is described by the Chancellor in a letter of which a copy has been sent to us, and is here summarised

The sums which the Cambridge University Association has been able to transfer to the University amount in all to about 115,000*l* Of this total a considerable portion was allotted by the donors to the building of the new medical school, the school of engineering, the proposed new buildings of the Cavendish Laboratory, the school of agriculture the museum of archæology and ethnology, and to the University library, but a large proportion has been available for general purposes

Although the progress already made in the equipment of the several departments must be regarded with satisfaction few of the other wants keenly felt in 1899 have yet been met, and in certain cases new wants have inevitably arisen during the last seven years In the scientific departments every year must of necessity bring new demands for specialisation in teaching and for the provision of facilities for research In some departments, notably those of agriculture engineering, and chemistry, the number of students has greatly increased, and additional accommodation is required

The greater of the immediate needs of the University may thus be stated The sum of 18,000*l* promised for the University library represents only the first instalment of a capital sum of 148,000*l* required Chemistry requires 10,000*l* capital and 2000*l* income, physics, 12,000*l* capital and at least 1000*l* income engineering, 10,000*l* capital, and income and equipment for research, botany, 1000*l* capital and 250*l* income, physiology 10 000*l* capital and 1800*l* income, agriculture, 20 000*l* capital (of which 12 000*l* has been promised) and 600*l* income, the medical school will cost at least 20,000*l* to complete, and in addition a considerable sum is needed for the provision of instruments, &c, and a large income for additions to the teaching staff Geology asks for 2800*l* capital and 1300*l* income A new, or at least a greatly enlarged, museum of zoology will shortly become necessary, and an income of 1500*l* is also required for this subject Entomology, a subject of great importance in its relations to forestry and tropical medicine, is in need of 10,000*l* capital Oriental studies require 2000*l* income A new museum of archæology and ethnology, urgently needed for the preservation, and for the display for the use of researchers, of the valuable collections possessed by the University, will cost 25,000*l*, and a considerable income will be required for staff and maintenance History is in need of 800*l* income, and a sum for the provision of lecture rooms Economics require 2000*l* income, the moral sciences (including experimental psychology) 1400*l* capital and 1250*l* income Classics require about 900*l* income and mathematics capital for new lecture-rooms and 3500*l* income Law asks for 600*l* income Modern languages urgently require a sum sufficient to create professorships in at least English, French, and German (at present represented by two readers and a lecturer), and to ensure the proper representation of other modern languages There are other needs, some of them not intrinsically less important than those mentioned, but demanding more modest sums for their satisfaction

The disabilities arising from the low scale of existing salaries are common to almost every department The average stipend of a professor is but 550*l*, and that of a university teacher, other than a professor, 250*l* per annum and these figures include the emoluments received from fellowships and from fees The disability is increased by the fact that the University *can set aside only 200l per annum to form a pension fund for its forty-four professors*, and nothing at all for other teachers There is, in addition, need for the creation of many new posts

If the University is to retain the services of its most distinguished men it is imperative that the income assured to them both during and after the period of active work, should bear comparison with what they may obtain in similar positions elsewhere

It is stated that in all a capital sum of nearly one million and a half, apart from any question of a pension fund for professors might without extravagance be immediately expended on the equipment of, and on the provision of staff for the University

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —The professorship of agriculture in the University was established in the year 1899, in consequence of a generous offer by the Drapers' Company to contribute 800*l* a year for ten years to the agricultural education fund, for the stipend of the professor The Drapers' Company has now signified its intention to continue its contribution of 800*l* a year for a further period of ten years, dating from the year 1909, on the understanding that the Department of Agriculture, and the stipend of the professor, shall be maintained as at present. The company has further expressed approval of a suggestion made by the board of agricultural studies, that the source of the endowment should be indicated, as in the case of some other foundations, by attaching to the chair the title of the "Drapers' Professorship of Agriculture"

The following have been appointed members of the board of electors to certain professorships —Dr Keynes and Mr W E Johnson, of King's College to that of the Knightsbridge professorship of moral philosophy, Mr F H Neville, of Sidney Sussex College, to that of the professorship of chemistry and to that of the Jacksonian professorship of natural philosophy, Prof Forsyth, to that of the Plumian professorship of astronomy, Prof Howard Marsh, to that of the professorship of anatomy Prof S H Vines, to that of the professorship of botany, Dr Bonney, to that of the Woodwardian professorship of geology and to that of the professorship of mineralogy; Sir Thomas Barlow, Bart, to that of the Downing pro-

fessorship of medicine, Dr Gaskell, to that of the professorship of zoology and comparative anatomy, Dr Keynes, to that of the professorship of political economy, Dr W N Shaw, to that of the Cavendish professorship of physics; Prof. J J Thomson, to that of the professorship of mechanism and applied mechanics, Prof C S Sherrington, to that of the professorship of physiology, Prof. Nuttall, to that of the professorship of pathology, the Hon. B A W Russell, to that of the professorship of mental philosophy and logic, and Mr A. E Shipley, of Christ's College, to that of the professorship of agriculture.

The teachers' training syndicate has appointed Dr Rouse, of Christ's College, O Browning, of King's College, and J Wallis, of Christ's College, as delegates to attend the International Congress on School Hygiene to be held in London next May

PROF. H McLEOD, F R S, is to receive the honorary degree of LL D from the University of St Andrews at the graduation ceremonial on April 2

PROF. THOMAS LOVEDAY, professor of philosophy at the South African College, Cape Town, has been appointed librarian to the University of Sheffield

ARRANGEMENTS have been made for establishing a distinct department of the Board of Education to deal with all grades of education in Wales and Monmouthshire Mr A T Davies has been appointed permanent secretary of this Welsh Education Department, and Mr O M Edwards chief inspector for Welsh education, and both will be directly responsible to the president

A REUTER message from Pittsburg announces that the Western University of Pennsylvania will confer the honorary degree of LL D upon the following gentlemen, among others, who will be present at the Founders' Day celebrations of the Carnegie Institute on April 13 next — Sir Robert Ball, Sir William Turner, K C B, Sir William Preece, K C B, Signor Marconi, Mr Chalmers Mitchell, Dr John Rhys, and the Rev E S Roberts, master of Caius College, Cambridge

A RECENT issue of *Science* contains further striking instances of the importance attached to higher education by wealthy American citizens Rensselaer Polytechnic Institute has received a gift of 200 000*l* from Mrs Russell Sage The money will be used for the school of mechanical and electrical engineering Mrs Sage has also given 200,000*l* to the Emma Willard School of Troy The establishment and permanent endowment of Peabody College for Teachers, at Nashville, Tennessee, has also been assured The Tennessee legislature has just passed a Bill providing the college with 50,000*l* The city of Nashville has given 40,000*l*, and the county of Davidson 20,000*l* These gifts have been made in response to a proposition from the Peabody Education Board to endow the college with 200 000*l* All the conditions imposed by the Peabody Board have now been complied with, and it only remains for that board to organise the institution The college will have 310,000*l* in money In addition to this, the University of Nashville has given the grounds and buildings now occupied by the college, valued at 50,000*l* It is understood also that gifts will be received at once from other sources amounting to about 200,000*l* We also notice that by the will of Arthur Mills, of Brookline, Harvard University will ultimately receive 30,000*l*

IT is satisfactory to learn from the annual report that the Geographical Association, which is doing very useful work in promoting the study of geography in schools by scientific methods, is making substantial progress In many schools geography is still regarded as a collection of names and phrases which convey no real meaning to the pupils but, thanks largely to the efforts of the association, both teachers and examiners are beginning to realise that geography must be approached in the spirit of practical inquiry if it is to be of any value as a school subject Ordnance Survey maps can now be obtained by schools at greatly reduced prices upon application to the Director General of the Ordnance Survey Southampton, and suitable maps to supplement these will no doubt be suggested by the committee appointed by the association to consider the substance and scope of atlases for elementary schools A special committee on lantern-slides has also been appointed This committee hopes to prepare series of slides illustrative of certain aspects of geography, as well as of various countries It is specially anxious to obtain sets of views of different districts in the United Kingdom illustrative of their scenery and social conditions, as well as from British and other lands beyond the seas Such illustrations, combined with exercises on the construction and use of maps, practical measurements with tape and plane-table, meteorological observations recorded day by day, and the spirit of "Seek and ye shall find" permeating the whole of the work, will transform geography from a dismal study into a living science by which both the imaginative and the critical faculties may be cultivated We have no sympathy with the old order of things, but the change which the Geographical Association is bringing about gives decided satisfaction

THE provisional programme of the Federal Conference on Education, organised by the League of the Empire, and to be held in London from May 24 to June 1, includes the following educational subjects —Teachers (1) comparison of (*a*) the provisions for the supply and the training of elementary teachers, and of (*b*) the conditions of their work in the United Kingdom and other countries of the Empire and Crown colonies, (2) similar comparison in the case of secondary teachers, (3) practicability of temporary interchange of teachers and of inspectors between the United Kingdom and other countries of the Empire and Crown colonies The relations between secondary and primary schools in the various countries of the Empire Means of establishing a system of mutual recognition of equivalent standards of attainment in the several countries of the Empire in connection with primary, secondary, and university education Cooperation in educational publications (1) scheme of the League of the Empire for Imperial text-books in history, (2) means for ensuring correctness in text-books dealing with geography, or in which local knowledge is required Cooperation in school work (1) the formation of a central exhibition of industrial or other school work, (2) the organisation of the exchange of school work and specimens between departments, museums, and between individual schools on a permanent basis School subjects (1) the English language (*a*) reading (literature), (*b*) composition (*c*) pronunciation, (2) geography in its relations to (*a*) history (*b*) discovery and commerce, (*c*) the growth of the Empire, illustrated by lantern slides and other means (3) encouragement of nature-study Education of non-British races comparison of ideals methods and standards in various parts of the Empire Other subjects which may be discussed if time allows (*a*) cadet corps and military training, (*b*) educational facilities in sparsely populated districts, (*c*) educational treatment of poor law and reformatory children (*d*) civic and moral education (*e*) metric system of weights and measures, (*f*) school gardens

SOCIETIES AND ACADEMIES.

LONDON

Mineralogical Society, January 29 —Prof H A Miers, F R S, president, in the chair —Experiments bearing on the order of crystallisation of rock-constituents Prof H A **Miers**. The general results of experiments made by Miss F Isaac and Prof Miers with mixtures of salol and betol in all proportions were described, the experiments have established the supersolubility curves even beyond the points where they cross below the eutectic temperature Owing to the fact that the main separation of crystals in the cooling mixtures takes place only when the liquids have been supercooled to temperatures given by the supersolubility curves, it has been found (1) that in general the mixtures do not solidify as a eutectic mixture, (2) that, according to the conditions of supercooling either substance could be made to crystallise before the other in mixtures approaching the eutectic in composition It was suggested that these results are applicable to the solidification of many rocks and alloys —Serpentine rock

from the Larnthaler Kopfe, Tyrol Dr A P **Young** The minerals found in the serpentine are diopside, tremolite, clinochlore, picotite, magnetite, iron pyrites, and a fibrous mineral referred to antigorite The latter mineral is regarded as holding a place between the micas and chlorites On the surface of the serpentine are projecting bastite pseudomorphs coated with films of silvery lustre The serpentine is a non-foliated intrusive core which on the borders is highly foliated and passes into talc bearing phyllites A simple tabular arrangement of the thirty two crystallographic classes Dr J W **Evans.** The table is based on the character of the symmetry of the principal zone axis or zone axes Each column contains classes with the same rotational symmetry round the axis, and each row those which agree in the other symmetrical characters of the axis A new model of crystal refractometer Dr G T Herbert **Smith** This instrument is identical in principle with that previously described and is intended for use with large mineral specimens and mounted gem stones No part extends above the level of the plate holding the dense glass hemisphere Further the optical combination has double the focal length of the earlier form and provides consequently, greater refinement —Isomorphism as illustrated by certain varieties of magnetite Prof B J **Harrington** Analyses are given of specimens of magnetite from St Joseph du Lac, Canada, and from Magnet Cove, Arkansas, both showing the unusual combination of octahedron and trapezohedron {311} The Canadian specimen contained about 5 per cent of TiO_2 8 per cent of MnO, and 3 per cent of MgO and the specimen from Arkansas about 10 per cent of Al_2O_3, 2 per cent of TiO_2 2 per cent of MnO and 0 per cent of MgO —Mr **Fleischmann** exhibited a collection of zeolites from Japan, Dr **Evans** an objective giving a flat field with convergent light and Prof **Miers** a goniometer to be used for the measurement of the refractive indices of cooling solutions for which purpose it is provided with means for maintaining a constant temperature for any desired period

Zoological Society February 5 —H G the Duke of Bedford K G, president in the chair —Mammals collected in Mindanao Philippines, by Mr M P Anderson for the Duke of Bedford's exploration of eastern Asia O **Thomas** Seven species were mentioned, one of which was new and is designated *Crunomys melanius* sp n The origin of the lateral horns of the giraffe in fœtal life on the area of the parietal bones Prof E Ray **Lankester** The author described and showed the exact relation of the lateral horns in the fœtus taken from the giraffe which died last spring in the society's gardens It was demonstrated that the lateral horn of the giraffe was exclusively in origin a part of the fibrous osteogenetic tissue of the parietal bone of which it was a part and had no connection whatever with the frontal Thus the statement made by Sir Richard Owen in his account of a new born giraffe, in a paper read before the society in 1839 was finally shown to be based on an unfortunate accident Owen had cut out the horn-bearing area of the skull, and after an interval of time had reversed the relations of the excised piece of bone, taking frontal for parietal and parietal for frontal The author expressed the opinion that the *parietal* lateral horn of the giraffe could not be considered to be the same morphological unit as the frontal lateral horn of the okapi —Parallel hair fringes and colour striping on the face of fœtal and adult giraffes Prof E Ray **Lankester** The author described a remarkable colour banding or striping of the hairy covering of the face in the fœtal giraffe and showed that similar dark and light striping occurred in a very marked form in adult giraffes though not in all individuals —The existence of rudimentary antlers in the okapi, Prof E Ray **Lankester** A description was given of the polished tip or apex of the okapi's horn which breaks through the integument The author showed that transverse fissures or incisions were produced one behind the other in the naked apex tending to cut off in succession a series of small bony caps, which he regarded as rudimentary antlers He expressly refrained from concluding that this formation of minute antler-caps was to be regarded as genetically connected with the antler formation of the Cervidæ, though such a connection was possible —A new Amazonian tree-frog, *Hyla resinifictrix*, closely related to *H venulosa*, but distinguished by fully half-webbed fingers G A Boulenger, on behalf of Dr E A **Goeldi** This frog was remarkable for its habit of making good-sized basins of resinous substances in hollow branches of high trees, in which water collects, which served as a nursery for the eggs and larvæ The frog collected the resin from the bark of certain trees, such as the aromatic brewbranco" (*Protium heptaphyllum*) —The collection of Cumacea in the Copenhagen Museum Dr W. T **Calman** Altogether thirty species were dealt with, of which twenty-five were described as new The majority of the specimens were derived from collections made in New Zealand and the Gulf of Siam by Mr H Suter and Dr Th Mortensen respectively

Chemical Society, February 7 —Prof R Meldola, F R S, president, in the chair —The rapid electro-analytical deposition and separation of metals, part 1, the metals of the silver and copper groups and zinc H J S **Sand.** The metals studied are silver, mercury, copper, bismuth, lead, cadmium, and zinc With the exception of the separation silver-mercury, each metal has been successfully separated from all the others by the method of graded potential In order to separate silver from mercury, the metals were deposited together, converted into their cyanides, and these separated in the usual way by means of their different behaviour to acids The time required for the depositions in these experiments varied between five and fifteen minutes —The alkaloids of ergot G **Barger** and F H **Carr** It is shown that ergotoxine, $C_{35}H_{41}O_6N_5$, is the active principle of ergot, and Kraft's assertion that the crystalline alkaloid ergotinine, is a dehydrated ergotoxine is confirmed Ergotinine is physiologically inactive when pure —Influence of substitution on the formation of diazoamines and amino azo-compounds, part vi the partially methylated 4 6-diamino-*m* xylenes G T **Morgan** and Miss F M G **Micklethwait.** The authors have methylated progressively 4 6-diamino *m* xylene, and have studied the action of diazonium salts on the products —The constitution of umbellulone, part ii, the reduction of umbellulonic acid F **Tutin** By further study of the oxidation products of this ketone further confirmation of the constitutional formula originally assigned to it has been obtained —The reduction of hydroxylamino dihydroumbellulonoxime F **Tutin** Derivatives of aminotetrahydroumbellulylamine obtained by the reduction of this oxime are described Studies on optically active carbimides, part v the aryl esters and the amides of *l* menthylcarbamic acid R H **Pickard** and W O **Littlebury** Eleven aryl esters and eighteen amides of *l* menthylcarbamic acid were described, and rotations of these when dissolved in chloroform and pyridine compared Attention was directed to the approximately constant molecular rotation given by certain derivatives of menthylamine and menthol —Some constituents of natural indigo, part i A G **Perkin** and W P **Bloxam** Three brown amorphous substances $C_{14}H_{12}O_2N_2$, $C_{24}H_{22}O_6N_4$, and $C_{16}H_{14}O_4N_2$ are described, which on treatment with potassium hydroxide yield anthranilic acid It is considered possible that these brown compounds are derivatives or condensation products of indoxyl which are formed from indican during the process of manufacture —The occurrence of isatin in some samples of Java indigo A G **Perkin** The quantity of isatin present was exceedingly small, and in many samples it appeared to be absent but its occurrence occasionally is interesting, as it indicates that the formation of indirubin during the manufacture of natural indigo follows the well-known synthesis of von Baeyer —The absorption spectra of benzoic acid, the benzoates, and benzamide W N **Hartley** and E P **Hedley** The absorption curves of benzoic acid, potassium and silver benzoates and benzamide have been drawn from the photographs of the spectra of these substances The absorption bands of the different substances are all obviously related to the bands in benzoic acid, and the absorption is due to the benzene ring (compare Baly and Collie Trans Chem Soc, 1905 lxxxvii 1332) —The absorption spectra of phthalic isophthalic, and terephthalic acids, phthalic anhydride, and phthalimide

W N **Hartley** and E P **Hedley** *o*-Phthalic acid gives an absorption curve of the character that might be expected from a comparison with that of benzoic acid *iso*Phthalic acid has a shallow band in the same position as that of phthalic acid, but less persistent Terephthalic acid has no band, but merely an extension at or near where a band might be expected—ααγ-Trimethyl- and ααγγ-tetramethyl-tricarballylic acids and αδ-dimethylbutane-αβδ-tricarboxylic acid H **Henstock** and C H G **Sprankling.**—A reaction of certain colouring matters of the oxazine series J F **Thorpe**—The alkylation of *d*-fructose T **Purdie** and D McLaren **Paul** The series of derivatives of fructose obtained by methylating this ketose is described—A simple apparatus, with stirrer, for treating a liquid at its boiling point with two or more gases N L **Gebhard.**—Note on the arsenates of lead and calcium S **Pickering**—Camphor-β-sulphinic acid and camphorylsulphonium bases S **Smiles** and T P **Hilditch.** The sulphinic acid and the sulphonium bases prepared exhibit a strong lævorotatory power in distinction from the dextrorotatory sulphonic acid from which they were obtained The authors conclude that this change is caused by the conversion of the sulphur from the sexavalent to the quadrivalent state—The condensation of salicylamide with aryl aldehydes C A **Keane** and W W S **Nicholls** Benzaldehyde, when heated with salicylamide in presence of hydrochloric acid or of sodium acetate, condenses to form a cyclic compound of the oxazine group, namely, 2-phenyl-1 3-benzoxazone Homologues of this were prepared by condensing salicylamide with anisaldehyde and *o*-methoxybenzamide with benzaldehyde—The condensation of diethylmalonamide with aldehydes H **Burrows** and C A **Keane** Diethylmalonamide, when heated with benzaldehyde in presence of hydrochloric acid, condenses similarly to salicylamide (see note on preceding paper) to form a cyclic compound of the pyrimidine group, 4 6-diketo-2 phenyl 5 5-diethyl hexahydropyrimidine

Mathematical Society, February 14—Sir W D Niven, vice-president, in the chair—Prof A R **Forsyth** gave an account of the life and scientific work of the late Colonel A Mannheim an honorary foreign member of the society—Repeated integrals Dr E W **Hobson** When Riemann's definition of integration is adopted, it may happen that the double integral of a function does not exist, although the repeated integral does exist if the integrations are performed in a certain order The more extended definition of integration introduced by Lebesgue throws light on this and other anomalies in the theory of the relations of double integrals to repeated integrals The projective geometry of a binary quartic and its Hessian Prof E B **Elliott.** The quartic is regarded as the equation of four straight lines drawn through the origin, and is represented by the four points in which these lines meet a chosen conic drawn through the origin The original quartic and its Hessian are members of a pencil of quartics, each represented by four points on the conic, and all the quadrangles which are thus obtained have the same harmonic triangle Any quadrangle of the set is determined by the harmonic triangle and one vertex of the quadrangle With this vertex a certain point on a chosen side of the harmonic triangle can be associated by a linear construction, and the quadrangle is determined by this point and the harmonic triangle The determining point for the Hessian can be associated with that for the original quartic by a linear construction which is given in the paper—A formula for the sum of a finite number of terms of the hypergeometric series when the fourth element is equal to unity Prof M J M **Hill** The formula includes the well-known expression for the sum of the series, and gives an exact value for the remainder after *s* terms—Groups defined by the order of two generators and the order of their commutator Prof G A **Miller**—An informal communication on hyper exponential numbers was made by Lieut-Colonel A **Cunningham**

DUBLIN

Royal Irish Academy, January 14—Dr F A Tarleton, president, in the chair—Infection of bovines by the avian tubercle bacillus Prof **Mettam** The paper gave an account of experiments with cultures of avian tubercle bacillus Injected into the auricular vein of a heifer, the virus produced a fatal infection In the other experiment a portion of a culture was given by the stomach-pump to a young bull The animal became infected as shown by the tuberculin test It recovered from the infection, however, because just prior to slaughter the animal was re-tested, but did not respond, and the lesions found at *post mortem* were sterile, and failed to produce a lesion in the rabbit in which they were inoculated Both animals were shown to be free from tuberculosis prior to experiment by the use of tuberculin The same author also read a note upon the development of tubercles in the lacteals of the villi of the small intestine in rabbits infected by feeding with tuberculous material from a bovine source The tubercle has the same anatomical structure as that developing in the pulmonary capillaries or liver sinusoids—epitheloid cells of mononuclear leucocyte origin, lymphocytes, and giant cells The epithelium of the villus may be intact—The general solution in integers of the indeterminate equation $aX^3+bY^3+cZ^3+dXYZ=0$ Dr T **Stuart.** The solution of this equation (or of special cases of it) has been considered by Sylvester, Lucas, Desboves, and other writers The only known method (save that of trial) for finding a solution is by means of artificially constructed identities In this paper the various identities and theorems obtained by previous writers are coordinated and shown to be deducible from elementary geometrical considerations, and some statements of Sylvester and Desboves are also shown to require considerable modification The geometrical method of attacking the problem leads to important results in high factorisation

January 28 The river Shannon its present regimen and geological history J R **Kilroe** The river admits of easy navigation falling only about 150 feet in 140 miles It commenced to flow upon a plain of post-Eocene date 2500 feet to 3000 feet above present datum and a very trifling inclination to the north west or south would have permanently deflected the drainage Retention of its course alone could have kept the gorge at Killaloe open but at some time shortly prior to the Glacial epoch the river seems to have abandoned the gorge until the ancient bed by Killaloe was lowered at certain points below the sea-level by glacier erosion Upon the disappearance of the ice the river resumed its original course

PARIS

Academy of Sciences, February 11—M A Chauveau in the chair—The preparation of alkylcampholic esters and on a new method of formation of phenyloxyhomocampholic acid A **Haller** and Charles **Weimann** The cyanocampholic esters treated with alkyl magnesium iodides yield imido-compounds, the latter with sulphuric acid, giving ketones The cyanogen group of the cyanocampholic ester is here replaced by the group —COR, R being the alkyl group of the magnesium compound Numerous examples of the application of this reaction are given—The mechanism of the transformations in normal media of the Crustaceæ E L **Bouvier** At the commencement of the Quaternary epoch the formation of the Isthmus of Panama caused a separation of the crustaceans in this region and each group has developed in a normal medium since that time Typical species are compared to show the amount of the differences which have arisen during this period—Has the African elephant a pleural cavity? Alfred **Giard** The *post-mortem* examination of an African elephant, recently described by Mme M Phisalix, would appear to show that the African elephant has a pleural cavity In the case of the Asiatic elephant there is clear evidence that the visceral and parietal layers of the pleura are closely connected together by matted elastic tissue and it is highly probable that this is also the case in the African elephant The diagnosis of pleurisy on account of thickness of the pleura and its adherences would, therefore appear to be a mistaken one—Various syntheses of dimethylisopropyl-carbinol Louis **Henry** The α-chloro-*iso*butyric aldehyde reacting with magnesium methyl bromide gives the expected pinacolic alcohol but its tertiary isomer, dimethyl*iso*propyl carbinol A theory of this reaction, supported by experimental facts is proposed—Observations of the sun made at the Observatory of Lyons during the fourth quarter of 1906 J

Guillaume The results are summarised in three tables showing the number of spots, their distribution in latitude and the distribution of the faculæ in latitude.—The problem of Dirichlet H **Lebesgue**—The non applicability of two continuous regions of n and $n+p$ dimensions René **Baire**—The channelled spectra of parallel gratings Georges **Meslin** A mathematical discussion of the various hypotheses which have been proposed in this connection, and in particular that due to M Garbe whose theory is shown to give a complete explanation of the phenomena —A singular state of matter observed in a dissolved chromic salt Albert **Colson**—The alkylation of metallic cyanides H **Guillemard**—The catalytic reduction of unsaturated ethyl esters G **Darzens** An application of the Sabatier and Senderens reaction to the preparation of ethyl propionate isovalerate, and pelargonate from the corresponding unsaturated esters The addition of two atoms of hydrogen to a whole series of acids of the type $R(CH_2)C\ CHCO_2H$ a general method for the preparation of which is described can also be effected in this way Examples of the application of the method in the aromatic and hydroaromatic series are also given —The transformation of primary saturated alcohols into the corresponding monobasic acids H **Fournier** Alkaline permanganate has been shown to give oxalic acid with some primary alcohols The author shows that if the conditions prescribed by him are followed, a yield of acid amounting to 75 per cent of the theoretical can be obtained —The presence of aldehydes in cheese and the part played by them in the formation of bitterness A **Trillat** and M **Sauton** Experiments are given establishing the presence of aldehydes in cheese and also the existence of a relation between the quantity of aldehydes and the bitterness of the cheese —Alternating currents of varying periods corresponding to musical sounds the physiological effects of rhythmic alternating currents Maurice **Dupont**—Remarks on the preceding paper by M **d'Arsonval**—Some phenomena of biological adaptation by rhythmical anticipation H **Piéron**—Ether anæsthesia parallel with chloroform anæsthesia Maurice **Nicloux** A quantitative study of the distribution of ether in various organs of the body during anæsthesia These quantities are greater with ether than with chloroform, and the ether is eliminated more rapidly —Lymphosarcoma in the dog A **Borrel**—The discovery of the marine Aquitanian in the middle part of the Rhone valley L **Joleaud**—Some geothermal measurements effected in the Pas-de-Calais basin Félix **Leprince Ringuet.**

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 21

ROYAL SOCIETY, at 4 30 — The Estimation of Chloroform in the Blood of Anæsthetised Animals G A Buckmaster and J A Gardner —On Electrical Seed Testing Prof T Johnson —On Longitudinal Symmetry in Phanerogamia Prof Percy Groom —On the Inheritance of Flower Colour in *Antirrhinum majus* Miss M Wheldale

ROYAL INSTITUTION at 3.—The Minute Structure of Igneous Rocks and their Significance Alfred Harker, F R S

CHEMICAL SOCIETY at 8 30 —The Constitution of Oxyazo-compounds W B Tuck —The Influence of Solvents on the Rotation of Optically Active Compounds, Part ix , A New General Method for Studying Intra molecular Change T S Patterson and A McMillan —The Reduction Products of ortho and para Dimethoxybenzoin J C Irvine and A M Moodie —Replacement of Halogens by Hydroxyl, i , The Hydrolytic Decomposition of Hydrogen and Sodium Monochloroacetates by Water and by Alkali and the Influence of Neutral Salts on the Reaction Velocities G Senter —The Reaction of Ammonium Salts with the Constituents of the Soil A D Hall and C T Gimingham

LINNEAN SOCIETY at 8 —The Percy Sladen Trust Expedition to the Indian Ocean Introduction, Part 1, Ceylon to Mauritius J Stanley Gardiner —Land Nemerteans with a Note on the Distribution of the Group R C Punnett —Land Crustaceans L A Borradaile —Hymenoptera P Cameron —Dragon Flies F F Laidlaw —Fourmis des Seychelles, Admirantes Farquhar et Chagos Prof A Forel —Pycnogonidæ G H Carpenter

INSTITUTION OF ELECTRICAL ENGINEERS at 8 —Lecture on "Modern Theory of Conduction of Electricity in Metals Prof J J Thomson, F R S

FRIDAY, FEBRUARY 22

ROYAL INSTITUTION, at 9 —Flame in Gas and Petrol Motors Dugald Clerk

PHYSICAL SOCIETY, at 5 —Transformer Indicator Diagrams Prof Lyle —Ionisation of Gases by a Particles of Radium Prof Bragg —A Micro manometer B Roberts

INSTITUTION OF CIVIL ENGINEERS, at 8 —Impurities in Boiler Feed water, their Nature, Effect and Elimination F E Walker

SATURDAY, FEBRUARY 23.

ROYAL INSTITUTION, at 3 —Röntgen, Kathode, and Positive Rays Prof J J Thomson, F R S

THE ESSEX FIELD CLUB (at Essex Museum of Natural History, Stratford), at 6 30.—Notes on Dr Fletcher's Report on the Sanitary Circumstances of the Village of Coggleshall T V Holmes —Botanical Surveying in Brittany, an Account of Ecological Work on the Bouche d'Erquy. T G Hill

MONDAY, FEBRUARY 25

ROYAL GEOGRAPHICAL SOCIETY, at 8 30 —Inland Waterways G. G. Chisholm.

INSTITUTE OF ACTUARIES, at 5 —Comparative Bonuses under Whole Life and Endowment Assurances H J Rietschel.

TUESDAY, FEBRUARY 26

ROYAL INSTITUTION at 3 —The Visual Apparatus of Man and Animals: Prof William Stirling

INSTITUTION OF CIVIL ENGINEERS, at 8 —On the Limits of Thermal Efficiency in Internal Combustion Motors: Dugald Clerk

WEDNESDAY, FEBRUARY 27

GEOLOGICAL SOCIETY, at 8 —On the Lower Ordovician Succession in Scandinavia W. G Fearnsides —The Occurrence of Pseudomorphous Pebbles of Pyrites at the Crown Reef Mine, Witwatersrand C. Baring Horwood

SOCIETY OF ARTS, at 8 —Modern Type-writers and Accessories Arthur E Morton

THURSDAY, FEBRUARY 28

ROYAL SOCIETY, at 4.30 —*Probable Papers* On the Dispersion in Artificial Double Refraction L. N G Filon —The Occlusion of the Residual Gas by the Glass Walls of Vacuum Tubes A. A Campbell Swinton.—The Theory of Correlation for any Number of Variables, treated by a New System of Notation G Udny Yule

SATURDAY, MARCH 2

ROYAL INSTITUTION, at 3 —Röntgen, Kathode, and Positive Rays Prof. J J Thomson, F R S

SCHOOL MATHEMATICS

(1) *Trigonometry for Beginners* By J W. Mercer Pp. xi+351 (Cambridge University Press, 1906) Price 4s

(2) *Trigonometry for Beginners* By Rev J B Lock and J. M Child Pp vii+195 (London · Macmillan and Co, Ltd, 1906) Price 2s 6d

(3) *Geometry an Elementary Treatise on the Theory and Practice of Euclid* By S O Andrew Revised edition Pp xii+218 (London John Murray, 1906.) Price 2s

(4) *Modern Commercial Arithmetic* Part 1 By G. H Douglas Pp. 163 (London. Macmillan and Co, Ltd, 1906) Price 1s 6d

(5) *A New Shilling Arithmetic* By C Pendlebury, assisted by F E Robinson Pp xii+176+xxxiv (London · George Bell and Sons, 1906) Price, with answers, 1s 4d

(6) *Junior Arithmetic Examples* By W G Borchardt Pp viii+171+xl (London Rivingtons, 1906.) Price 1s 6d

(7) *Clive's New Shilling Arithmetic* Edited by Dr W Briggs Pp viii+160. (London W B Clive, University Tutorial Press, Ltd, 1906) Price 1s

(8) *Junior Practical Mathematics* By W J Stainer Pp x+350 (London George Bell and Sons, 1906) Price 3s.

(9) *A Rhythmic Approach to Mathematics* By Edith L. Somervell, with a preface by Mary Everest Boole Pp 67 (London George Philip and Son, Ltd, 1906) Price 2s 6d net

(1) MR MERCER possesses a fine conception of how trigonometry should be presented to youths, and his book is admirable and altogether good The development of the subject is very gradual indeed and is constantly enforced by means of concrete examples, systematic computations, practical geometry, and by judicious graphs Thus the first ten chapters are confined to the development of the simple trigonometrical ratios, that is, to the solution and application of right-angled triangles, under all sorts of conditions, such as in problems of elementary surveying, the resolution of vectors, areas, solutions of triangles in general, &c, and later on additional illustrations of right-angled triangles occur in the chapter on traverse tables Four-figure mathematical tables, including logarithms, are in constant use, and careful attention is paid to arrangement and checking of the numerical work After this thorough grounding, angles of any magnitude are introduced, and triangles are solved by general formulæ, a useful table of log haversines being here provided Then the radian measure of an angle is explained, and the treatment becomes more abstract, the final chapters dealing with multiple and submultiple angles, transformation formulæ, identities, equations, and inverse notation. Finally, there are two hundred miscellaneous examples grouped in sets of five, and collected answers to the very numerous exercises distributed throughout the book The author is to be congratulated on having produced a very notable text-book on elementary trigonometry, and one that is worthy of adoption in the secondary, technical, and public schools throughout the country

(2) Messrs Lock and Child, like the author just noticed, start with the very laudable idea of presenting the subject in a more practical and less abstract form than is commonly met with, and they are successful, though not to the same extent as in the previous case Their development of the subject is not so finely graduated, they have not sufficiently recognised the fundamental importance of the right-angled triangle, and their special five-figure tables, without differences, though compact, become tedious in use and necessitate undue attention being given to the theory of proportional parts, a side issue The opening chapters of the book are geometrical, and contain descriptions of practical methods of measuring angles, both of azimuth and of elevation, a detailed description of the sextant and theodolite being reserved for a later chapter Suitable exercises and test papers are provided at intervals, and the work concludes with answers and an index The book contains many good features, and can be recommended especially to students preparing for the examination of the Board of Education in mathematics, stage 2

(3) As the result of increased experience, and also to meet the requirements of examiners, the subject-matter of Mr Andrew's well-known "Geometry" has been re-arranged and added to, while preserving the excellent features of the original work Thus the first seven chapters are mainly experimental, practical, and quantitative, and with the "intimate first-hand knowledge" of geometry thus obtained the learner is well prepared for the theoretical work of the next chapter, in which formal proofs are given, arranged in logical sequence The deductive method is employed in subsequent work, which deals with similar figures, the solution of triangles solid geometry and projection, and the mensuration of geometrical solids The plan and scope of the book are excellent, and in its revised form the manual will deservedly appeal to an increasing number of readers

(4) The "Commercial Arithmetic" by Mr Douglas is a very interesting work Assuming the student to possess a knowledge of the fundamental rules of arithmetic, the author begins with examples of the tabular arrangement of numbers, with checks labour-saving devices, and contracted and approximate methods in addition, subtraction multiplication and division, and with the decimalisation of money In the chapter on the calculation of prices we find some very neat methods of working For example, since $365=240+120+5$, we have 365 at, say, 8d each $=$ 8l + 4l + 3s 4d = 12l 3s 4d In dealing with percentages, commission, discount, and profit and loss, examples of commercial book-keeping are given, and there is the same regard for special and rapid methods of computation In the calculation of simple interest for a specified number of years and days, an ingenious method known as the "third, tenth, tenth" is much used The table given on p 88 for finding the

number of days between any two dates would be improved by a grouping of the rows. Subsequent chapters deal with compound interest, various kinds of discount, bills of exchange, shares, mixtures, and with examples involving general tables of weights and measures, English and French. Collected answers are given at the end, and altogether the book is very cleverly written, and seems eminently suited for use on the commercial side of the numerous technical and secondary schools of the country.

(5) This book is practically the authors' "Junior Arithmetic," with the chapters on the first four rules replaced by sets of examples for revision. It is intended for the middle and lower forms of secondary schools and is specially adapted to the requirements of the Oxford, Cambridge, and Scotch local examinations and the like. The explanations of the rules are condensed, and the book contains a very large collection of examples, and is printed both with and without answers.

(6) The volume by Mr. Borchardt is based on the author's "Arithmetical Types and Examples," but with many additions, the explanations and statements of the rules are left entirely to the teacher, the sets of examples being well chosen and carefully grouped. The book is suitable for use under conditions similar to those stated under No. 5.

(7) Clive's "New Shilling Arithmetic" is mainly a collection of exercises and problems, with such statements and definitions of rules as a pupil might profitably commit to memory. It covers largely the same ground as the two previous books, all three having been much influenced by the recent reforms in mathematical teaching. The book can be had with answers at a small extra cost.

(8) The "Junior Practical Mathematics" is intended for use in preparatory and public elementary schools and in the lower forms of secondary schools. The book is divided into two parts, which may be obtained either separately or together, and with or without answers. Part i. is mainly arithmetical, but the numerical work is supplemented throughout by algebraical and graphical work. This part contains, amongst other things, the four simple rules, practice, brackets, areas, volumes and weights, graphs, fractions, indices, logarithms, proportion, percentages, interest, approximations, and contracted methods. Part ii., which is chiefly geometrical, includes elementary plane geometry, orthographic projection and descriptive geometry, and some mensuration. In both parts the sequence is unusual, and seems somewhat erratic. The book is well supplied with a good variety of examples and exercises.

(9) The preface to this suggestive book is written by Mrs. Boole, who is the originator of the method described in its pages, a system which well deserves the sympathetic consideration of educational reformers. The leading idea is, working on untutored minds, to find "a means of introducing little children to the conception of a connection between organic thought-sequence and the evolution of harmonious form." The means employed is simple embroidery in coloured threads, by following some simple rule "a graceful curve such as he has perhaps never before seen or imagined, grows up under his hands, as if by miracle." One such is the curve of pursuit. The method has been successfully carried out by Mrs. Somervell and others, and has developed into a system of geometrical design which Mrs. Boole unhesitatingly believes "is a working possibility as a means of truly national evocation of creative and organising power." In order to encourage the spread of the system sets of curve-sewing apparatus have been designed, and can be procured at a moderate cost.

THE ZOOLOGIST AND SPORTSMAN IN BRITISH COLUMBIA

Camp-fires in the Canadian Rockies. By Dr. William T. Hornaday. Pp. xvii+353; illustrated. (London: T. Werner Laurie, 1906.) Price 16s. net.

MOST sporting books leave the distasteful impression that the hunter's main interest in wild animals is that they are something to kill—the bigger the better. But this book shows us a hunter who, though ardent in the chase and glowing with its barbaric excitement and triumphs, has yet a conscience in his slaying, and can, on occasion, find as keen pleasure in stalking without intent to kill, but only to observe and picture. So that while the sporting man will find in the book a sufficient spice of hunting incident and success to stir the savage emotion, the less bloodthirsty reader also will find satisfaction in the moderation of this hunter and in his vivid presentment of the wild life of mountain and forest.

The book is the record of a recreative holiday trip made in the autumn of 1905 by Dr. Hornaday, the Director of the New York Zoological Park, under the guidance of his friend Mr. Phillips, Pennsylvania State Game Commissioner, to a hunter's paradise hidden away among the mountains of the south-eastern part of British Columbia, where, actually, on the first day of their coming, a band of mountain-goats stampeded through their very camp, almost upsetting the cook at his work!

Here, and at a later camp, with the tangled forests below them and the stony peaks above, they spent their thirty days in great content, readily securing the few picked specimens of mountain-goat and sheep for which they had come, having also the additional luck to add a grizzly bear apiece to their trophies, and thereafter enjoying splendid though somewhat hazardous sport in striving, with success, to "break record" in photographing their live game at close and still closer quarters among the precipices. Of these days in the "home of the mountain-goat" two only were given to hunting goats to shoot them.

"We saw two hundred and thirty-nine individuals. . . . It was because we shot little that we saw much."

Here is a charming picture of the kind of thing they saw:—

"Rising into view out of a little depression on the farther side of the meadow, lazily sauntering along, there came ten big, snow-white billy goats!

The air was clear, the sun was shining brightly, the meadow was like dark olive-brown plush,—and how grandly those big pure-white creatures did loom up!

For more than an hour we lay flat on our pinnacle, and watched those goats. They were more than deliberate, they were almost stagnant. They were already so well fed that they merely minced at the green things around them. Each one seemed steeped and sodden in laziness. When out grazing, our giant tortoises move faster than they did on that lazy afternoon. When the leader of this band of weary Willies reached the geographical centre of the sky-meadow, about two hundred yards from us, he decided to take a sun-bath, on the most luxurious basis possible to him. Slowly he focussed his mind upon a level bench of earth, about four feet wide. It contained an old goat-bed, of loose earth, and upon this he lay down, with his back uphill. Five minutes later a little higher up the slope, another goat did the same thing, and eventually two or three others laid down. One, however, deliberately sat down on his haunches, dog-fashion, with his back uphill. For fully a quarter of an hour he sat there in profile, slowly turning his head from side to side, and gazing at the scenery while the wind blew through his whiskers" (pp. 82–4).

Mr. Phillips's photographs of the mountain-goat at close quarters, obtained at such desperate hazard, are admirable, but, after all, he cannot give us that touch of mountain breeze through the lazy Billy's whiskers! And what a pity that such a restful holiday-picture should be spoilt by the crack of a rifle!

Dr. Hornaday's first care in this volume is for the mountain-goat (he scorns the term "antelope-goat" as being affected and incorrect), and next for the mountain sheep and the grizzly bear, but he finds room also for the small neighbours of the big game—the wolverine, pine marten, coyote, pika, ground-squirrel, pack-rat, and others—all depicted with the same sympathetic and vivid touch, and generally with authoritative notes upon their geographic range and novel observations on their habits, and the birds of the region, too, receive a share of his careful notice.

The author deplores the practical extinction of wild life in the Western States, and calls upon the Canadian authorities to do what his own Government has failed to do—stringently to preserve the remnants. He considers that the British Columbian game laws err in being too liberal in every particular, and pleads for the absolute protection of all female game animals and for a reduction of the number of head allowed under each shooting license. Even the grizzly bear should, in his opinion, be protected, and he thinks that, with proper care, the Canadian Rockies might continue almost indefinitely to be the Delectable Mountains of the vigorous sportsman. The attempts that are being made toward this end should be of interest to the student of sociology, who may here watch the development of game laws anew in a democratic community.

To the splendid photographs with which the book is illustrated, and to the sensational circumstances in which some of them were obtained, we have already referred. Both astonishing and amusing is the account given by Mr. Phillips of how, during one of these operations, while on a dangerous rock-ledge from which he could not retreat, he was charged by an angry goat:—

"There was really nothing that I could do except to hold the [stereoscopic] camera at him and snap it. He charged up to within a yard of me, but with his eyes fixed on the two lenses. Then he appeared to conclude that any animal that could stand that much without winking was too much for him, so shaking his head and gritting his teeth he stopped, and to my great relief slowly backed into his niche" (p. 190).

No wonder that the resultant photograph is a "record"!

That the trip was one that any zoologist must have enjoyed goes without saying, and we thank Dr. Hornaday heartily for this delightfully written record of his own pleasure in it. Indeed, perhaps the chief charm of the book is that he manages so faithfully to convey a sense of the recrudescence of boyish energy and spirits in staid middle life, aroused under the stimulus of unusual and invigorating surroundings, for is not the enthusiasm of middle-life more contagious than that of youth itself? So let us all echo, for him, his own farewell wish:—

"May heaven keep my memory of it all as fresh as the breezes that blow on Goat Pass, as green as the pines and spruces that clothe the lower slopes of those delectable mountains"! G. W. L.

A BOOK ON CLAYS

Clays, their Occurrence, Properties, and Uses, with Especial Reference to those of the United States. By Dr. Heinrich Ries. Pp. xvi+490. Illustrated. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1906.) Price 21s. net.

"DOUBTLESS few people realise the importance of the clay working industry in the United States, and yet this is not so surprising since clay has less popular attraction than many other mineral products, such as gold, silver, &c. A casual glance, however, at the annual figures of production will probably speedily convince one that clay is to be classed among the foremost products of the country, being outranked only by coal and iron."

In 1904 the value of the clay products of the United States was 26,204,650*l.*, while the raw clay, mined and sold within the States, amounted to 464,030*l.* Not so long ago America was more backward than Europe in the attention she paid to her clay resources. This has now been changed. In recent years we have witnessed the growth of a goodly crop of literature upon this subject in the United States, both in official publications and in occasional papers. The crop has been a heavy one in more senses than one, and bulky withal, and few there are, even in America, whose shelves could afford it space. It should be therefore a matter for congratulation to all American clay-workers that for the sum of five dollars they may now obtain in convenient form—the selected fruit—that which they had already received gratis in great volume. Although the possessors of the numerous

State Reports will be familiar with the style and most of the matter of this book, it is an undoubted advantage to have the information within reasonable compass

But Dr Ries has not merely produced a condensed epitome of earlier publications, he has prepared a well-balanced, thoroughly practical work on American clays and clay-products, including a capital summary of our knowledge of the properties of clays in general The whole has been brought well up to date

The author treats his subject under the following heads —(1) The origin of clay, (2) chemical properties, (3) physical properties, (4) kinds of clay, (5) methods of mining and manufacture, (6) distribution of clay in the United States, (7) Fuller's earth

The distribution of the clays is considered under each State separately, according to the geological age of the formations, but an excellent index enables references to particular kinds of clay to be found readily

It may be remarked that we are still in the dark as to the cause of plasticity in clays, in spite of the numerous theories, nor has any generally applicable method of measuring this property been discovered Dr Ries discusses the subject with great fairness. We heartily commend his views upon the loose way in which kaolin and kaolinite are so often confused, and especially his objection to the assumption that kaolinite is the normal basis of *all* clays, a brief comparison of analyses at once dispels this idea

This book is very well produced and free from slips, but we are somewhat puzzled by the "increase in texture" mentioned on p 107

THE ÆTIOLOGY OF LEPROSY

On Leprosy and Fish Eating A Statement of Facts and Explanations By Jonathan Hutchinson F R C S, F R S Pp xxiv+420 (London Archibald Constable and Co, Ltd, 1906) Price 12s 6d net

THE object of this work is stated in the preface to be "to carry conviction to the reader that the fundamental cause of the malady known as true leprosy is the eating of fish in a state of commencing decomposition" The various districts in which leprosy occurs have been examined, and it is found that in practically all fish is consumed as an article of diet, often in a more or less stale condition, the prevalence of the disease frequently being in a direct ratio to the amount of fish eaten Mr Hutchinson would associate the former prevalence of leprosy in the British Isles and in Europe with the Roman Catholic ordinances prescribing fish-food on two out of every three week-days, its decline in these countries with the relaxation of discipline which preceded the Reformation, its extinction with the establishment of Protestantism

We think that Mr Hutchinson goes much too far in thus ascribing *all* variations in the prevalence of leprosy as being correlated with those of a fish-diet, even in the fact that the disease is more prevalent among men than among women he sees support for his hypothesis, for he suggests that women are more fastidious feeders than men, that men would be more likely than women to obtain fish if this were expensive, and so on Why fish fresh or properly salted does not convey the disease and only bad fish does is by no means clear, the single suggestion given being that there may be some connection between tuberculosis and leprosy, and that fish-diet may contain some constituent which may modify the tubercle bacillus and convert it into the leprosy bacillus! Mr Hutchinson maintains that the facts he has collected point to the conclusion that the efficient cause of leprosy must be some article of food (p 33), and that fish is the only one of universal occurrence which can be traced

But is it necessary to find a *single* mode of origin for the disease in every part of the world? Surely not, and if so there is no need to limit it to fish Mr Hutchinson admits that personal contact may convey the disease, but declares that this mode of infection is exceedingly rare, "where one had acquired the disease, hundreds equally exposed to risk had escaped" (p viii) But the latter statement proves little, all of us who live in big towns must daily come in contact with the virus of tuberculosis, yet only an unfortunate few contract the disease Similarly, as regards the decline of leprosy, most, if not all infective diseases show periods of epidemic prevalence and of decline, to what can be ascribed the disappearance of plague and of malaria from England? Mr Hutchinson says the world-wide distribution of leprosy proves that "it is not solely dependent upon contagion", this does not appear to mean personal contact, but to suggest an origin *de novo* Would not the same apply almost equally to tuberculosis, but would it be said that therefore the last-named disease is capable of "independent origination"? In the case of tuberculosis, often many years may in all probability intervene between infection and manifestation, in leprosy we do not know how long the virus may lie latent, and therefore an exposure long forgotten may really be the determining cause of the attack, without bringing in a *de novo* origin, in those rare cases in which it has not been possible to trace the source of infection

Lesions of the nasal mucous membrane are extremely frequent in lepers, and the nasal discharge may therefore be the chief vehicle by which the virus is disseminated It has also recently been reported that the mosquito and the bed-bug may harbour the bacillus, further channels again by which infection may be carried These, together with the close contact and promiscuous intercourse which exist between the members of native races, seem to us sufficient to explain the source of infection in leprosy, fish-diet being only a remarkable coincidence

In thus criticising Mr Hutchinson's theory we do not in the least desire to belittle his work, which is of the greatest interest, and his book is a valuable contribution to the epidemiology of leprosy,

OUR BOOK SHELF.

The Elements of the Science of Nutrition By Prof Graham Lusk Pp 326 (Philadelphia and London W B Saunders Co, 1906.) Price 12s net

PROF GRAHAM LUSK is to be congratulated on having produced a very interesting and important book The author is an investigator imbued with the true scientific spirit, and his work has always been characterised by thoroughness and sincerity The introductory chapter is a very lucid exposition, not only of the history of research on the subject of metabolism or nutrition, but it also gives an excellent summary of the nature of the problems to be attacked, and the main results hitherto obtained This chapter alone entitles the book to high distinction, but the subsequent chapters which fill in the details of the picture maintain the high standard of the beginning The reader will find here a mine of useful information, and will easily comprehend the facts in their relation to each other, so clearly and exhaustively are they dealt with

The English reader will be able to study for the first time in his own language the epoch-making work of Rubner, who has, among other points, directed attention to what he terms the specific dynamic value of the foodstuffs, fat outside the body is the most readily combustible of the proximate principles of food, and weight for weight yields more than twice the number of calories which proteids give rise to Fat has, of course, the same calorific value when it undergoes combustion within the body, but it is inferior to the proteins as a heat generator, because it is burnt with so great difficulty there The proteins are the most readily burnt of all the foodstuffs, and this property of stimulating metabolism constitutes their specific dynamic value In the discussion now in progress on the amount of protein food which is necessary, a question raised by the recent work of Chittenden and his colleagues, this factor is one which must not be lost sight of

The book not only deals with metabolism in health, but also in diseased conditions (gout, diabetes phosphorus poisoning, fever, &c) This makes the work very comprehensive, for it is just in these questions of nutrition that physiologists and pathologists may mutually learn so much by a correlation of their respective spheres of study In the chapter on diabetes, one notes the following sentences —

"No disease has been more thoroughly investigated In presenting the details to the reader, it may be remarked that the work done is prophetic of possible accomplishment along scientific lines in the study of disease It is typical of that scientific medicine which affrights the devoted spirits of a passing empiricism "

Prof Lusk evidently speaks with feeling, and has perhaps suffered from the passive resistance of the conservative "devoted spirits" to whom he alludes If anything will move them, it will be study of such books as the one we are dealing with

The book is very appropriately dedicated to Carl von Voit, the pioneer of such work, and the author's old master

W D H

Physical Chemistry for Electrical Engineers By J Livingston R Morgan Pp viii+230 (New York John Wiley and Sons, London Chapman and Hall, Ltd, 1906) Price 6s 6d net

THIS book has been written not only for the professional electrical engineer, but also for the use of those who desire to obtain a knowledge of physical chemistry sufficient in its scope for the understanding of current work in electrochemistry The subject-matter is divided into seven chapters, which treat respectively of fundamental principles, the general properties of gases, heat and its transformation into other forms of energy, solutions, chemical mechanics, equilibrium in electrolytes and electrochemistry An eighth chapter is devoted to a series of problems

In the method of presentation the standpoint of the now fashionable cult of "anti-atomists" has been adopted, the author's opinion being "that by placing the subject upon a purely experimental basis, giving a practical experimental definition of each concept as it is used and drawing no inference not justified in all its parts by actual results, the reader's idea will be the more clear and scientific " This is distinctly unfortunate, for nothing is gained by the non-recognition of the atomic and molecular hypotheses The services rendered by the hypothetical atom are too enormous for the concept to be discarded on purely pedantic grounds Apart from this, the detailed treatment of the subject-matter is good, and the chemical student will find the book interesting reading. It is scarcely to be expected, however, that its contents will be understood by the professional electrical engineer No doubt a knowledge of physical chemistry is essential for the engineer who would understand the working of storage batteries and the recent developments in electrochemical industry, but when the training of the electrical engineer in this country is considered, the possession of the chemical knowledge requisite for an intelligent reading of Prof Morgan's book is scarcely to be expected

H M D

The Technical College Set of Mathematical Instruments No 727 (London W H Harling) Price 2l 2s

THERE is great diversity of opinion as to the most suitable case of drawing instruments for students, many colleges having their own particular specifications, but it would be difficult to find a more desirable set of instruments than this of Mr Harling, on account both of the judgment displayed in the choice of the instruments and the design and workmanship exhibited In the neat pocket case will be found a 4-inch bow compass, with pen and pencil fittings and lengthening bar, a 5-inch hair divided, three spring bows, two drawing pens, a pricker, keys, spare leads, and needles The instruments are of the best English design and finish, with knee joints and nut and bolt needle points where necessary

A student who possesses this case of instruments is so far well equipped for his work in drawing and graphics, and gets exceedingly good value The instruments can be highly recommended as being entirely suited to their purpose

A Second German Course for Science Students By Prof H G Fiedler and F F Sandbach Pp vii+76 (London A Moring, Ltd, 1906) Price 2s 6d net

IN a former volume, favourably noticed in NATURE of May 24, 1906 (vol lxxiv, p 78), the authors described a series of simple lessons in science suitable for reading by elementary students of the German language The present volume contains extracts from recent German scientific publications—books, periodicals and proceedings of societies—of a more technical character but arranged, so far as possible, in order of difficulty Some notes on unusual words and phrases, hints on the use of a dictionary, a grammatical summary, and a list of abbreviations provide all the assistance the reader is likely to require at this stage The extracts have been carefully selected, and will be read with interest and profit by students of physics and chemistry who have a slight knowledge of German

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

One Vote, One Value

A CERTAIN class of problems do not as yet appear to be solved according to scientific rules, though they are of much importance and of frequent recurrence. Two examples will suffice. (1) A jury has to assess damages. (2) The council of a society has to fix on a sum of money, suitable for some particular purpose. Each voter, whether of the jury or of the council, has equal authority with each of his colleagues. How can the right conclusion be reached, considering that there may be as many different estimates as there are members? That conclusion is clearly *not* the *average* of all the estimates, which would give a voting power to "cranks" in proportion to their crankiness. One absurdly large or small estimate would leave a greater impress on the result than one of reasonable amount, and the more an estimate diverges from the bulk of the rest, the more influence would it exert. I wish to point out that the estimate to which least objection can be raised is the *middlemost* estimate, the number of votes that it is too high being exactly balanced by the number of votes that it is too low. Every other estimate is condemned by a majority of voters as being either too high or too low, the middlemost alone escaping this condemnation. The number of voters may be odd or even. If odd, there is one middlemost value; thus in 11 votes the middlemost is the 6th, in 99 votes the middlemost is the 50th. If the number of voters be even there are two middlemost values, the mean of which must be taken; thus in 12 votes the middlemost lies between the 6th and the 7th, in 100 votes between the 50th and the 51st. Generally, in $2n-1$ votes the middlemost is the nth, in $2n$ votes it lies between the nth and the $(n+1)$th.

I suggest that the process for a jury on their retirement should be (1) to discuss and interchange views; (2) for each juryman to write his own independent estimate on a separate slip of paper; (3) for the foreman to arrange the slips in the order of the values written on them; (4) to take the average of the 6th and 7th as the verdict, which might be finally approved as a substantive proposition. Similarly as regards the resolutions of councils, having regard to the above ($2n-1$) and $2n$ remarks.

FRANCIS GALTON.

A New Volcanic Island

THE officer in charge of the Marine Survey of India, Commander W. G. Beauchamp, R.I.M., has forwarded the following description of Volcano Island derived from an examination made about sixteen days after its appearance above water. The island is situated off the coast of Arakan, in the Bay of Bengal, about nine miles to the north-westward of Cheduba Island, and has a greatest length of 307 yards in a S.S.W. and N.N.E. direction, and a greatest breadth of 217 yards in a N.W. and S.E. direction; the summit is 19 feet above high water.

Except close to the shore the soundings in the neighbourhood appear to be unaltered, including the shoal to the N.N.W., which was touched on one line of soundings. The ship approached the island from the north-eastward, and left in an E.S.E. direction. A steam cutter left to the southward for ten miles and returned from S.S.E., and on neither course was any discrepancy in the chart discovered.

The island is still in an active condition at the northern end, several hot springs of liquid mud overflowing. It is steeper on the western side.

Temperatures (Fahrenheit) were taken at different parts of the island, the surface registering 81°, being the same as the atmosphere, at 2 feet below the surface 96°, 3 feet below surface 104°. But at the observation spot on the summit, and evidently the main crater, the temperature at 1 foot below the surface was 104°, at 2 feet below 108°, at 3 feet below 138°, and at 3½ feet the thermometer rose to 148°. No self-registering thermometer was available to take the temperature of the liquid mud. The ordinary thermometer could not be cleaned quickly enough to get an accurate reading.

The island is evidently becoming hard, but the action of the sea and tide is washing it away considerably at present, leaving a wake of discoloured water, giving the appearance of a shoal spit. The Admiralty charts show that several mud volcanoes exist in the neighbourhood.

Drift-wood, sand, and stones were found, although the island was only fifteen or sixteen days old. Fourteen kinds of seed were collected by the surgeon naturalist, from whose geological report it appears that the island is composed wholly of greyish-brown mud of uniform quality throughout; with this are a few angular fragments of rocks of various kinds intermingled. These must have been thrown up with the mud; they include:—(*a*) portions of a laminated sandstone; (*b*) a compact grey rock which has the appearance of a limestone, but which is only partially soluble in strong acids; (*c*) lumps of crystalline calcite; (*d*) a soft green stone, probably a basic igneous rock.

On December 31, 1906, the surface was sun-dried and hardened, so as readily to support the weight of a man. The dried surface is very uneven throughout; it has a nodular and bubbly appearance; besides this, it is split up by deep fissures, due to shrinkage in drying.

On the north side of the island are several small vents. Three of these open into round pools of liquid mud, to the surface of which large bubbles of gas are continually rising. This gas is non-inflammable, and does not support combustion; it has an objectionable sulphurous smell.

In regard to the permanence of this island, considering the nature of the material of which it is composed, it is likely that heavy rains and sea action in the south-west monsoon will cause rapid disintegration and total disappearance, always provided that no more material is erupted.

The following case may be quoted from Lyell's "Principles of Geology," vol. ii.:—In 1811 the Isle of Sabrina was formed off the Azores by submarine volcanic action. This, although 300 feet high, "was soon washed away by the waves."

Hydrographic Department, Admiralty, London, S.W.

The Forest-pig of Central Africa

As will be remembered, the singular and interesting forest-pig *Hylochoerus meinertzhageni*, which appears to be an intermediate link between the true Sus and the aberrant Phacochœrus, was first mentioned and named by my friend Mr. Oldfield Thomas in these pages (NATURE, vol. lxx., p. 577, 1904). I believe, therefore, that some further information which widens considerably its range may prove of interest to readers of NATURE.

The type of this remarkable pig is the cranium of a nearly adult male from the Nandi country (F.N.E. of the Victoria Nyanza), sent home by Lieut. R. Meinertzhagen, and now in the British Museum; this, with parts of the skulls of an older male specimen and of a sow, with portions of the skin covered with long black hair of the first, are the materials on which Mr. O. Thomas has described this species (Proc. Zool. Soc. London, 1904, ii., p. 193, pl. xiv., xv.). Since then further materials have been received by the British Museum, also the skull of what appears to be a second species (Proc. Zool. Soc. London, 1906, p. 2).

The Royal Zoological Museum of Florence received a few months ago from Lieut. Ernesto Brissoni, an officer in the service of the Congo Free State, a perfect cranium of a large full-grown male of *H. meinertzhageni*, shot by him at Sendue, on the Upper Congo River, where he was stationed for many months in November, 1904. It is a remarkably big and massive skull, as will be seen by the principal measurements, which, to facilitate comparison, I give in the same order as those taken on the type-specimen by Mr. Thomas; they are in millimetres:—greatest median length, above 425; basal length, 360; zygomatic breadth, 250; nasals, length 260, breadth 70; interorbital breadth, 123; tip to tip of post-orbital processes, 155; intertemporal breadth, 98; breadth across

lateral occipital protuberances, 140, height from basion to top of occipital crest, 137, least breadth maxillary zygomatic process, 70, breadth across sockets of canines, 70, breadth across tips of canines, 290, length of palate, 270, least palatal breadth, between m^2, 40, basal diameter of canine, 40, lower jaw, length, bone only, 325, breadth across symphysis at base of canines, 130, least breadth across diastema, 105, height at diastema, 55, tip to tip of canines, 225 basal diameter, outer face of canines, 22, inner face, 24, posterior face, 16, horizontal length of p^4, 15, of m^1, 19, of m^2, 26·5, of m^3, 45

Dental formula $i\,\frac{3}{3}\,c\,\frac{1}{1}\,p\,\frac{4}{4}\,m\,\frac{2}{3}$

As I have said, this cranium is massive, the bones rugose on their outer surface, the nasals mostly fused together, and the frontal depression strongly marked

Gambling and Mathematics

YOUR reviewer "G H B" suggested in NATURE of January 31 (p 318) that every schoolboy should know something about choice and chance in order that he may not develop into a gambler I agree with him But one may suspect that gamblers are either those who have not had the advantages of a mathematical education or those who belong to 'slow dull' grade and are unable to appreciate those advantages, and yet one may be quite unable to prove that this is really the case

Can any of your correspondents bring forward evidence to show that mathematicians gamble less than other men, or that gamblers really are mathematically defective?

The matter is important as indicating the point at which the efforts of an anti-gambling league should be most usefully applied Is it in the intelligent teaching of mathematics? And are we right in distrusting the methods of exhortation when the methods of algebra will suffice?

Bootham School, York HUGH RICHARDSON

THE subject of Mr Richardson's letter raises a wide field of discussion, of which the few words in my notice convey a very imperfect idea I should like to see the matter discussed in a suitable quarter when such can be found, but I believe it is a question for psychologists as well as mathematicians

I take it that the ordinary gambler speculates in order to *win*, and that the prospect of *winning* is the incentive which does the greatest harm

When a man speculates by staking, say, 1*l* on the chance of winning 100*l*, the notion of winning 100*l* makes a big impression on his mind, and means something more real to him than the idea that the odds are 200 to 1 against him (say) He forms a clear mental picture of the prize, and the odds do not present the same picture to his mind Consequently he exaggerates his prospects What I meant to imply is that schoolboys ought to learn to calculate probabilities so that when they grow up they should think as clearly and form as strong mental pictures of the odds against them in a game of chance as they do of the value of the prizes, and that they should learn to calculate expectations and to think of these rather than of the prizes

But when Mr Richardson uses the word "algebra" he implies something different from what I mean, which is more correctly described as arithmetic What I should like would be to see a chapter on probabilities treated in an elementary course of arithmetic, and boys familiarised with the idea of probability calculations, the representation of probabilities by fractions, and the calculation of expectations, without any algebra being put in to puzzle them Quite simple questions, in fact I will not say that everyone who had studied probabilities would not indulge in a game of chance now and then but they would go in with the expectation of losing rather than winning, and they would know it was no use to try to make up a loss by making false estimates of the probability of the luck turning If nobody gambled except for the amusement and if everybody before doing so made a calculation beforehand as to how much they were prepared to pay for that amusement, realising that their expectation in every case was a loss (if playing against a bank), the worst evil of gambling would be eliminated The only difficulty would be the psychological one of preventing a man from being carried away by his excitement

What people should know is that to speculate against a bank or syndicate is a bad investment, and that even to speculate where all profits are distributed between players is not a paying investment, but is really also a bad investment even if the expectation equals the man's stake, on the ground that a bird in the hand is worth two in the bush The loss of the bird in the hand means a definite loss of income, the expectation cannot be regarded as income G H B

Some New Methods in Meteorology

SINCE the appearance in NATURE of December 20, 1906, of my review of Prof Bigelow's "Studies" under the above title, I have had some correspondence with Prof Willis L Moore chief of the U S Weather Bureau I am glad, with Prof Willis Moore's sanction, to quote part of his letters to me, which will, I hope, allay any apprehensions which may have been aroused as to the methods of research likely to be adopted at the new Mount Weather Observatory Prof Moore writes —" Since June, 1905, Prof William J Humphreys of Johns Hopkins University, and formerly Professor of Physics at the University of Virginia, has been Supervising Director at our institution at Mt Weather We wish to ascertain facts by experimentation, rather than to exploit theories, however beautiful they may be We consider Prof Bigelow's numerous papers as expressing simply his own views Neither myself nor any member of my staff desires to be considered responsible for any theories that may be advanced in the publications of the Bureau, except he be the author "

Prof Willis Moore's explanation, and his recognition of *experiment as the necessary and ultimate criterion*, justify the expectation that, backed as it is by the resources of the U S Weather Bureau, the new research observatory at Mount Weather will prove a most useful institution for the advancement of scientific meteorology

CHARLES CHREE

PAGAN RACES OF THE MALAY PENINSULA [1]

THE scope of this work, which runs to nearly 1600 pages is defined in the preface, where it is stated to be "essentially a compilation from many sources," but differing from most books of that kind, "first, in being based to a very large extent on materials hitherto unpublished, and accessible only through private channels of information, and secondly in having been constructed with special knowledge of the subject and in a critical spirit"

Accurate though these statements be, they offer but slight indication of how thoroughly the book is inspired with the experience and critical knowledge of the authors, and how well the subjects dealt with have been unified in their hands, a task the difficulty of which may be judged in part by a consideration of the unsatisfactory nature of much that has been written as well as by the length of the bibliography which follows the preface The authors explain that the several parts of the book dealing with the physical and cultural characteristics of the tribes had been originally arranged under subject headings, and that the book was then re-written upon "a phylogenetic system, so as to throw into relief the differences which separate one race from another," a plan which no one will doubt has added immensely to the clarity of the work Although the title-page bears the name of both authors, the greater part of the work has been written by Mr Skeat, Mr Blagden

1 "Pagan Races of the Malay Peninsula By W W Skeat and C O Blagden Vol I, pp xl+724, vol II pp xi+855 (London Macmillan and Co., Ltd, 1906.) Price 42s net

being responsible only for the section dealing with language, although each author has "as far as possible revised and checked the work of the other."

An introduction in which Mr. Skeat sketches with great skill and literary force the environment of the jungle-dwelling folk shows how this has produced characteristic forms of culture, and has compelled the jungle tribes to become perhaps the finest hunters and trappers in Asia. This is succeeded by the first section of the work, that on racial characters, and here, at the very beginning of the work, the reader is faced by its gravest defect; in the whole of the first volume there is no map of the Peninsula, the necessity for which soon becomes manifest and is most urgently felt, *e.g.* on p. 55, where the distribution of the Sakai is given. Indeed, the only map of the Peninsula appears at the end of vol. ii., where it forms part of a small-scale map of Indo-China (about two degrees to the inch), which includes the Andamans, Sumatra, Cambodia, and part of Siam. But to return to the discussion of racial affinities, Mr. Skeat will have nothing to do with the pan-negrito beliefs of some of the earlier writers, but leaves it doubtful whether he follows Virchow in regarding the Sakai as Dravidian or as related to certain of the wild tribes of the interior of Cambodia with whose language the Sakai dialects have an admitted affinity. The Jakun are regarded as a composite group of principally aboriginal-Malay tribes, many of which have intermarried freely with Semang and Sakai. It is only necessary to look through the numerous illustrations of individuals or groups, posed so as to show their physical characteristics, contained in these volumes to see how freely the jungle races have in certain instances mixed with each other, and the results of such intermarriage are shown, *e.g.*, in a photograph of a Sakai family the individual members of which, to mention only one physical character, have wavy, curly, and tightly coiled, almost frizzly hair. A number of valuable data bearing upon questions of race are given in tabular form in an appendix; some of these are by Dr. W. L. H. Duckworth, who also contributes a note in the text upon the craniological collection made by Messrs. Annandale and Robinson.

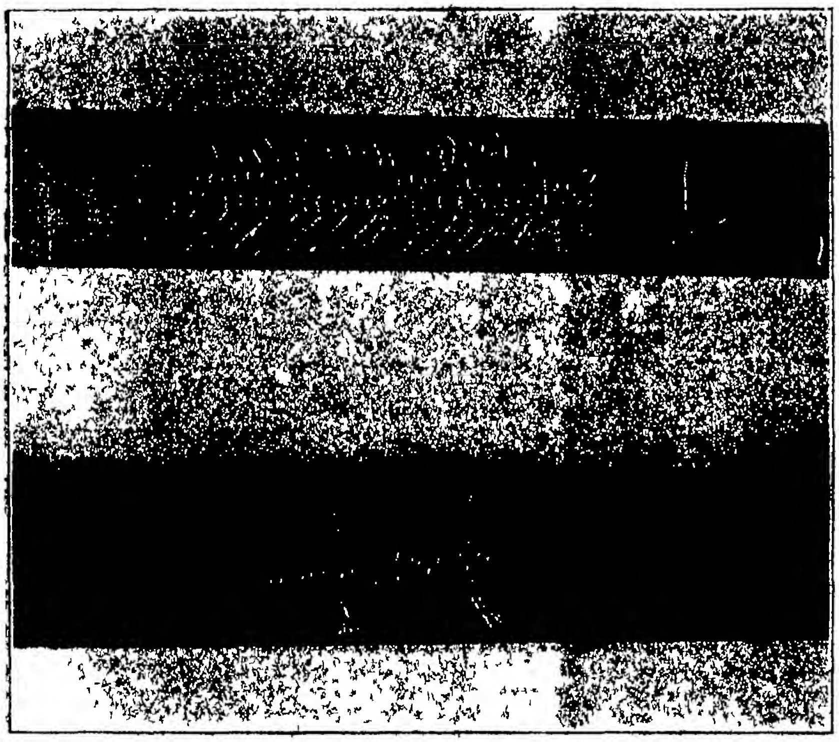

FIG. 1.—Besisi Zoomorphs. Centipede on Besisi flute; Lizard on shaft of Besisi blowpipe. From "Pagan Races of the Malay Peninsula."

A short *précis* of the distinguishing cultural peculiarities of the jungle people most usefully follows the description of their physical peculiarities. The Semang are the most nomadic, the wilder tribes "never staying it is alleged more than three days in one place", their habitations consist of natural shelters under overhanging rocks or of the simplest form of leaf shelters. Their national weapon is the bow with poisoned arrows, though the blow-pipe has been to some extent adopted; they are monogamous, and feel no such fear of the ghosts of their dead as do the Sakai and Jakun. The Sakai, though largely nomadic, are less wild than the Semang, and, unlike the latter, tattoo the face, while body painting has been developed into a regular system. Their weapon is the blow-pipe, with poisoned darts. The Jakun are only partially nomadic, and usually cultivate rice, sugar, or other plants, especially durian trees; they make and use dug-out canoes and the blow-pipe. They have chiefs, who in some cases have regalia, their marriage and burial rites are peculiar, and they have many magic ceremonies and invocations, in other words, their culture is "proto-Malay."

The habitations of these jungle tribes, which are discussed in chapter iii., are particularly intersting. Starting with shallow rock shelters and the buttresses of trees, the series passes through the "primitive bee-hive" or round hut composed of a number of palm leaves thrust into the ground in a circle, and is continued through the communal shelter (which is originally only an oval "beehive") until a break occurs, and a hut, originally probably a small granary or storehouse on one or more high posts, is reached, which, as the height and stoutness of the posts become reduced, tends to conform with the common Malayan hut type. In this series no mention has been made of tree houses, though Semang and Sakai alike make use of these, which may vary from a few roughly interwoven boughs to veritable houses in trees.

The houses of the less wild Jakun resemble in a general way those of the Malays, but are much smaller than the latter, while the eaves are often carried down to the level of the floor. It is among these people that tribal halls, called balai by both Malay and Jakun, first appear, and Mr. Skeat describes how some Besisi met with on the Selangor coast built a balai at right angles to, and in continuity with, the house of their tribal chief (Batin). Such

Sakai are mentioned in Besisi songs, and Mr Skeat holds that their existence is not due to borrowing from the Malays, but is "rather an example of a custom sprung from their common origin."

Closely associated with the character of their dwellings is the form of agriculture of these backward people. A Malay chief of Selangor informed Mr Skeat that the Besisi were originally in the habit of eating their jungle fruits in temporary shelters built where the fruit trees were most abundant, but that later, recognising that this practice resulted in overcrowding of the fruit trees which sprang from their rejected seeds, these folk took to carrying their fruit to a little distance before eating it, so as to spread the seeds over as wide an area of country as possible It must be remembered that all these aborigines are adepts at tree-felling, and there seems no doubt that fruit seeds or seedlings of fruit-bearing plants may be planted by the wilder tribes, who do not eat rice or any grain, except when they obtain a small supply by barter Those Semang who have reached an early stage of agriculture sow a species of millet Hill rice comes later, but while the folk are still semi-nomadic, and to it is added small catch-crops such as bananas, tapioca, and sweet potatoes, and among the Sakai who have reached this stage of agriculture the preparation of the ground and the sowing and harvesting of the crops are alike accompanied by magic ceremonies and formulæ

A full description of the weapons and implements at present used provides Mr Skeat with the opportunity of discussing the origin of the stone adze blades found all over the Malay Peninsula Unlike the up-country folk of Borneo, who highly value these and hang them in the verandahs of their houses among the skulls they have collected, the Semang and Sakai pay no attention to them, and it seems that these tribes "were not the manufacturers of the stone axes and chisels found in the Peninsula," which may perhaps be attributed to a race described by the jungle folk as once inhabiting their country, though different from themselves and the Malays

Among all the jungle tribes of the peninsula, the marriage rite consists largely of a form of purchase, usually followed by the ritual sharing and eating of food by bride and bridegroom, but among some Jakun tribes a part of the marriage ceremony consists of a procession or race by the bride and bridegroom around a specially erected mound, while among the Benua of Johor a canoe race, in which the bride is given a considerable start, is substituted

No less than a hundred pages are devoted to the subject of decorative art, *i e* to the art of the Semang and Sakai, described by Mr Skeat as "by far the most difficult of the many difficult subjects that have had to be faced in compiling the description of these tribes," for it is necessary "to face the fact that with reference to part of this subject an edifice has already been reared upon a foundation of sand, and that though the bricks of which it was composed may to some extent be useful in laying the foundation of the new building, the original edifice is none the less inevitably doomed to irremediable destruction." This, of course, refers to Vaughan-Stevens's flower theory, and in spite of the no less generous than skilful editing and pruning to which the latter's work has been subjected, it is impossible to believe that Mr. Skeat would not have done better to have omitted by far the greater part of his account of Vaughan-Stevens's work, and this notwithstanding the writer's very hearty recognition that no one is so fit as Mr Skeat to determine the value of Vaughan-Stevens's observations The feeling that Mr. Skeat's modesty and desire to give the fullest credit to other workers have for once run away with much of his critical faculty becomes stronger as the chapter is studied, and ends in the quite deliberate conviction that it was a mistake to reproduce pages of the patterns on combs copied from the *Zeitschrift für Ethnologie*, while the decorated dart quivers, combs, and boxes collected by Mr Skeat himself are reproduced on so small a scale that it is impossible in most instances to see the designs at all clearly. Further, although the meaning of some of these is given on p 419, it is by no means clear to which objects these refer, or whether pp 416–8 are in fact descriptions, as they appear to be, of the quivers figured in the plate facing p 414 Very little indeed is known about Jakun art The two realistic zoomorphs shown in Fig 1, representing a centipede and a lizard, occur on a Besisi flute and blow-pipe respectively, while two highly conventionalised patterns, said to be derived from the young shoot of plants, are also given

The difficulty of obtaining information concerning the religious beliefs of these jungle-dwelling tribes was very great, it was only after many conversations with both eastern and western Semang concerning the existence of any supreme being, of whom they long professed entire ignorance, that one of them exclaimed, "Now we will really tell you all we know," and proceeded to tell Mr Skeat about Ta Ponn, a powerful and benevolent, if otiose, deity, who made the world and who was "like a Malay Raja" in that "there was nobody above him" Although Ta Ponn is obviously identical with Vaughan-Stevens's "Tappern," nothing could be discovered concerning Vaughan-Stevens's superior deities of the Semang called by him Kari and Ple, although Mr. Skeat witnessed a "blood-throwing" ceremony among the eastern Semang resembling that by which, according to Vaughan-Stevens, Ple was appeased. As already stated, the Semang have little fear of ghosts, and their religion shows comparatively few traces of demon-worship and animism The Sakai beliefs, on the other hand, although admitting a "god" Tuhan (or Peng), who in company with the giantess "Granny Long-breasts" inhabits the upper heavens, are almost entirely animistic, as are those of the Jakun, and for both peoples there are numerous demons to be propitiated

It is particularly interesting to note that the two savage races of the peninsula that stand furthest apart, namely, the Semang and the Jakun, both have the idea that man at first multiplied so fast as to overcrowd the earth When this occurred they were slain by the fiery breath of the Thunder Spirit (Semang) or turned into trees by the "high" god Tuhan Di-bawah (Jakun) but in both stories these checks do not suffice, and so death is instituted, and Mr Skeat again suggests that such common features are mainly due to the "same savage Malay element of which there are such abundant traces in the dialects of both races"

As among Malays, so among these jungle tribes, the accredited intermediary between men and spirits is the medicine man or sorcerer Among the Semang he is usually the chief, that is to say, the poyang is, by virtue of his office, chief Among Sakai and Jakun the offices are sometimes separated, though the chief is usually a medicine man of some repute

In the last part of the work, devoted to the language of the jungle folk, Mr Blagden points out that most aboriginal dialects have been for some generations in a process of decay, and that Malay is so widely known as to have become the *lingua franca* of the peninsula, so that many of the aboriginals are now bilingual, while others speak

only Malay, more or less modified according to the national idiosyncrasies of the speaker. Moreover, many of the Malayan loan-words are pronounced, not as the Malays of the peninsula pronounce them to-day, but as it would seem they were pronounced when Malay was first written in Arabic characters, thus, the *k* still pronounced in Borneo also occurs in the aboriginal dialects. Besides unidentified elements, many constituents of both Semang and Sakai dialects agree with the Mon-Khmer languages, but whether this similarity be due to all these languages being essentially members of one family or to the direct contact of Semang and Sakai with Mon-Khmer peoples is uncertain, though, of course the two views do not necessarily exclude each other. There is a most interesting chapter on tabu language and other special forms of speech, and the work concludes with a comparative vocabulary of the aboriginal dialects, which is so arranged as to be particularly easy to use. C. G. S.

ELECTRIC POWER IN LONDON

UNTIL a couple of years ago the problem of electricity supply in London was mainly one of interest to engineers and investors. Its introduction into the realm of municipal politics, however, has given it a wider interest, and one that tends to obscure the purely scientific aspect of the problem. Alike in connection with water, with gas, and with electricity, London has suffered from the fact of its slow growth and of its being composed of a number of separate towns and districts, its very magnitude, which to-day would enable it to be supplied with electricity more cheaply than any other great city, has been the chief hindrance to its getting such a supply. The enormous number of authorities authorised to supply electricity in Greater London, which at the present time exceeds seventy, has resulted in the establishment of nearly sixty generating stations, many of which are of comparatively small size and inefficient design. The municipal authorities have also been confined to their own boundaries and compelled to choose uneconomical sites, and any attempts at combination between the various authorities which might have enabled them to secure some of the advantages of production on a larger scale have been prevented by the restrictive legislation under which they operate, legislation which was originally passed before the future developments of electricity production were appreciated, while the still more remarkable developments in the uses of electric power were entirely unforeseen. An attempt at concentration was long ago made by the London Electric Supply Corporation, which established its great station at Deptford. That it was not successful was not due to any unsoundness of the principle upon which it was based, but to the fact that it was before its time. Fifteen years afterwards, in 1905, a fresh proposal embodying the first step in the policy of concentration was brought forward by a private company, several of the existing companies at the same time brought forward proposals, not for complete concentration, but for dividing London into three areas, in each of which a supply would be ultimately centralised.

The former scheme, due to its novelty and comprehensive nature, aroused considerable controversy. It was framed on the lines of the various Power Acts which Parliament has passed during the past five years. That is to say, it did not deal with retail supply of *lighting*, but only authorised wholesale supply of electricity and the retail supply of *power* in cases where the Board of Trade thought such supply should be given. Its main object was the establishment of two stations, in which generation would take place on a scale much larger than that of any station in London to-day, and from which electricity would be supplied wholesale to the various distributing authorities by whom it would be retailed to the consumer. The limited right to supply the power consumer direct, in certain cases, was inserted by Parliament in order to ensure that the distributor should not absorb all the advantages of wholesale production.

This scheme naturally aroused much opposition from the existing authorities, both municipal and company. To a large extent, however, this disappeared as the real nature of the Bill became known, in fact, practically all the leading companies, and many of the most business-like local authorities, appreciating the advantages of purchasing a bulk supply in place of having constantly to expend further capital on extending their own smaller generating stations, entered into agreements with the promoters. The manufacturing interests of London also supported the scheme very warmly, and a deputation of leading manufacturers waited upon the Board of Trade, and showed that if the East End could obtain power at the prices fixed by the Bill it would mean an annual saving of nearly 3,000,000*l* as compared with the present methods of power production. A petition, signed by employers of 100,000 hands, was also presented to Parliament in favour of the scheme.

It was, however, strongly opposed by the London County Council, which, in spite of numerous modifications and safeguards, such as the sliding scale of price and dividend, and the purchase clause, which were inserted in the Bill by Parliament, contended that it was not in the public interest that such a scheme should become law. It, however, passed Committees of both Houses, but so late in the session that it failed to become law.

In the next session of Parliament, 1906, the County Council itself introduced a scheme. The 1905 company's Bill was also re-introduced, and a new scheme was brought forward by the existing companies for linking up their systems and removing the restrictions upon mutual supply to which reference has already been made. The County Council's scheme alone received a second reading, and was sent to a special Hybrid Committee with instructions to consider the whole question.

The County Council's scheme dealt with wholesale supply only, it was strongly criticised by the Council's own Finance Committee, and unanimously rejected by the House of Commons Committee which had been instructed specially to consider it. The Report of that Committee recommended, however, that the Council should be made the controlling authority for electricity supply, but as regards the carrying out of the undertaking suggested that the Council should consider cooperation with private enterprise.

This year the Council has brought forward a more comprehensive scheme, involving nothing less than a monopoly of electricity supply for all purposes over 450 square miles, 330 of which are outside the county. Fourteen of the borough council undertakings are to be compulsorily acquired within five years, the thirteen company undertakings as their concessions lapse. Undertakings outside the county of London are to be acquired by agreement, but until it has secured this monopoly, and to assist in securing it, the Council takes powers to compete (for power supply only) with all these undertakings.

From a scientific point of view the principle of concentration would appear to be correct, but whether electricity supply has reached a state of development when such a big step forward as that proposed by

the Council would be wise is somewhat doubtful There is no engineering impossibility in wiping out all the existing generating stations with their various systems of supply and in producing the whole of the electricity required for London in a station erected at Barking or Erith, as the Council proposes But from the financial point of view the magnitude of the scheme appears to be its chief difficulty Seventeen millions have already been sunk in electricity supply in London, and, according to a careful estimate in a leading financial journal, this sum would have to be nearly doubled before the Council could secure the monopoly at which it aims Before embarking upon such a scheme, from which when once started there is no turning back, the ratepayers need to be very sure of the future developments of electricity Three times in the past twenty years have the prime movers used for electrical production been entirely changed The slow-speed horizontal engines which had been developed during the nineteenth century were first used, and gave place during the 'eighties to high-speed engines of the single-acting or forced-lubricating type for electrical supply These are now being replaced by steam turbines Many inventors are, however at work upon the improvement of large gas engines and other internal-combustion machines, and the attempts which have been made to construct a satisfactory internal-combustion turbine may any day bear fruit

Now it is obvious that if electricity production in London should become municipalised, so far as London is concerned the rate of development and the adoption of improved methods will be much hindered Experience has shown that local authorities are, as in fact they should be, very cautious in adopting scientific improvements This partly arises from a proper regard for the ratepayers' money, but partly from their objection to acknowledge that they have made a mistake and to the consequent criticism of the electorate

This being so, it would be most unfortunate if anything should be done that would hinder the progress of electrical developments in the metropolis London is so large that it could certainly afford to get the best in the first instance, the difficulty is to ensure a continuance in the adoption of the most efficient methods when concerns are municipalised To day the generating station erected by the Council at Greenwich is practically obsolete as an up-to-date power house

The problem is one, however, crying for solution The need for some improvement in London electrical supply is generally admitted, as are the advantages arising from concentration The best solution of the difficulty is probably that outlined in the report of the Council's Finance Committee issued in December, which closed with the following words —

"The financial difficulties to which we have called the attention of the Council would to a large extent be obviated if the Council saw its way to adopt some scheme of exercising the powers sought, if and when conferred by Parliament, by which the Council, while retaining general control, would be relieved of the responsibility of working the undertaking in whole or in part"

Whether the solution will be brought about by enlarging the existing stations as their owners propose, or by erecting new and larger stations on more convenient sites outside, as other experts desire, is a question which must be settled by a Parliamentary Committee and the Board of Trade But more delay in concentration will be fatal to London's industrial future, and is quite unnecessary if only the Council will realise the need for cooperating with private enterprise, as the Select Committee suggested

PROF HENRI MOISSAN [1]

It was with deep sorrow that the scientific world learnt of the death of the illustrious French chemist Henri Moissan, which occurred on Wednesday, February 20, following an operation for appendicitis

Born in Paris on September 28, 1852, Moissan early developed an interest in chemistry, and in 1872 entered the laboratory of Fremy at the Muséum d'Histoire naturelle, attending also the courses of Henri Sainte-Claire Deville, Debray, and others

This early training firmly fixed the direction of his life's work, for it is precisely along the lines so ably developed by this brilliant school of French chemists that Moissan's genius and resource in experimentation were applied Worthily to have upheld the traditions and high quality of this school and to have widened the field of inorganic chemistry required powers of no mean order

From 1873 to 1879 Moissan held the post of assistant in the laboratory of MM Decaisne and Dehérain at the Muséum d'Histoire naturelle, and in 1874 published, in conjunction with M Dehérain, his first contribution to science, a study of the absorption of oxygen and emission of carbonic acid by plants kept in a darkened room In 1877 a series of papers on the oxides of the metals of the iron group was commenced the whole work being collected and presented in 1880 as a thesis for the degree of *Docteur ès sciences* of the Faculty of Sciences of the Paris University This research, carried out with much experimental skill and precision, considerably extended our knowledge of the reduction products of the oxides of iron, manganese, nickel, and chromium

A long connection with the École supérieure de Pharmacie commenced in 1879, by his appointment as demonstrator in chemistry; the chair of toxicology being given him in 1887, after his memorable isolation of fluorine, and finally the professorship of *chimie minérale* in 1899, when his first opportunity occurred for holding a course of lectures on chemistry

After his graduation, Moissan, from 1879 to 1883 devoted himself chiefly to the study of the compounds of chromium, investigating in particular the chromous salts and perchromic acid Subsequently, in the laboratory of Debray, and with the active encouragement of Troost and Friedel, he commenced his researches upon fluorine which culminated in 1886 in the isolation of this element

The difficulties, which had baffled the experimental ability of Humphry Davy, Faraday, Fremy, and many others, were overcome and fluorine itself was presented to us That this may justly be considered to be one of the greatest achievements of experimental chemistry in the nineteenth century can be judged not so much by the brilliant result attained as by the display of indomitable pluck and perseverance which assured the successful issue

After a number of fruitless but well-planned attempts to separate the element from its compounds with silicon, phosphorus and arsenic, Moissan, on June 28, 1886, communicated to the Academy of Sciences the first details of his experiments on the electrolysis of anhydrous hydrofluoric acid containing potassium bifluoride The definite proofs of the identity and elementary nature of fluorine were presented in the following month, whilst, on November 8, Debray reported to the Academy the complete conviction of the section of chemistry in the validity of the experiments

From 1886 to 1891 Moissan published numerous

[1] See also the article on Moissan's laboratory and his work in it in NATURE, January 16, 1902, vol lxv p 252

papers on the chemical and physical properties of fluorine and on many of its compounds, the careful and detailed nature of the investigations being characteristic of all his work

It is unnecessary to describe further these researches, since the whole subject forms a chapter of their science well known to all chemists, and has, moreover, already been fully dealt with in NATURE (vol xxxvii, p 179, vol xliv, p 622) Attention should, however, be directed to the fact that in 1897, in conjunction with Sir James Dewar, fluorine was liquefied at the Royal Institution The construction of an apparatus of copper in 1899, to replace the expensive platinum vessels previously employed, simplified the preparation of the element, and the discovery that dry fluorine exempt from vapours of hydrofluoric acid does not attack glass served in recent years to facilitate the investigation of its properties

In 1891 Moissan was elected a member of the Academy of Sciences to fill the chair left vacant by the death of Cahours

The main reason which impelled Moissan to pass from the study of fluorine to the high-temperature researches, which from 1892 onwards absorbed so much of his attention, seems to be closely connected with a desire, which he had long entertained, to solve the mystery of the origin of the diamond The hope that the great activity of fluorine for other elements would help in the quest not being realised, he was led to a methodical study of the behaviour and transformation of the three allotropic modifications of carbon This study, which is an excellent example of the logical application of experiment, resulted in the artificial production of diamond, and at the same time added greatly to our knowledge of the peculiar metamorphoses which characterise this element

The examination of portions of the meteorite from the Cañon Diablo proved the presence of small diamonds, surrounded by thin ribbon-like strips of compressed carbon, hidden in the centre of a mass of iron, and gave him the clue to the solution of the problem How he planned and successfully carried through the adaptation of this idea in the laboratory with the production of minute but unmistakable diamonds is well known to all Although this work has been frequently challenged, he had fully upheld the validity of the results, so recently as 1905, by repeating the experiments with still greater precautions, and by applying a more intimate knowledge of the compounds formed under similar conditions It was for the purpose of augmenting the solubility of carbon in iron that he first required and adopted the electric furnace

In electric furnace work, Moissan's preeminent position is due, not to the design or discovery of a special form of furnace, but rather to the skill with which he investigated in detail a number of individual chemical reactions In each case he devoted great care to the purification and analysis of the raw materials required in the process, and submitted the products to minute examination and quantitatively determined their composition Thus his preparation of chromium, tungsten, molybdenum, uranium, titanium, and many other metals in a fused form and high degree of purity greatly enriched our knowledge of the chemical and physical properties of these elements

Of still greater importance was the methodical following up of the chance formation of calcium carbide which he observed around the carbon electrodes in his early furnace experiments From this observation he was led to discover and determine fully the nature and properties of a large number of metallic carbides, borides, and silicides, most of them hitherto absolutely unknown, or, like the metals mentioned already, only obtainable as impure and fragmentary specimens

There is perhaps no need to consider, at the present time, in how far industry is directly indebted to Moissan's work He himself had invariably expressed his desire not to be considered in such discussions, and, so far as the merit of his work is concerned, it needs no support of this nature Indirectly, both science and industry have benefited enormously. On the Continent his scientific investigations are directly credited with a renaissance in the study of inorganic chemistry, which, particularly in Germany, had been almost entirely neglected for the more productive field of organic chemical research Even in England, which has always held a high position in the pursuit of inorganic chemistry, his work has been of great assistance in instilling enthusiasm and encouraging the deeper study of the subject

As a teacher, Moissan will be affectionately remembered by all his pupils; even during the tenure of his professorship of toxicology he maintained a research laboratory for chemistry, and attracted to it a number of students, and from the time of his appointment, in 1900, to the chair of inorganic chemistry at the Sorbonne larger numbers were able to avail themselves of his teaching

As a lecturer, both in his public discourses and in the lectures on inorganic chemistry, which he gave during the last few years of his life, he was distinguished, even amongst French chemists, by the brilliant exposition of his subject and by his skill in experimental demonstration R S HUTTON

NOTES

WE regret to see the announcement of the death of Mr H C Russell, C M G, F R S, Government astronomer of New South Wales

THE autumn meeting of the Iron and Steel Institute will be held in Vienna on September 23–25, and will be followed by excursions to Bohemia and to Styria

THE Women's Agricultural and Horticultural International Union is organising an exhibition and sale of farm and garden produce, &c, to be held in the Gardens of the Royal Botanic Society Regent's Park, N W, on Wednesday, July 17

THE Mercers' Company has made a grant of 1000*l* to the Imperial Institute for scientific research in regard to the economic products of British colonies and protectorates, to be expended under the direction of the managing committee, subject to the control of the Secretary of State for the Colonies

THE Friday evening discourse at the Royal Institution on March 8 will be delivered by Prof David James Hamilton, on "Certain Seasonal Diseases in the Sheep and means of preventing them"

ENGLISH geologists who know anything of France and the French Alps will especially regret the death of M Marcel Bertrand, which took place on February 13. His work on mountain-origins and mountain-structure had an important influence in the development of geological thought Bertrand succeeded Pasteur as a member of the French Academy of Sciences in 1896.

WE learn from the *Times* that the Royal Academy of Sciences at Stockholm is petitioning the Swedish Government to request the British Government to grant per-

mission for the removal of the remains of Emanuel Swedenborg from the Swedish Church, Princes Square, Ratcliff Highway, to Stockholm in order that they may be re-interred there by the side of the remains of the celebrated chemist, Berzelius

In the House of Commons on Tuesday, the Secretary of State for War was asked "whether he was aware that the Army Medical Department and the entire medical profession in this country were mainly dependent on foreign manufacturers for the supply of tubes for X-ray examinations" In reply Mr Haldane said —"The X-ray tubes required for military hospitals are purchased from contractors in this country who obtain many of their supplies from Continental manufacturers The few glass-blowers in this country who make X-ray tubes are unable at the present time to produce tubes in sufficient number to meet the demand or to equal in quality and price those manufactured abroad"

The Royal Academy of Sciences of Turin has announced the conditions under which the Vallauri prizes will be awarded One prize of 28,000 francs is offered to the Italian or foreign man of science who, between January 1, 1907, and December 31, 1910, publishes the most important work in the domain of the physical sciences, using the expression in the widest sense

Dr H M Birdwood whose death on February 21 has been received with regret, followed the example of his brother, Sir George Birdwood by using his botanical and horticultural interests for the public benefit while officially connected with India He was the author of a "Catalogue of the Flora of Matheran and Mahableshwar," two of the Bombay hill stations, and was a syndic of the Bombay University

An article in the *Times* of February 22 urges that the Explosives Research Committee is culpably responsible for the violent explosion at Woolwich a few weeks ago The explosion totally annihilated the magazine in which it occurred, wrecked a large number of houses in the vicinity, caused minor damages over a wide area, and produced a shock which was felt thirty miles away It is said that the research laboratory was improperly used for storing large quantities of dangerous compounds which ought not to have been near a place where experiments with explosives of unknown properties are carried on A letter signed "Scrutator" in the *Times* of February 12 states that the laboratory contained shells filled with condensed phosphuretted hydrogen and a gasometer full of this gas, and the article on February 22 asks, "what has become of the two kilograms of iodide of nitrogen the existence of which is common knowledge?" The suggestion that the explosion was due to recklessness and negligence in the research department at Woolwich is damaging to scientific interests, and it is to be hoped that the research board will afford the information required without delay

The council of the Society of Arts is prepared to award under the terms of the Benjamin Shaw trust, a gold medal, or a prize of 20*l*, "for any discovery, invention or newly-devised method for obviating or materially diminishing any risk to life, limb or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means" Intending competitors should send in descriptions of their inventions not later than December 31, 1907, to the secretary of the Society of Arts, Adelphi, London, W C

Another of the great teachers who have made Germany famous as a centre of geographical studies has passed away in the person of Dr Alfred Kirchhoff, who died at Leipzig on February 8 at the age of sixty-nine Only two years ago Kirchhoff was compelled by failing eyesight, amid universal regret, to resign the professorship of geography at Halle University, where his fruitful and stimulating labours extended over more than thirty years He wrote various educational works, and only last year supplied, in association with Dr S Günther a valuable treatise on geographical education to Baumeister's "Handbuch der Erziehungs- und Unterrichtslehre fur hohere Schulen" His bent lay naturally in the direction of regional geography, which gave full scope to the many-sided character of his knowledge, and perhaps one of his greatest services was as editor (among other important works) of the series entitled "Forschungen zur deutschen Landes- und Volkskunde," which has now reached its sixteenth volume Some of his studies on the relations between man and his environment attracted wide attention, and were published in a collected volume, which only last year was made available to English readers in Routledge's "Universal Library"

The Association of Italian Manufacturers has issued particulars of an international competition for prizes to be awarded for the prevention of accidents in factories Applications must be made before June 30 1908 to the association 61 Foro Bonaparte, Milan The nature and value of the prizes offered are as follow —(1) A gold medal and 8000 lire (320*l*) for a system to eliminate the danger of a contact (of whatever resistance) between the primary and secondary circuit of alternate-current transformers and their respective lines (2) A gold medal and 1000 lire for a hand-crane or winch so constructed that without sensibly reducing the efficiency or speed of lowering, as compared to ordinary types, any danger due to the rotation of the handles by the descending load is avoided Means must be provided to prevent the rotation of the handles during the descent of the load With each system competing for the prize in apparatus must be supplied which will enable it to be submitted to practical tests

English geologists lament the death, on February 15, of a well-known amateur Miss Caroline Birley Miss Birley was born in Manchester in 1851, and became interested in geological studies at an early age She travelled extensively in search of fossils and minerals and made a large collection, which was placed at the disposal of all to whom it could be of use for purposes of research Her more important fossils were Cretaceous Invertebrata from Faxe Denmark Pliocene shells from Bordighera and Pliocene shells in nodules from the Mekran coast, Baluchistan Her collection of minerals included some fine zeolites obtained from the Færöe Islands All the specimens desired by the British Museum are bequeathed to the nation, while the residue of the collection is given to the Manchester Museum Though herself a diligent and accomplished student, Miss Birley rarely published any notes of her work, but an interesting account of the Chalk section at Faxe from her pen prefaces Dr Henry Woodward's paper on Faxe fossils in the *Geological Magazine* for November, 1901 Miss Birley attended all the meetings of the British Association from 1887 onwards, and she was also an active member of the Geologists' Association The president of the Geological Society and the keeper of geology in the British Museum were present among a large circle of friends at her funeral, which took place at Lingfield, Surrey

A RECENT article distributed by the Decimal Association again directs attention to the advantages to a country of the introduction of the metric system of weights, measures, and coinage. Not the least of these advantages would be the saving of time to business men and workers of all kinds. To children at school the saving of time would be still greater, and this has been estimated with some exactness from figures provided by schoolmasters and others. The association states that the saving in educational time by the exclusive adoption of metric measures would be about 200 hours per child. If coinage also were decimalised, the saving would be increased to about 350 hours. That is, the association says, about 200 million hours a year for every of school-children's time could be saved by a reform which, it is estimated, would cost adults on the average about the equivalent of a day's work (adding the needed mental exertion to the cost of new weights, metre-sticks, and gauges). The Decimal Association asks for legislation to bring about the improvement advocated, but in the meantime good work is being done, and an increasing amount of attention is paid to teaching children at school the simplicity of the inter-relation of the various metric measures. It is interesting in this connection to notice that one of the earliest Parliamentary Bills on the list this session is Mr. B. S. Straus's Weights and Measures (Metric System) Bill, which is receiving strong support. The Bill proposes that from April 1, 1910, all the present British weights and measures shall be replaced by those of the metric system, and that Parliament shall order the Imperial standards to be altered and issued officially as metric standards. The Bill will make it compulsory that every contract or sale shall be by the new standard kilogram and metre. In order to introduce the new system easily, the Bill arranges that local authorities shall provide local standards at least a year before the Act comes into operation. The metric system is one of the subjects to be discussed at the Colonial Conference to be held in London in April.

AN obituary notice of Colonel Mannheim is contributed by Dr. J. Reveille to the *Revue générale des Sciences* for January 30, and may be read with interest side by side with a similar notice of Lieut.-General De Tilly in the Brussels *Bulletin de la Classe des Sciences*, 1906, p. 10, by M. P. Mansion. Colonel Mannheim, who was professor in the École Polytechnique, devoted his attention, in the first place, to theories of transformation in geometry, and his work is noticeable for the prominence given to metric as opposed to projective methods. Under the title of "kinematical geometry," he developed a large and interesting field of study in connection with the displacements of bodies possessing two degrees of freedom. In this case the trajectory of any point of the system consists, not of a straight line, but of a surface, and the properties of these surfaces were studied by Mannheim up to the third order of infinitesimals. They lead to properties analogous to those relating to focal lines in optics, an application which Mannheim was not tardy in using, and his work also contains interesting applications to the properties of deformable surfaces, theories of contact of the third order, and other problems in infinitesimal geometry. Lieut.-General De Tilly, who for some time was professor, and later director, of the Belgian Military College, was author of a large number of works on geometry and mechanics. At the age of twenty-three he published his "Recherches sur les Éléments de Géométrie," and eight years later he published an essay on the mechanics of non-Euclidean space. He too seems to have been attracted by metric rather than projective geometry, for in his "Essai de Géométrie analytique générale" of 1892, he showed that all geometry ultimately reduced to a single relation between $n+4$ points for space of n dimensions. He also wrote papers on ballistics, and was an authority on educational matters.

OWING to inquiries regarding the cultivation of ramie in Jamaica, information on the subject, extracted from several sources, was reprinted in the December (1906) number of the Bulletin of the Department of Agriculture. Mention is also made of a new decorticating machine, manufactured in Germany by Boeken and Co., of Duren, that is portable and low priced.

IN the first number of this year's volume of the *Kew Bulletin*, Mr. T. A. Sprague discusses the synonymy of the Chilian genus Tricuspidaria, defining two species, and Mr. C. H. Wright furnishes a *clavis* for the identification of the Chinese species of Eriocaulon. Mr. G. Massee contributes an account of the heteroecious uredine fungus, *Calyptospora Goeppertiana*, that grows on species of Vaccinium and transfers to fir trees, constituting a pest more particularly of the silver fir, *Abies pectinata*. A note on ramie respecting the experience of an association for producing the fibre in Tirhut, Bengal, is useful as indicating that there are considerable difficulties in the matter of doing so at a remunerative cost. A list of plants suitable for gardens in the warmer parts of the United Kingdom is supplied in the miscellaneous notes.

AMONG the summaries of recent research contained in *Science Progress*, not any are more useful than those which collate allied facts obtained by workers in different sciences. Prof. J. R. Green contributes an article of this nature on protein hydrolysis to the current number (January), in which he indicates how Cohnheim discovered in animals an enzyme, or more correctly a group of enzymes, that he called erepsin as distinguished from trypsin, while independently Vines had arrived at the conclusion that the so-called trypsin in plants is composed of two enzymes acting at different stages. As to the identity of the proteases in animals and plants, it can only be said that arguments tending in this direction may be adduced. Another botanical summary concerned with recent investigations on the fungi is written by Miss A. Lorrain-Smith, and a note on double fertilisation in plants is communicated by Miss E. N. Thomas.

THE growth in the North Andaman Island of the timber tree *Pterocarpus dalbergioides*, known as *padauk*, is the subject of an article in the *Indian Forester* (December 1906) by Mr. F. H. Todd. The vegetative formations of the island consist of a belt of mangrove or littoral evergreen forest, above which the *padauk* forest rises to an elevation of 300 feet, when dense evergreen forest takes its place. It is probable that a sheltered aspect is the chief factor regulating the limits of the *padauk* zone. With regard to the rich red colour that characterises the most valuable timber, as it has been observed in trees of large girth and in dead or dying trees, the author suggests that probably the colour deepens as the tree approaches maturity or decay. In the same number Sir Dietrich Brandis, referring to the identification of certain spruces growing in Sikkim, Chumbi, and Bhutan, remarks upon the anatomy of the leaves as a distinguishing feature, while leaving the determination to foresters on the spot.

PART I. of vol xxvii of the Transactions of the South African Philosophical Society is devoted to the description by Mr. R. Bergh, of Copenhagen, of a collection of South African opisthobranchiate molluscs Hitherto the known South African representatives of this group have been very few, but Mr Bergh has been able to describe quite a number of new species, many referable to the genus Aplysia Owing largely to the influence of currents, there is a marked difference between the marine faunas of the west and east sides of the Cape Peninsula, the latter having a more tropical Indian character Still however, typical forms of nudibranchs do occur on the west side The collection is due to the energy of Dr Gilchrist, after whom one of the species of Aplysia is named

WE have received copies of three papers dealing with injurious insects recently issued by the U S Department of Agriculture In the first of these, forming Farmers' Bulletin No 275, Mr L O Howard discusses the gipsy-moth (*Porthetria dispar*) and the means by which it can best be kept under control This moth we may remind our readers, is a European species accidentally introduced into Massachusetts some forty years ago, since which date it has spread to Rhode Island and parts of New Hampshire Connecticut, and Maine For a long time Massachusetts was left to fight the battle against the invader alone, but the Federal Government has at length recognised its duty of contributing to the expenses of the campaign Of the other two papers forming parts i and vi of Bulletin No 63 of the Bureau of Entomology one is devoted to the hibernation and development of the cotton-boll weevil and the other to its ally the strawberry weevil It has been stated that the best method of destroying the first-named species is by burning or grazing off the cotton stalks in early autumn, so as to reduce by starvation the numbers which hibernate As a large percentage die during hibernation this plan is obviously much more efficacious than are attempts at destruction in spring The strawberry weevil in 1905 inflicted damage on crops in Texas averaging about 12 5 per cent

OF all the statistical reports annually published in the volume on the mineral resources of the United States, issued by the U S Geological Survey, none is of greater interest than that dealing with the production of precious stones, and the report for 1905, an advance copy of which we have received from the author, Dr George F Kunz well maintains the high standard set by preceding reports It deals not only with the production of precious stones in the United States but also with the occurrence and production of precious stones in other parts of the world In the United States the year 1905 was a memorable one, as it marked a record for the importation of precious stones of every variety The value of diamonds and other precious stones amounted to little short of 7,000,000*l*., while the value of the production of precious stones in the United States was 65,250*l* The discovery of utahlite, a green variscite (aluminium phosphate), a translucent green stone used as a gem, at a new locality, forty miles south-west of Salt Lake City, promises to furnish a quantity of this peculiarly American stone that may be used in semi-barbaric jewellery In the mining of tourmaline, beryl, topaz, kunzite, and other stones peculiar to the southern counties of California some wonderful crystals of rose-coloured beryl implanted on felspar and many fine crystals of red and green tourmaline are found, and in connection with them occur many specimens of great mineralogical interest The region bids fair to excel that of the Ural, which for more than half a century has led the world in such products A novel departure has been the cutting of the chrysoprase found at Visalia, California, in its brown matrix, which forms a pleasing contrast to the green colour of the gem The emerald is still the stone most prized, and at no time has it received so high appreciation in price Within the last two years there has been immense improvement in lapidary work in the United States in every variety of stone There has been especial preference for many of the larger stones and never before have aquamarines, tourmalines, and amethysts been sold in such profusion

IN the *Bulletin de la Classe des Sciences* (Brussels) M P De Heen publishes a photograph, taken in the Place Saint Lambert during a thunderstorm, showing remarkable luminous effects emanating from each of the electric arc lamps at the instant of a flash of lightning These effects consist partly of bands of light passing from the lamps to the ground, which the author thinks may be caused by conduction currents, but in addition they include two luminous filaments emanating from each lamp, one forming a closed curve and the other curling round at its extremity in the form of a lasso M De Heen expresses the opinion that these effects have their seat in the ether and cannot be accounted for by any corpuscular (or electron) theory of electricity, but whatever may be said on this point, the discharges in question appear to be well worth careful study

IN the *British Journal of Photography* for February 15 there is an article entitled "British Plates in Germany" in which the writer refers to the great outcry against the increasing imports of English plates into Germany The reader will gather some idea of this great invasion of British-made plates from the following statistics (in kilos) which are given —

1903	1904	1905	1906
9600	23,300	38,700	83,000

The above figures show that, as the writer states, "in open markets the British dry plate has held its own against all comers, and has now shown its capability of disturbing the ranks of manufacturers in a country where home production is favoured and foreign competition handicapped by a tariff" The tremendous increase from the year 1905 to 1906 has been referred to in a German photographic journal as 'gefahrvoll fur die deutsche Industrie" and German plate makers are now taking a serious view of the situation The writer tells us that the cry is raised of German-made glass for the German plate maker, because at the present time the latter has to import his glass from Belgium or Great Britain and "to pay on it pretty nearly as much duty as is paid by the importer of the English plates' A practical illustration of the situation is summed up by the writer, who narrates that when paying a visit to a large German polytechnic, in the instruction rooms he found students being shown the making of positive transparencies on "Thomas's" plates and of carbon prints on 'Autotype" tissue

THE recent public inquiry at Dunfermline with reference to the death of a miner by an electric shock caused by a haulage rope being made alive, directs attention to the very unsatisfactory state of affairs which still exists in a large proportion of our collieries It is lamentable that the present calamity and many previous cases were due to the fact that men who have not been technically trained in electrical work are placed in charge of electrical machinery and although they may be quite practical engineers from

mining and ordinary machinery points of view, are not fitted to examine and overhaul electrical plant The question arises as to what constitutes a "competent person" within the meaning of the Mines Act (Rule 11), and the sooner this is made quite clear and insisted upon the better it will be for all concerned in electrical mining work In the present case, the engineer of the colliery and the "overman" were entruated with the machinery in question, and the evidence proves clearly that they were only expected to see that outside and surface connections were all right, and also to open up switch boxes, but any internal faults and so on were not considered to be within their responsibility Colliery managers must be made to realise that technically trained men should be employed to undertake electrical work in the colliery, and until they do so accidents are bound to occur—the only wonder being that they are not more frequent

PROF R W WOOD has sent us a description of a series of interesting experiments he has made in the direction of the optical intensification of paintings One of the difficulties an artist has to contend with in depicting scenes in which great contrasts of luminosity occur is the narrow range of luminosity obtainable on canvas with pigments Aubert states that the whitest paper is but fifty-seven times as luminous as the blackest and this probably represents about the range obtainable in paintings The problem is, therefore how to produce a strong illumination on all high lights of the picture and a feeble illumination on all the shadows Prof Wood has obtained good results by taking a photograph of the painting on an orthochromatic plate, preferably a red sensitive plate with a suitable ray filter A lantern-slide is then made from the negative and the picture projected in a dark room, not on a white screen but on the original painting Any desired effect can be secured by local reduction or intensification of the negative or lantern-slide If the negative itself is projected upon the painting a most curious effect is obtained The contrast is lessened, and if the negative is a dense one the contrast may be almost destroyed, making the painting appear a flat wash of chocolate In taking the negative care must be taken to have the painting vertical and the camera lens directly in front of the centre of the picture If after looking for a few minutes at a painting illuminated in the way described the lantern-slide is removed and a uniform illumination allowed to fall on the picture, it appears as if it had not been dusted for ten years, the sunlight leaves it, and everything looks flat Prof Wood finds that the effects are very different according to whether the negative is taken on an ordinary or an orthochromatic plate especially if there is much blue in the painting He thinks too, that if the values are correct in the original painting they will hold under the graded illumination produced by the lantern-slide, if they are not right, the errors will be glaringly magnified

No 95 of the Communications from the Physical Laboratory of the University of Leyden contains an account of a series of investigations on the measurement of very low temperatures carried out under the superintendence of Dr Kamerlingh Onnes, the director of the laboratory Mr C A. Crommelin has compared the readings obtained by a thermoelement of constantin-steel with those given by the hydrogen thermometer Mr J Clay has measured the coefficient of expansion of Jena glass and of platinum between +16° C. and −182° C., and compared the platinum resistance thermometer with the hydrogen and the gold resistance thermometer, whilst M. C Braak has made a detailed investigation of the hydrogen thermometer as a means of measuring low temperatures.

THE transformation, which was first observed by Lallemand in 1870, of orthorhombic sulphur, dissolved in carbon disulphide, into a less soluble amorphous variety under the influence of light, forms the subject of a paper by Mr G A Rankin in the *Journal of Physical Chemistry* (vol xi, No 1) The transformation is brought about by the violet and ultra-violet rays, and is reversible, the conversion of the amorphous form into the orthorhombic crystalline variety taking place when it is kept in darkness The presence of ammonia or hydrogen sulphide accelerates the latter change and tends to prevent precipitation from a carbon disulphide solution even in bright sunlight Conditions of equilibrium depending on the intensity of the light can be established between the two forms of sulphur present in solution at a constant temperature

A SECOND edition of Mr. Mervyn O'Gorman's "Motor Pocket Book" has been published by Messrs. A Constable and Co, Ltd The book has been revised and enlarged, and its price is 7s 6d net.

THE writer of the article on the "Treatment of Cancer" in NATURE of December 20, 1906, writes to say that he was in error in believing that the injections of the pancreatic enzymes have to be made in the neighbourhood of the growth (January 10, p 247) He understands that this is not the case, so an objection he raised to the trypsin treatment is removed

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN MARCH —

March 1	11h 42m	Minimum of Algol (β Persei)
,,	14h	Mercury at greatest elongation, 18° 9′ E
4	8h 31m	Minimum of Algol (β Persei)
6	22h. 26m	Conjunction of Mars with the moon, Mars 3° 13′ S
12		Venus. Illuminated portion of disc = 0·639.
16	3h	Conjunction of Vesta with the moon, Vesta, 0° 7′ N
21	6h	Sun enters Aries, Spring commences.
,,	7h 16m to 8h. 30m	Moon occults χ^1 Orionis, (mag 4 7)
,,	12h 30m to 13h. 25m	Moon occults χ^4 Orionis, mag 4 8)
,,	16h. 38m	Conjunction of Jupiter with the moon, Jupiter 2° 32′ N
24	10h 14m	Minimum of Algol (β Persei)
27	7h 3m	Minimum of Algol (β Persei)

A NEW FORM OF CŒLOSTAT TELESCOPE —One of the chief difficulties encountered in the work of the Mount Wilson Solar Observatory has been the deformation and poor definition of the sun's image, caused by the distortion of the mirrors and by the unsteadiness of the heated atmosphere through which the horizontally projected beams have to pass when reflected from the cœlostat to the spectroheliograph or spectrograph

Prof Hale now proposes to obviate some of the difficulties by having the whole instrument vertical, and in No. 1, vol xxv (January), of the *Astrophysical Journal* he describes and illustrates the form of the proposed instrument The cœlostat mirror (diameter 17 inches) is to be mounted on a steel tower some 60 feet high in such a manner that it can be moved to follow the sun without disturbing its adjustments A second mirror, elliptical in form, will again reflect the beam on to a 12-inch objectglass (60 feet focal length) mounted directly below it, and

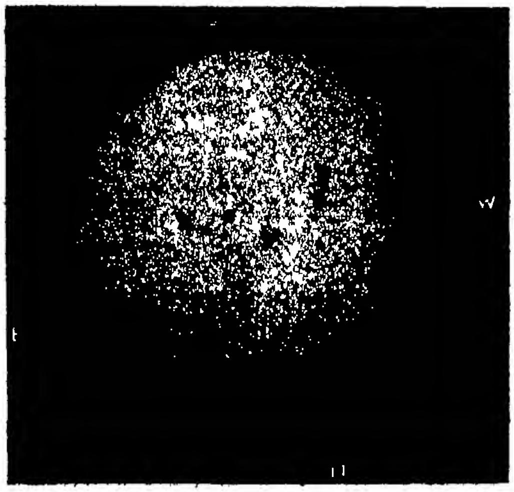
this will focus the image on to the slit of the 30-feet spectroheliograph or that of the Littrow spectrograph, both these instruments will be underground, and will therefore be preserved at a fairly even temperature

To prevent its distortion, each mirror is to be 12 inches thick, and will be silvered on both sides, and, if necessary, heated on the back by reflected or direct sunlight An electric motor will drive the photographic plate across the secondary slit of the spectroheliograph, and will by means of a vertical shaft impart a synchronous motion to the 12-inch lens, and hence to the sun's image

The Littrow spectrograph is to be fitted with an 8-inch plane grating, and will be employed in the study of the solar rotation and in the photography of sun-spot spectra

THE RECENT LARGE GROUP OF SUN-SPOTS —Another large group of sun-spots visible to the naked eye—of which the solar maximum through which we have just passed has furnished an abnormal number—was observed during the former half of the present month

The first signs of this group appeared on February 6, when two small nuclei were seen on the eastern limb about 15° south of the equator, and these were followed by two similar spots on February 8 On February 9 a larger spot brought up the rear of the group, which then contained a large number of small umbræ In London,



Photograph of sun taken oh 47m February 11, 1907

bad weather prevented the daily observation of the development of the group but on February 11 it was easily visible to the naked eye, and was seen to have developed a second fairly large spot at its preceding extremity The accompanying reproduction is from a photograph taken at oh 47m on that date, and it may be seen that the preceding spot was then the largest in the group and had a peculiar kidney-like shape The total affected area was then roughly rectangular, with a length of about 115,000 miles and a breadth of about 55,000 miles Naked-eye observations of two groups were possible on February 14 The larger group formed a striking spectacle on the western limb on February 18 but had disappeared from view when the sun was observed on the following day

THE SPECTROSCOPIC BINARY λ ANDROMEDÆ —From a number of spectrograms of λ Andromedæ, taken with the Mills spectrograph, 1897–8–9, a set of elements for the orbit of the binary has been computed by Mr Burns, of the Lick Observatory On comparing these elements with those determined from more recent spectrograms, taken with the re-mounted Mills spectrograph, it is seen that there are material differences which can only be reasonably accounted for by the supposition that the orbit itself has been modified The discrepancy, if established, will probably be found to be due to a third body in the system of this star (Lick Observatory Bulletin, No 105)

THE GROWTH OF MICRO-ORGANISMS [1]

THE author, early in the past year, began to make experiments on the origin-of-life question, with various saline solutions containing ammoniacal salts After a time he found the best results were to be obtained with one or other of two solutions, one of which contained small quantities of sodium silicate, ammonium phosphate, and dilute phosphoric acid in distilled water,' and the other a simple solution of sodium silicate with liquor ferri pernitratis in distilled water It was found, also, that with the use of these saline solutions exposure of the experimental vessels to diffuse daylight, with even a mean temperature of only 60° F to 65° F, favoured the appearance of microorganisms quite as much as, or even more than, darkness associated with an incubator temperature of 95° F

The solutions were placed in previously superheated tubes, which, after being hermetically sealed, were heated again in a calcium chloride bath to 239° F (115° C), 248° F, 257° F, or 266° F (130° C), for ten to twenty minutes, In all these tubes, after the process of heating, a small deposit, either of silica alone or of silicate of iron, was thrown down The tubes were subsequently exposed either to diffuse daylight or else in the incubator, and mostly for periods varying from five weeks to four months When opened, the tubes were found to contain in varying abundance, one or more kinds of micro-organisms, photographs of which were shown

One point of much interest in connection with these experiments is the fact that no carbon was ostensibly contained in the solutions, though its close chemical ally silicon, was always present

It had previously been determined that such solutions proved excellent nourishing media for the growth of micro-organisms, and this fact led to trials whether any evidence was to be obtained tending to show that such solutions could also actually engender living units On examination of the contents of the tubes after their prolonged periods of exposure to light or in the incubator the organisms were always found, after careful search on or within the substance of the flakes of silica, while the fluid above remained perfectly clear

Many organic compounds have been discovered by chemists in which silicon wholly or in part replaces carbon, and it is contended that there is good *primâ facie* evidence from these experiments tending to show that silicon is capable of entering into the composition of protoplasm itself —that is, wholly or in part taking the place of carbon

In regard to the major question, concerning the origin of life itself, the facts to be borne in mind are these —If a few hours after the heating of the tubes one or more of them be opened as "control" experiments and the sediment carefully examined, no organisms of any kind are to be found, but, after suitable periods of exposure organisms may be found, in more or less abundance in the sediment taken from other similar tubes Here, then, is evidence that *the organisms are living*, they have appeared and multiplied within sealed tubes, though at earlier dates none is to be found

Then again, it is important to bear in mind (1) that, apart from "spores" of bacilli, no micro-organisms can resist an exposure of two or three minutes in boiling water this being lethal for bacteria vibriones, micrococci, torulæ and moulds, and (2) that all ordinary spores of bacilli are killed by a similar exposure for a minute or two to 115° C (239° F)

It is concluded therefore, that the bacteria, bacilli vibriones, micrococci torulæ, and moulds which have been taken from hermetically-sealed tubes previously heated to 115° C 120° C, 125° C, and 130° C for ten to twenty minutes must have been engendered *de novo* within these vessels

The organisms that arise *de novo* are presumed by the author to assume well-known forms, for precisely the same reason that the various representatives of the crystalline world *when they originate*, invariably fall into their own specific shapes and with surfaces always inclined to one

1 "On the de-novo Origin of Bacteria, Bacilli Vibriones, Micrococci, Torulæ and Moulds in certain previously superheated Saline Solutions contained within hermetically sealed Tubes By Dr H Charlton Bastian F R S. Read before the Royal Medical and Chirurgical Society on January 22

another at angles that never vary for each particular species of crystal The forms in each set of cases—in organisms and in crystals alike—may be regarded as the necessary resultants of the molecular constitution of their initial units in the particular media and surroundings in which they occur

PROPERTIES OF ALLOYS[1]

THE research described in the report was carried out by the authors with the cooperation of the Broughton Copper Co, Manchester, and the British Aluminium Co, Milton, who furnished respectively the best *commercial* copper and aluminium for making the alloys, undertook the rolling and drawing of the materials, and made special castings where necessary

The salient points of the report are stated as follows —

(a) The number of alloys that have been found of any industrial and technical promise is small Such alloys are chiefly those very rich in copper At this end of the series the limit of serviceable alloys must be placed at 11 per cent At the other end of the series the limit is even smaller Among the specifically light alloys rich in aluminium the limit is probably not higher than 4 per cent of copper Between 11 per cent and 96 per cent of aluminium (exclusive) the alloys do not appear to be of any practical promise

(b) But if the range of serviceable alloys is narrow, their quality is certainly high in several instances This statement holds for certain of the rich copper alloys containing between 7 per cent and 10 per cent of aluminium It is not going too far to say that in certain respects the best of them equal, and even surpass, high-quality steels of the same general character

The following summary refers only to the rich copper alloys —

(c) Four features of the results of the tensile stress tests of outstanding interest merit a special comment

(1) In view of the doubt which exists at the present time as to whether copper and its alloys possess true yield-points, it is important to record that from 0·1 per cent to 9 per cent of aluminium the alloys possess clearly marked yield-points

[1] Abstract of the Eighth Report to the Alloys Research Committee On the Properties of Alloys of Aluminium and Copper By Prof H C. H Carpenter and Mr C A. Edwards, of the National Physical Laboratory Read at the Institution of Mechanical Engineers on January 18

(*a*) It has been recently shown by Messrs Stanton and Bairstow (Proceedings of the Institution of Civil Engineers, 1906) that the primitive yield-point of a rolled or forged steel is usually an artificial figure, and is due to a *stiffening* caused by this mechanical treatment Such is not the case with these alloys Their primitive yield-point is the true one

(3) The ductilities (considered as a product of the percentage elongation and reduction of area) of alloys containing from 0 1 per cent to 7 35 per cent of aluminium are very high and practically constant, even although the tenacity increases markedly with rise of aluminium

(4) The tenacity and ductility of the widely-known "aluminium bronze" or "gold," containing 10 per cent of aluminium, have been found to be as good in the form of *small chill castings* as in the *rolled bar*, where an 80 per cent reduction of area of the original ingot has been effected So far as the authors have been able to learn, this result has no parallel At their request, therefore, independent tests were instituted at the Broughton Copper Works, and these have confirmed the above result which may have important practical consequences

(*d*) The research has brought to light several striking instances of the profound influence of a small quantity of aluminium upon copper, notably in the tension tests, but especially in the torsion and electrical conductivity experiments One-tenth of 1 per cent raises the angle of twist of copper in torsion 90 per cent , it lowers the electrical conductivity 23 per cent

(*e*) The behaviour in torsional stress of the alloys containing from 0 1 per cent to 7 35 per cent of aluminium is one of the outstanding features of the report

(*f*) The alloys containing from 5 per cent to 10 per cent of aluminium have come well out of the dynamic stress tests The particular merit of alloys Nos 9 and 13 when tested in alternating stress is the close approximation of the maximum stress under which they will bear an unlimited number of reversals to the stress at the elastic limit as determined in a tensile test *In this respect they are markedly superior to the iron and steel specimens hitherto investigated*

Alloys Nos 6, 9, and 13 stood up well when repeatedly stressed beyond the yield-point in Arnold's test In fact Prof Arnold has informed the authors that "Alloy No 9 constitutes a record in its capacity of resisting alternations "

(*g*) At about 15 per cent of aluminium the alloys are entitled to rank with quenched steels in *hardness* Thus the hardness number of No 17 (15 38 per cent) in the *cast* state (untreated) is 539, which is about that of a 0 45 per cent carbon steel quenched in water at 20° C (68° F), and is only slightly lower than that of a 0 66 per cent carbon steel similarly treated

(*h*) In the corrosion tests, which were purposely made as severe as possible alloys containing from 1 per cent to 10 per cent of aluminium have shown themselves to be practically incorrodible by sea-water, whether alone or bolted to a plate of mild steel In these tests they showed themselves superior both to Muntz metal and naval brass, which corroded appreciably In tap water of medium temporary hardness the positions were exactly reversed

(*k*) In view of the discussion in the previous report as to the trustworthiness of temperatures measured with a protected thermo-junction, the exact influence of the jacket (a fire-clay tube 1/16th inch in thickness) between temperatures of about 1100° C and 550° C (2012° F and 1022° F) has been determined It has been found to cause a lowering of not more than 3° C (5° 4 F) at the higher, and 9° C (16° 2 F) at the lower temperature and above 800° C (1472° F) comes *within* the experimental errors and uncertainties of the method

(*l*) Finally, a special comment must be made on the truly extraordinary similarity in physical and mechanical qualities between alloy No 13, which consists of 90 06 per cent of copper +9·90 per cent of aluminium, and Swedish Bessemer rolled steel of about 0 35 per cent of carbon and thirty-eight tons per square inch ultimate tensile stress

A PROPOSED INTERNATIONAL ATTACK ON THE SIDEREAL PROBLEM

IN a brochure[1] written by Prof J C Kapteyn, of the Groningen Astronomical Laboratory, the author outlines the chief points of a very comprehensive attack which he proposes should be made as soon as possible, on the main problems concerning the structure of the sidereal universe

Whilst the "Carte du Ciel," parts of which are now approaching completion, gives us the relative projected positions of all the stars down to the eleventh magnitude and will, by duplication after a number of years, afford material for the accurate determination of proper motions, it leaves untouched the extremely important question as to the distribution of different stellar types in actual space Prof Kapteyn proposes to supplement this enormous work by the preparation of a Durchmusterung which shall contain all the necessary data for a preliminary discussion of the structure of the universe In fact he proposes that in the same way that the geological has supplemented the geographical study of the earth, so shall an *astrological* supplement our astrographical study of the heavens, but it is obvious that to attempt a scheme like this for the *whole* of the heavens at once would be to court failure The plan would probably die of senile decay ere it showed sufficient results to have justified its existence For this reason, and acting on the advice of eminent astronomers who favour the idea of such a survey, Prof Kapteyn limits his proposals to a number of selected areas of the sky This would reduce the work immensely and would probably lead to a first approximation of the truths which it is hoped to educe

The general scheme is based on the method of "gauging" as carried out by the Herschels, only that now instead of considering simply the numbers of stars, every ascertainable fact in regard to the objects studied must be considered The chief data to be obtained as enumerated by the proposer of the scheme, are visual magnitudes photographic magnitudes, spectral types astronomical proper motions, radial velocities, and parallaxes to which list he adds the determination of the amount of light received from different parts of the sky, as being a subject of great importance to the problem under consideration

As Prof Kapteyn points out, there are already sufficient data for the brighter stars, partially excepting parallax and photographic magnitudes, to allow of a fairly thorough statistical treatment, but much of this data needs a great amount of arrangement and classification ere it can be included in a homogeneous attack The great need in such an inquiry as that proposed is the international study of the *fainter* stars Work already completed or now in hand, will take us down to the seventh or eighth magnitude for most of the elements named, but it is self-evident that, in any attempt to solve the riddle of sidereal structure, the Milky Way is an all important feature, and therefore, far fainter magnitudes than this must be included

Put into its briefest form the scope of Prof Kapteyn's proposals is —"For 206 areas regularly distributed over the sky and for another less extensive series of particularly interesting regions, to obtain astronomical data of every kind for stars down to such faintness as it will be possible to get in a reasonable time " The 206 areas first named come under the designation of "the systematic plan" and are again divided into two classes, the first of which would comprise 118, and the second eighty-eight areas These are so arranged that the first class might be completed independently of the second and would furnish sufficient data for a first approximation Then if there were evidence that this could be executed in reasonable time the second class might be intercalated without interfering with the other except to provide further data which would in all probability enhance the value of the final

[1] Plan of Selected Areas By Prof J C Kapteyn (Groninge 1906

results to an extent incommensurable with the extra labour involved

The 206 areas would include 400 square degrees of the sky, and this full scheme would entail the following labours:—The determination of the rough positions and sharply defined photographic magnitudes of some 200,000 stars, visual magnitudes for the same 200,000, the determination of the accurate proper motions, to within 0"·01 in each coordinate, of some twenty thousand of these objects. For the same twenty thousand, parallaxes are necessary, and for as many of them as is possible the class of spectrum and the radial velocities must be determined. Finally, the determination of the total amount of light received from different parts of the sky would complete a set of homogeneous data from which undreamt-of additions to our knowledge of the sidereal universe might accrue.

In addition to this "systematic plan," Prof. Kapteyn, after much correspondence and discussion with a number of eminent astronomers, has decided on a scheme for the elucidation of "special areas." This scheme includes forty-six areas such as those in the Milky Way which show intense variations of star-density, the rifts and branches of the Milky Way, and extra-galactic areas where nebulæ or strong contrasts in star-density are preponderant.

Many interesting devices to further the plan are discussed by Prof. Kapteyn, e.g. the determination of colour, and hence the probable spectrum class, from the comparison of the photographic and visual magnitudes in the cases where the stars are so faint that these features cannot be determined by the usual methods; again, the determination of proper motions and parallaxes from plates exposed a second time after an interval of some years. Possibly Prof. Wolf's stereo-comparator method of determining proper motions would materially curtail the interval necessary between the two exposures.

Considering a few details, it is seen that the scheme includes:—(1) 9710 exposures on 2620 plates, in addition to the plates for the determination of the radial velocities of three or four standards in each area. (It is intended that the bulk of the radial velocities shall, if possible, be determined by one of the wholesale prismatic-camera methods such as those proposed by Herr Orbinsky, Prof. E. C. Pickering, and Prof. Comstock.) (2) Visual observations of 3024 standard magnitudes, the determination of the magnitudes and positions of 200,000 stars, and the meridian observations of some 2600 stars for proper-motion standards. (3) The measuring of nearly 1½ million images.

Prof. Kapteyn, with all his experience, is quite ready, should the essential funds be forthcoming, to undertake a greater part of the measuring work, and could, at present, undertake to perform half his proposed share. A number of other well-known astronomers, as may be seen from the letters which he publishes at the end of his brochure, are definitely and enthusiastically in favour of the project, and are willing to grant what aid is in their power, so that the scheme cannot be looked upon as immature or as entailing insuperable difficulties.

Accepting for the moment that the plan, in its entirety, is feasible, the *possibilities* attached to the discussion of the results are obviously infinite. In some fifty or a hundred years the "Carte du Ciel," if repeated, will probably afford a series of definitive proper motions which can then be discussed from the sidereal structure standpoint, but of the spectral layers in the visible universe it would leave us in almost total ignorance. On the other hand, the results from Prof. Kapteyn's plan would probably afford all the information attainable by human effort of the sidereal strata or groups, or drifts, or a thousand and one other features.

As an earnest of what might accrue from such a discussion, one may cite the remarkable result recently derived by Mr. Eddington from the analysis of the relatively meagre data of the Greenwich-Groombridge proper motions (see Nature, No. 1938, p. 182, December 20, 1906), a result first derived, in a qualitative form, by Prof. Kapteyn himself from a discussion of the Bradley proper motions.

W. E. Rolston.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—At a meeting of members of convocation in Magdalen College on February 23, which had been summoned by the Vice-Chancellor to consider the election of a Chancellor of the University, there seemed to be a majority in favour of the nomination of Lord Curzon.

The published accounts of the common university fund for 1906 show that the income for that year was 6937*l*., and the expenditure 6395*l*., of which sum 3577*l*. was devoted to scientific objects.

Cambridge.—The Smith's prizes have been awarded for the following essays:—"Fluorescence," G. R. Blanco-White; "The Systematic Motions of the Stars," A. S. Eddington; "The Bending of Waves Round a Large Opaque Sphere and some Associated Problems," J. W. Nicholson; "The Variation of the Absorption Bands in the Spectrum of a Crystal under the Action of a Magnetic Field," W. M. Page. The names are arranged in alphabetical order. The essay on "Some Problems on the Diffraction of Electric Waves," by H. J. Priestley, is awarded honourable mention.

H. R. Hassé has been elected to the Isaac Newton studentship, tenable from April 15, 1907, to April 15, 1910. The student will carry on a course of research in physical optics.

W. Spens has been elected fellow at Corpus Christi College, and has also been appointed director of natural science studies in the college.

Dr. Harmer, the superintendent of the Museum of Zoology, announces the receipt of a cast of a skeleton of *Diprotodon australis*, presented by Dr. E. C. Stirling, F.R.S., director of the South Australian Museum at Adelaide. Dr. Harmer also records the gift of a valuable consignment of some nine skeletons and forty skulls and skins of mammals, mostly antelopes, from tropical Africa, presented by Mr. C. B. C. Storey, of Clare College.

The Cavendish Laboratory Extension Syndicate has proposed plans for the new laboratory running along Free School Lane, which will cost between 7000*l*. and 8300*l*. Towards defraying the cost of this building there is available Lord Rayleigh's gift of 5000*l*. out of the Nobel prize, and Prof. Thomson is able to find 2000*l*. from the laboratory funds.

The recommendation of the general board of studies that a university lecturer in pathology be appointed, in connection with the special board for medicine, with an annual stipend of 100*l*. payable out of the common university fund, will be brought before the Senate on March 9.

It is proposed to nominate Prof. A. Thomson to be a member of the board of electors to the professorship of anatomy; Sir E. C. Perry, a member of the board of electors to the Downing professorship of medicine; Prof. Graham Kerr, an elector to the professorship of zoology; Dr. Anderson, an elector to the chair of physiology; Prof. Middleton, an elector to the Drapers' professorship of agriculture; and Prof. Langley, to that of botany.

The local examinations and lectures syndicate has appointed E. A. Parkyn and D. H. S. Cranage as delegates at the International Congress on School Hygiene to be held in London in August.

Mr. J. J. Lister has been appointed a manager of the Balfour fund until June, 1909, in succession to the late Sir Michael Foster.

Mr. F. A. Potts has been nominated to occupy the University table at the laboratory of the Marine Biological Association at Plymouth for one month during the ensuing Easter vacation.

The Mercers' Company has made a donation of fifty guineas, and the Grocers' Company one of ten guineas, to the South-Eastern Agricultural College.

At the South-Western Polytechnic on March 15 the Lord Alverstone, G.C.M.G., Lord Chief Justice of England, will present prizes and certificates to students of evening classes and of the day college.

THE Goldsmiths' Company has undertaken to provide the 8000l. required for the completion of the new wing of Goldsmiths' College at New Cross The site and buildings were presented by the company to the University of London for educational purposes in 1904.

THE treasurer of Guy's Hospital has received a bequest of 1000l. under the will of the late Dr C J Oldham, of Brighton, for the purpose of endowing an annual prize in ophthalmology at the medical school A further anonymous donation of 200l has also been received for the fund of the endowment of medical education and research

MR. HAROLD HILTON has been appointed lecturer in mathematics at the Bedford College for Women (University of London) Mr Hilton is a former fellow of Magdalen College, Oxford, and has for the past five years been on the teaching staff of the University College of North Wales He is the author of a treatise on the mathematical theory of crystallography, and of numerous papers published in the Proceedings of the London Mathematical Society and elsewhere

SINCE the disastrous fire which partially destroyed the main building of the Merchant Venturers' Technical College, Bristol, in October last, various sites for the re-erection of the college have been suggested and carefully discussed A report advising the retention of the present site was adopted by the Society of Merchant Venturers on Friday last, and steps will, therefore, be taken at once to replace the various laboratories, workshops, lecture theatres, &c, with all possible speed In framing plans for re-building, the Merchant Venturers will bear in mind the possibility that at some future period the college may be called upon to take its proper part in the formation of the proposed University of Bristol

THE Board of Education has issued a return showing the extent to which, and the manner in which, local authorities in England and Wales have applied funds to the purposes of technical instruction and other forms of education other than elementary during the year 1904–5 The total number of authorities having powers in respect of education other than elementary was, for the year under consideration 1203; of these sixty-three were county councils, seventy-one county borough councils, and the remainder councils of non county boroughs or urban districts All the county councils and county borough councils, and 431 of the councils of non-county boroughs or urban districts, incurred expenditure for higher education Particulars are provided as to money spent upon secondary schools, including pupil-teacher centres, evening schools and institutions for higher and technical education, exhibitions including payment of fees, salaries for administrative officers, legal expenses and general administration, and in respect of loans The total expenditure in England and Wales on higher education, understood as including the work of institutions mentioned, was, in 1904–5, 2 889,871l The amounts under the more important headings were —secondary schools, 736,966l, evening schools and institutions for higher and technical education, 1 382,162l, exhibitions 248,007l, training of teachers, 48,835l administrative and legal expenses 152,605l The detailed information provided in the tables should prove of great value to members of education committees desiring to compare the expenditure in their own districts with that in other areas

MR McKENNA, President of the Board of Education, addressed a letter on February 19 to Sir Francis Mowatt the first chairman of the departmental committee on the Royal College of Science, concerning the proposed Imperial College of Applied Science at South Kensington, to the delay in the inauguration of which we referred last week Mr McKenna says that the time which has elapsed since the appearance of the committee's report has not been wholly wasted, because the problem has become clearer and the institutions concerned have become more nearly agreed as to the necessities of the case After reviewing the alternative courses pressed upon the consideration of the Board of Education, the president expresses the opinion maintained in these columns that the points of determinative importance in the whole situation now is that there should be no further avoidable delay in bringing about the establishment of the new institution The gratifying announcement is then made that the King is to be petitioned for a Charter for the new institution on the lines unanimously recommended by the departmental committee in January, 1906, and set forth in the draft proposals circulated by the Board of Education last July The special governing body suggested by the departmental committee is to be appointed forthwith, and the institution to be developed as soon as possible Mr McKenna concludes his letter by requesting Sir Francis Mowatt to intimate to the Senate of the University of London that after an interval of time sufficient to permit of the full development of the governing body for the new institution, he will be prepared to advise the appointment of a Royal Commission to consider whether the amalgamation of the new institution with the University of London is desirable and feasible

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 13, 1906 —"Further Observations on the Effects produced on Rats by the Trypanosomata of Gambia Fever and of Sleeping Sickness" By H G **Plimmer** Communicated by Dr C J Martin, F R S

From the results of 211 experiments, extending over a period of nearly three years, it appears that the tentative deductions which the author made in his preliminary note (Roy Soc Proc, vol lxxiv) from the few experiments therein recorded, that Gambia fever and sleeping sickness are two distinct diseases, cannot be maintained

This extended series of experiments and observations goes to show that each of these two strains of Trypanosomata has produced two different effects in the same class of animals, under conditions of which we at present know nothing, that these effects are alike for the two organisms, and that the Trypanosomata found in these two types of disease are one and the same organism, modified by passage from man through monkeys to rats and perhaps in the strains used by the author, by transplantation into animals of, and in another country

Faraday Society, January 29 - Prof H E Armstrong, F R S, in the chair -- Discussion on osmotic pressure opened by the **Earl of Berkeley,** who exhibited and described his apparatus for the direct measurement of osmotic pressure The ordinary direct method of measuring osmotic pressures is to obtain equilibrium on the two sides of the semi-permeable membrane by means of the pressure of a head of liquid The method devised by the author and Mr E G J Hartley substitutes mechanical pressure, which is put straight on to the solution and equilibrium thus obtained A vapour-pressure method for measuring osmotic pressure was also described —Indirect methods of measuring osmotic pressure W C Dampier **Whetham** The speaker agreed as to the importance of the vapour-pressure method He discussed the formula used by Berkeley and Hartley and explained the difference between it and the van 't Hoff formula obtained from thermodynamic considerations, the expressions being identical where there is no change of volume of the solvent as it enters the solution --Osmotic pressure from the standpoint of the kinetic theory Dr T M **Lowry.** The application of the equation $PV = RT$ to the osmotic pressure of gases could be predicted on general theoretical grounds, but there was no *a priori* reason for supposing that it would be applicable to the case of liquids In the early years of the osmotic discussion it had been assumed by van 't Hoff and others that since osmotic pressures and gas pressures could be calculated by means of the same formula the conditions must be identical in the two cases and it was definitely stated that in dilute sugar solutions the osmotic pressure was wholly due to the bombardment of the membrane by the molecules of the sugar the effects produced by the water molecules being substantially identical on either side of the membrane The alternative view that osmotic pressure represented a diminution in the activity or "active mass" of the solvent was suggested by Poynting in 1896 and had sub-

sequently been advocated by Armstrong, Beilby van Laar, and others The simplest case of a semi-permeable membrane is undoubtedly to be found in the surface of separation between liquid and vapour At such a surface the kinetic theory postulates a continual interchange of molecules between the two phases But whilst the rate of escape or evaporation would be reduced by the presence of non-volatile molecules in the surface, the rate of condensation would be unaffected, and equilibrium could only be restored by decreasing the vapour pressure, and so diminishing the rate of condensation at the surface of the solution In this case a quantitative relationship could be deduced —The bearing of actual osmotic experiments upon the conception of the nature of solutions Prof L **Kahlenberg** The occurrence of osmosis and its direction and extent are determined by the nature of the septum and of the liquids that bathe it Experiments have shown, too, that there is always a major and minor current present following in opposite directions, although it often appears as if the osmotic process were one sided In this case the septum is termed "semi-permeable," and recent research has centred around so-called semi-permeable membranes which really do not exist The author has demonstrated that it is peculiarly strong selective action on the part of the septum which causes it to be approximately semi permeable in certain cases and he has recently even succeeded in separating two colloidal substances by dialysis This selective action is due to the solubility or insolubility of the substances concerned in the membrane, and therefore osmotic pressure is due to the same forces—essentially chemical in character in the opinion of the author—as the process of solution, and they may be quite variable as different septa and different liquids are employed The usually accepted "sieve theory" is untenable because larger molecules frequently go through a membrane more readily than smaller molecules —Tables containing a summary of the recent experiments made with glucose and cane-sugar H N **Morse.** The conclusions arrived at are —(1) In the vicinity of 20° the osmotic pressure exerted by either is equal to that which a molecular equivalent quantity of a gas would exert if its volume were reduced, at the same temperature to the volume of the solvent in the pure state (2) Between 18° and 26°, at which the measurements were made both cane sugar and glucose in solution are in the anhydrous condition Measurements made just above 0° yield pressures somewhat above the calculated gas pressures Measurements with electrolytes are about to be made in which osmotic pressure and dissociation will be determined simultaneously

Entomological Society, February 6 —Mr C O Waterhouse president, in the chair —*Exhibitions* —L A **Cockayne** A collection of Lepidoptera made at Tongue, North Sutherlandshire between June 30 and July 13, 1906, comprising many species not hitherto reported from the county The several species showed little tendency to melanism —Dr T A **Chapman** Specimens of *Hastula hyerana*, Mill to demonstrate how it may vary towards melanism in the circumstances of late or retarded emergence —Miss M E **Fountaine** Examples of Anthocharid and Melitaeid butterflies from various localities in the Palæarctic regions showing a wide range of variation —The **President** A female example of the genus Dorylus from Mengo in Uganda and one small and two large workers, which would probably be the means of identifying the species The workers closely resemble specimens in the museum named *D arcens* which are said to be the same as *nigricans* —Rev F E **Lowe** Various aberrant forms of Swiss butterflies, including *Melanargia galatea*, ab *fulvata*, Lowe, from Martigny *Lycaena arion*, from Pontresina, with the black markings on the underside of the wings almost entirely absent, save one very large kidney-shaped spot, slightly tinged with white at the centre of each wing and a pair of *Pieris napi*, var *bryoniae*, taken *in cop* at Caux the ♂ not only suffused as in *bryoniae*, but also having the ♀ markings —Colonel Charles T **Bingham** The pupa of a Tineid moth, probably of the genus Brinsitta, from Upper Burmah presenting with its surroundings a remarkable mimetic resemblance to the head and body of a snake, and a case showing the curious habit of butterflies of the genera Gerydus and Allotinus attending with ants on Aphidæ for their sweet exudations —Rev F D **Morice** A very remarkable gynandromorphous specimen, from Silchester, of the common fern-visiting sawfly, *Strongylogaster cingulatus*, the dividing line between the ♂ and the ♀ portions running longitudinally, not transversely, from end to end of the creature, a form probably unique —*Papers.*—Notes on the Indo-Australian Papilionidæ Percy I **Lathy.**—The hymenopterous parasites of Coleoptera E A **Elliott** and Claude **Morley.**

Geological Society, February 6 —Dr J E. Marr, F R S, vice-president, in the chair —Note on the cervical vertebra of Zeuglodon from the Barton Clay of Barton Cliff (Hampshire) Dr C W **Andrews.** The author gives a brief description of a cervical vertebra from the Barton Clay of Barton Cliff It is referred provisionally to *Zeuglodon wanklyni*, a species described in 1876 by Prof H G Seeley The skull on which this description was founded is totally lost, so that this vertebra is the only bone of a Zeuglodon from the Barton Clay, and, with the possible exception of a vertebra from the Brockenhurst beds (which is the type of *Balaenoptera juddi*), the only one found in the British Isles that now exists —The origin and age of the plateaus around Torquay A J **Jukes-Browne.** The existence of high-level plains or plateaus near Torquay has long been known, but since Pengelly's time little attention seems to have been paid to them Pengelly believed that there were several such plains at different levels, and thought that the time of their production was not very remote On examination, however, his evidence breaks down, and the author regards the plateaus as portions of one inclined plain The age of the planation is shown to be post-Permian, by the fact that Permian breccia forms part of the plateau-surface at St Marychurch It is also probably post-Cretaceous because Cretaceous planation is not likely to have removed all the Permian Its present dissected condition shows that it is older than the Pleistocene, and consequently an Eocene date would agree with local evidence

Linnean Society, February 7 —Lieut Colonel Prain, F R S vice president in the chair —Some observations of climbing plants Rev John **Gerard,** S J The author began by pointing out the two opposing methods of describing spiral growth or torsion as viewed from the exterior or from the interior of the spiral, the result being that the "dextrorse" of the first is the "sinistrorse" of the second method With or against the sun, which applies to the northern hemisphere, is reversed in the southern hemisphere, and for these reasons he preferred to use the terms "clockwise" and "counter-clockwise" (shortened to "counterwise") the honeysuckle (*Lonicera Periclymenum*) and the hop (*Humulus Lupulus*) turning clockwise, and the convolvulus (*Convolvulus arvensis*) and the scarlet-runner bean (*Phaseolus vulgaris*) twining counterwise He showed the result of some experiments he had made by growing scarlet-runner beans in opaque cylinders to discover, if possible whether the deviation of the twist were innate, or from the direction of the light, the conclusion being drawn that the plant possessed an inclination resembling the instinct of animals, of proceeding in a given direction and resented any attempt to force it otherwise The author concluded with some observations on the behaviour of tendrils as those of *Bryonia dioica*, displaying one specimen which had varied the torsion four times, and showed ten turns in one direction against seventeen in the contrary —New plants from Malaya. Dr Otto **Stapf** The author gave the history of his new genus Hallieracantha, which receives eight species from the genus Ptyssiglottis, Hallier f, and eleven others are added from the Kew collections, they form a very homogeneous group, are eminently shade-loving plants, and exhibit anisophylly in a very marked degree The headquarters of the genus are in Borneo —Tertiary Foraminifera of Victoria The Balcombian deposits of Port Phillip F **Chapman.**

Physical Society, February 8 —Prof J Perry, F R S, president, in the chair —Annual general meeting —Presidential address Prof **Perry.** In concluding his address, Prof Perry remarked that a standard boy should know decimals at eight, he should use squared

paper to record his own experimental results at nine, he should solve interesting problems using squared paper and logarithms and tables of sines and cosines at the age of ten and eleven, and he should get the notion of a rate long before he was twelve. He would have an elementary knowledge of the infinitesimal calculus before he was fourteen. He considered the elementary use of the calculus, and even the solution of easy differential equations, a school and not a university subject. Spherical harmonics and Bessel functions and their use in all sorts of physical problems with actual curve drawing was an undergraduate study. Permutations and combinations and the theory of probability were post-graduate subjects, like the study of the fifth book of Euclid.—The magnetic field and inductance coefficients of circular, cylindrical, and helical currents: A. **Russell**. The author gives formulæ for the magnetic force near a circular current which can be readily evaluated. He then shows how the self-inductance of a ring of wire and the mutual inductance between two coaxial circular filaments can be found without using Neumann's theorem. By Kelvin's method, the results obtained can be applied at once to the corresponding problem of the simple vortex filament in hydrodynamics. In this way expressions are found for the velocity of translation of a circular vortex filament—about which there appears to be uncertainty in hydrodynamical theory—and for the energy of the motion. The exact formula for the mutual inductance between a cylindrical current sheet and a coaxial helical filament of current is obtained. It is expressed both in terms of elliptic integrals and in the form of an algebraical series.

MANCHESTER.

Literary and Philosophical Society, December 11, 1906.—Mr. Francis Nicholson in the chair.—The discovery by Butschli of strontium sulphate as the basis of the skeleton in certain Radiolaria (Acantharia): Dr. F. W. **Gamble**. Working with material brought back by the German Antarctic Expedition, and also upon Mediterranean Acantharia, Butschli has shown that strontium sulphate is the material of which the complex rods and spicules of these Radiolaria are composed. This is the first time that strontium has been described in animal tissues, and coincides with the recent discovery of barium sulphate in certain other deep-sea Protozoa (Xenyophophoridæ).—The parichnos in the Lepidodendraceæ: Prof. F. E. **Weiss**. This somewhat problematical organ appears as two small marks on the leaf scars of Lepidodendron and Sigillaria. It is found to consist of a thin-walled tissue communicating with the interior of the stem, and has been regarded by some as concerned in the transpiratory function of these extinct plants. Prof. Weiss brought forward arguments in favour of comparing them to the breathing pores of trees known as lenticels.—The structure of Syringodendron, the bark of Sigillaria: Miss K. H. **Coward**. An account was given of a particular instance of the above-mentioned breathing pores in Sigillaria.

January 15.—Sir W. H. Bailey, president, in the chair.—The positions of Mendeléeff's groups of chemical elements: C. E. **Stromeyer**. With the help of an empirical formula, which, like Stoney's logarithmic spiral of the cube roots of the atomic weights, gives average results, the author has calculated the mean positions of the various chemical groups, and finds that they are not equidistant, but are irregularly spaced like the musical notes of the major or minor scale. Dividing the iron groups into three, viz. iron, nickel, and cobalt, the chief irregularities may be summarised as follows:—The manganese and the iron groups, as well as the nickel and cobalt groups, fall nearly together, viz. 6·64, 6·82, and 7·59, 7·80, whereas the oxygen and fluorine groups, the cobalt and sodium groups, and the magnesium and aluminium groups are separated from each other by about one and a half average group intervals, viz. 5·27, 6·64, and 7·80, 9·29 and 9·82, 11·37. By assigning their mean positions to the groups, instead of the whole numbers (one to sixteen) as has been done previously, the author's empirical formula expresses very accurately the atomic weights, the chief discrepancies being found amongst the recently discovered rare elements and amongst the sulphur group. The conclusion arrived at by the author is that the atomic weights cannot be expressed by a single continuous curve, even if irregular positions are assigned to the groups.

January 29.—Mr. Francis Nicholson in the chair.—A confusion of two species of Lepidodendron (*L. Harcourtii*, Witham, and *L. Hickii*, sp. nov.) under *L. Harcourtii*, Witham, in Williamson's nineteenth memoir, with a description of *L. Hickii*, sp. nov.: D. M. S. **Watson**. In his nineteenth memoir, Williamson describes several stems as *L. Harcourtii*, Witham. Examination of these sections has shown that whilst one is probably *L. Harcourtii*, the majority belong to a type which differs from *L. Harcourtii*, Witham, in several particulars.—A collection of mammals made by Mr. S. A. Neave in Rhodesia, north of the Zambesi, with field notes by the collector: R. C. **Wroughton**.

PARIS.

Academy of Sciences, February 18.—M. Henri Becquerel in the chair.—The president announced the death of M. Marcel Bertrand, member of the section of mineralogy.—Researches on the combinations between carbon and free nitrogen: M. **Berthelot**. When acetylene is decomposed by electric sparks there is no trace of the reverse reaction, the formation of cyanogen from its elements. The author holds that there is no conclusive evidence that carbon and nitrogen combine directly at any temperature, observations to the contrary are due to the impurities in the carbon or nitrogen.—Some catalytic reactions effected under the influence of wood charcoal: Georges **Lemoine**. At a temperature of 350° C. wood charcoal causes the decomposition of alcohol into hydrogen and aldehyde. Hydrogen peroxide is freely decomposed into oxygen and water at low temperatures, and the reaction between iodic acid and oxalic acid is also accelerated by charcoal.—Remarks on the spectroheliograph: G. **Millochau**. Commenting on a recent paper by MM. Deslandres and Azambuja, the author directs attention to the spectroheliograph described by him in conjunction with M. Stefánik two years ago, and gives fuller details of the arrangement.—The theory of gases and globular clusters: H. v. **Zeipel**. An application of the theory of gases to the study of the distribution of stars in globular clusters.—A simple apparatus reproducing all the peculiarities of Foucault's experiment on the rotation of the earth: G. **Blum**.—Quasi-integral and quasi-meromorphic functions: Edmond **Maillet**.—The growth of integrals of differential equations of the first order: Pierre **Boutroux**.—The construction of a radius of curvature of the curves enveloped in the most general movement of a solid body: G. **Kœnigs**.—The variation of the vapour pressure as a function of the pressure and the determination of the ebullioscopic constants: Georges **Baume** and D. F. **Tsakalotos**.—Some molecular combinations of metallic halides with organic compounds: V. **Thomas**. The reaction between certain metals such as zinc, aluminium and magnesium is accelerated by organic substances, such as ether or alcohol. The author has made a systematic study of the various classes of organic substances capable of inducing this reaction. Besides ether and alcohol, the fatty ketones, the diketones, and nitriles all induce the reaction. The aromatic ketones, on the other hand, paraldehyde and certain aromatic aldehydes, are without effect. These effects are traced to the formation of molecular compounds of the type $CH_3CO.CH_3.MgI_2$.—Note concerning the estimation of gold by the wet method in auriferous sands: Albert **Fournier**. The presence of iron is the main difficulty in the estimation of gold in the wet way; the method described shows how this difficulty can be avoided.—The reducing and catalytic power of amorphous carbon towards alcohols: J. B. **Senderens**. Finely divided carefully purified animal charcoal was used in the experiments. At 400° C. ethyl alcohol gives ethylene and methane with small quantities of hydrogen, carbon monoxide and dioxide. With propyl alcohol, the gases contained propylene (88 per cent.), ethane, with small quantities of hydrogen and carbon monoxide. Fine sand exerts a stronger catalytic action than charcoal, and may be used with advantage in the preparation of certain ethylenic hydrocarbons. Red phosphorus at 200° C. to 240° C. induces this catalysis even better than sand.—The migration of the soluble principles in the plant: G. **André**.—

Transformations in the organism and elimination of formic acid and the formates C **Fleig**. In the intestines the formates can be converted into carbon dioxide, hydrogen, and a carbonate, chiefly by microbial action In the veins there is probably an oxidation of a diastatic nature —The brusque character of the activation of the pancreatic secretion by calcium salts C **Delezenne**.—Viviparous Diptera of the family of the Muscidæ with larvæ sometimes parasitic, sometimes vegetarian J Künckel **d'Herculais**.—Histolysis without phagocytosis, of the vibratory muscles of flight in queen ants Charles **Janet**. —The fructification of pathogenic fungi in the interior of human tissues Charles **Nicolle** and M **Pinoy** — Fundamental differences in the mechanism and evolution of the increase of resistance to infection according to the methods utilised MM **Charrin** and **Lévy-Franckel**. From experiments on rabbits it is concluded that antidiphtheric serum behaves as a drug, the effects of which pass off, as it only acts during the time of its presence, the organism remaining inert The toxin, on the contrary, causes a reaction on the part of the tissues, which, once set up, confers a new property on the cells which is more durable —Researches on the transplantation of nerve ganglions G **Marinesco** and M **Goldstein**.—Studies on the mechanism of the destruction of nerve-cells in old age and the pathological states M **Manouélian**. From the experiments given in detail the author concludes that in old age, as in pathological states, the nerve-cell undergoes similar changes In the normal state the satellite cells play an important function in the ordinary working of the nerve-cell but in old age these satellite cells exhibit a remarkable vitality, they multiply, attack the nerve-cell penetrate its interior and destroy it —The different modes of volcanic activity in the chain of the Puys Ph **Glangeaud**.—The sea floor between Madagascar, Réunion, and Mauritius J **Thoulet**.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 28.

ROYAL SOCIETY, at 4 30 — On the Dispersion in Artificial Double Refraction Dr L. N G Filon —The Occlusion of the Residual Gas by the Glass Walls of Vacuum Tubes A. A Campbell Swinton —The Theory of Correlation for any Number of Variables, treated by a New System of Notation G Udny Yule

SIR CHARLES BUNBURY.

The Life of Sir Charles J. F. Bunbury, Bart With an Introductory Note by Sir Joseph Hooker, C B, G.C.S.I. Edited by his Sister-in-law, Mrs Henry Lyell. With portraits and illustrations 2 vols Vol. i., pp x+371; vol ii, pp v+411 (London: John Murray, 1906) Price 30s. net

SIR CHARLES BUNBURY was a naturalist of the old school; his chief interest, so far as science was concerned, was in botany and geology, his published papers being almost confined to palæobotany He was an industrious diarist and letter writer, and having travelled extensively in Europe, South America, and Africa, he saw much worthy of record He had an inexhaustible interest in all that is best worth seeing and knowing, interesting people, and all the aspects of nature and art, were industriously sought out and described. But it is on the lovable personality revealed in his letters and diaries that the attractiveness of the book in large measure depends He seems to have been the most patient and even-tempered of travellers, his diaries hardly contain a querulous word He may claim the sundial's motto, "Horas non numero nisi serenas" He was fond of summing up the characters of those whom he met, and these notes, without being unduly laudatory are free from any trace of ill-nature These acute and genial sketches are, to our thinking, the best part of the book The picture which he unconsciously gives of himself is that of a man of breeding and unpretentious distinction, a man one would imagine of quiet dignity, with a simple and direct nature and an affectionate heart He observed well and described things pleasantly, his only fault as a correspondent seems to have been his lack of humour, but of this we need not complain, for there are no flat remarks intended for witticisms, nor is there anything that rings false or "smart" in his quiet, easy style

The present volumes are an abbreviation of a fuller version privately printed some years ago, unfortunately, the process of compression has not been sufficiently thorough Much as we respect and like Sir Charles, we do not want a minute itinerary of his boyish travels, though we might have liked a paragraph showing at how early an age he was alive to the beauty and interest of the world In the letters of his later life we find the same want of compression by the editor Most of us are easily satiated with descriptive letters from abroad, and there is in these volumes a good deal of this class of writing which might well have been omitted In other respects the editing of the book shows some conspicuous merits, especially in such details as biographers are apt to neglect The volumes are well printed, they are pleasantly light in the hand, and the pages are cut The date of Sir Charles's birth is given in the proper place, viz., the first line of the book, and lastly there is a full and carefully compiled index

A large number of letters are addressed to his father and to his stepmother His strong affection and respect for his father are expressed in a touching letter written in his forty-seventh year (ii, 87). After his marriage to Miss Horner, his father-in-law, Leonard Horner, his sisters-in-law, and his brother-in-law, Charles Lyell, all became regular correspondents

Lyell seems to have consulted him on botanical matters and to have written fully to him on geological questions suggested by his own researches We thus get some insight into Lyell's point of view when he was making up his mind about the "Origin of Species" and preparing for his magnanimous change of front with regard to evolution On this point Bunbury quotes (ii, 227) Sir Joseph Hooker's weighty opinion that Lyell's

"complete conversion and open avowal of his conversion to the Darwinian theory, at his time of life, and with his established celebrity, and after he had elaborately argued against the same theory in many editions of his great work, is a phenomenon almost unexampled in science"

Sir Joseph was an old friend of Sir Charles Bunbury, and botanists will read with pleasure his tribute to Hooker's genius and character (ii, 156, 226) Kingsley was another friend, and Sir Charles often records his delight in Kingsley's versatile talk and vigorous personality Kingsley must sometimes have been a little too bloodthirsty for Sir Charles Still, he quotes (ii, 266) without disapproval Kingsley's rejoicings over the victory of the Germans in the Franco-Prussian war, in which he wishes that Bunsen had been alive to see "the battle of Armageddon . fought, not as he feared, on German but on French soil"

In 1855 he paid a visit to Germany and made friends with many distinguished men Here he saw Ehrenberg, Encke, Lepsius, Jacob Grimm, "with his fine poetical head," and Ranke with his "expression of shrewdness almost of cunning rather than power" He gives (ii, 68) some account of his meetings with Humboldt, of whom he writes —

"He is a delightful old man with all the courtesy and polish of an old Frenchman, and with a vivacity and activity of mind that are perfectly wonderful in a man of eighty five He is a little bent, but still hale and fresh looking He has all the volubility of speech that I have so often heard of, but you may well suppose I was right willing to listen and did not wish to say much What is particularly striking is his eager interest in all that is going on in all the world of science, his acquaintance with all the newest researches, and his constant desire for fresh information"

Sir Charles Bunbury's letters, and especially his diaries, are of permanent interest as giving contemporary feeling about celebrated books and discoveries Thus a number of letters tell of the impression produced by the "Origin of Species" There is a curious passage (ii, 217) where he quotes with approval Lyell's surprise in 1867 at Darwin's avoidance of "any reference to a Designer" It would seem that neither he nor Lyell quite understood the Darwinian point of view

Among the numerous points interesting to botanists may be mentioned Lady Lyell's account (ii, 130) of

a visit to Robert Brown just before his death. "He talked quite calmly and cheerfully, recalling the days when he had sat in the same room in company with Banks, Solander and Dryander, and telling her *where* each of them used habitually to sit." There is, too, a striking letter (ii., 53), written apparently before Hofmeister's discoveries had reached him, in which Sir Charles argues for the connection of the Exogens with the Cryptogams by means of the Conifers, and (ii., 56) for the common nature of spores and pollen-grains.

In 1866 he noted down (ii., 214) the influences which he believed to have guided his development. Four books are mentioned:—(1) Plutarch's "Lives,"[1] which he valued as teaching magnanimity, (2) Hallam's "Constitutional History", (3) Lyell's "Principles", (4) Lindley's "Natural System of Botany." The two men of whose influence he speaks are Sir William Napier, "a great genius and a noble though singular character," and Sir George Napier, with whom he stayed at the Cape, "one of the most interesting and most profitable years of my life."

He died in 1886, aged seventy-seven; few men can have lived a long life more kindly and wisely.

F. D.

HAILEYBURY NATURAL HISTORY LECTURES.

Life and Evolution. By F. W. Headley. Pp. xvi+277; illustrated. (London: Duckworth and Co., 1906.) Price 8s. net.

THIS well-illustrated and attractive volume, according to the preface, is the final form assumed by a series of lectures delivered before the members of the Haileybury Natural Science Society, the great majority of whom are scholars at the famous Hertfordshire school. From the very nature of the case it aims, therefore, at being intelligible to readers unprovided with a large store of scientific knowledge of their own. It will be equally self-evident that it does not lay claim to be a new gospel. Rather is it an attempt, if we rightly understand its purport, to place before that section of the public which possesses a thirst for scientific knowledge a clear idea of the general structure and mutual relationships of the leading groups of animals and their adaptations to various modes of life, to show in what respects animals resemble and differ from plants, and how to distinguish between these two great primary groups of organisms, and, finally, to attempt a solution of the riddle of the evolution of organic life and of the human intellect.

The task is, of course, a heavy one, and one bristling with difficulties, but if we take into consideration the class to whom he is specially appealing and the amount of space available, we consider that Mr. Headley has come well out of the ordeal. It is not to be supposed that all his opinions will be accepted by each one of his readers, but in most cases, at any rate, he has expressed himself on debatable points with fairness and moderation, and he does not assume the character of an *ex parte* advocate. The great test of a work of this nature is whether it suits the taste of the class of readers for whom it is intended, and in the few instances in which we have been able to put this test to the proof the verdict is favourable. The style and mode of expression are almost everywhere good and interesting, and in all cases free from unnecessary technicalities, while the prevailing tone is that of a thoughtful lover of nature in all its forms. The illustrations speak for themselves.

Passing over the first chapter, which is devoted to the relationships and dissimilarities of plants and animals, attention may be directed to certain speculations in the second chapter—on the sea and its inhabitants—with respect to sedentary animals, which are regarded as having reverted to a semi-plant-like mode of existence. It is pointed out that such sedentary animals are much more numerous in the shore-waters than elsewhere. This the author believes is due to the movements of tides and currents, which bring ample food supplies without the need of any active exertion on the part of the recipients. How comes it, then, that almost all classes of sedentary animals are also well represented in the ocean-abysses, where no such free distribution of supplies takes place? The answer to the puzzle is, in the author's opinion, to be found in the fact that many of the abyssal organisms are stalked, and that they obtain nutriment by possessing the power of bending these stalks, and thus being endowed to a certain limited degree with motion. The proof that this power exists has, however, in many cases yet to be demonstrated. With regard to polyzoans and corals, the suggestion is that they may be fed by a rain of organic débris descending from the surface-waters.

Gills and lungs form the subject of the third chapter, in which reference is made to the occurrence in that hobgoblin-like fish, the Malay Periophthalmus, of an accessory breathing organ in the tail, by the aid of which the creature is enabled to spend much of its time out of water. The various phases of the respiratory function are shown to form an excellent instance of evolution, diffused breathing by the whole surface of the body giving place first of all to localised respiration by means of gills, and these again yielding to lung-breathing in the more active terrestrial forms, some of which have reverted, however, to the water, the ancestral home of all animal life.

Reptiles and their kin and the evolution of the reptile into the bird are discussed at length in the next two chapters. In seeking to find an explanation for the tendency to union between bones originally distinct, which forms such a marked feature of the avian skeleton, Mr. Headley suggests that the fusion of the tarsus with the long bones of the lower part of the legs has taken place in order to strengthen the automatic, pulley-like action of tendons which enables a bird to remain securely perched while asleep. The suggestion seems well founded. Later on we are told how the peculiar, saddle-like articulations of the cervical vertebræ enable birds to bend their necks in

[1] Fortunately for himself he read it in Langhorne's translation, so that he could peruse and re-peruse it so as almost to know it by heart. A boy of thirteen would never have got the essential good of the book if he had known it only in the original.

that supple manner which attains its maximum development in the darter, or "snake-bird" Having so carefully described this feature, it is a little surprising that the author has permitted his artist to reproduce in the plate facing p 80 the old conventional restoration of a plesiosaur with its neck bent into a swan-like curve, when, from the form of the articular surfaces of the vertebræ, it is manifestly impossible that such a flexure could have been assumed The power of neck-flexure is evidently a specialised feature due to a long process of osteological evolution

A statement on p 252 is another thing which the author on reflection would probably like to amend It is there stated that the chamæleon keeps its tongue "rolled up (the only way of pushing its monstrous length in his mouth)" This is scarcely in accord with Dr Gadow's explanation of the mechanism "The elastic part of the tongue," writes that authority, "is, so to speak, telescoped over the style-shaped copula, and the whole apparatus is kept in a contracted state like a spring in a tube"

Exception may likewise be taken to certain statements in connection with the fossil vertebrates of Patagonia on p 222 For instance, the author definitely states that the "strange hoofed animals have their nearest allies in the hyrax," whereas it is only a suggestion that one group of these ungulates might have affinity with the hyraxes, and this is discredited by Dr Andrews Again, although it may be permissible to allude to the megatherium as the megalothere, it is certainly wrong to style it the "megalothera", while to write that the seriema (not siriema) had a skull as large as that of a horse displays great want of knowledge

The author has much of interest to say with regard to the nature of feathers and the flight of birds which is one of his favourite subjects while in the final three chapters he takes into consideration the minds of men and animals, the struggle for existence, and natural selection, including under the latter heading the evolutionary theories of Darwin, de Vries, Mendel, and others To review these chapters, interesting as they are, is, however, unfortunately impossible within our allotted space We must accordingly bring this notice to a somewhat abrupt close by reiterating our opinion that the author has succeeded in producing a very readable and thoughtful book, which deserves a large *clientèle* of readers

R L

MEDICAL INSPECTION OF SCHOOL CHILDREN

The Health of the School Child By Dr W Leslie Mackenzie Pp vi+120 (London Methuen and Co, n.d) Price 2s 6d

"IN the Education Bill now [last October] before Parliament, a clause has been inserted to make medical inspection obligatory in all English State-aided schools" (p vi) "In their Scottish Education Bill of last year (1904) the Government included provision for the medical examination and supervision of school-children The examination of school-children is, therefore, no longer a question of doubtful politics. It has now all but passed into the region of administration" (p 53)

This stage having at length been reached in our own country, we can follow Dr Mackenzie with all the more readiness and interest to Wiesbaden, and listen to his account of the medical inspection of schools as he found it carried on there In this town, he tells us, there are some 10,000 elementary school-children who are under the supervision of seven specially appointed school doctors, each receiving an average stipend of about 40*l* per annum The school doctor has to examine every child when it enters and leaves the school, and during its third, fifth, and eighth school years He rejects those who are unfit for school attendance, he notifies defects to the parents, and he may give them advice as to treatment He visits the school for about an hour every fortnight in order to deal with current cases of ill-health

Dr Mackenzie describes how, on the occasion of one of his visits, he found the doctor examining thirty-five newly-entered children, observing the state of their nose, eyes, skin, bones, joints, spine, heart, lungs and the presence or absence of hernia, measuring the chest testing their speech, eyesight and hearing, and recording these various conditions on specially scheduled cards The doctor "seemed to be readily welcomed by the teachers, and was sometimes waited for by the parents, who wished to get his personal opinion of the children" (p 10)—an appreciation arguing diligent obedience to the two following regulations, which are issued in all Teutonic gravity to the school doctors "In the filling in of the particular form (notifying ill-health to the parent) all harshness and rudeness of expression are to be avoided" (p 94) "In reference to the teaching the doctor is warned that he should tactfully avoid all exposure of a teacher before his class" (p 93)

But the current of our admiration slackens when Dr Mackenzie tells us that the inspection of the thirty-five new children in the above manner occupied only an hour and a half It is difficult to believe that an examination of so wide a scope thus rapidly conducted can be of great value Practice, of course, brings speed, but not even the greatest expert could satisfactorily make such a detailed study of school children, giving an average of less than three minutes to each individual Eyesight and hearing alone could hardly be tested in that interval

"When one reflects that from twenty to thirty per cent of our school-children in Scotland suffer from eye defects needing correction or attention" (p 81), we may reasonably doubt the policy of introducing into the United Kingdom this German system of school inspection without modification

The German system should surely be modified in the direction of lightening the doctor's burden Inasmuch as "Dr Kerr, of the London County Council, found that with a little care the teachers were able to find out almost all the children that suffered from eye defects" (p 82), there is no reason why teachers should not be trained and required to test periodically

the vision and hearing of every child under their care It is manifest that "the more the teacher knows about the health of the children entrusted to him, the simpler and easier will the work of medical inspection become" (p 61) We therefore suggest cooperation between the teacher and doctor in the manner indicated

The above quotations and remarks will amply serve to show the general interest of Dr Mackenzie's little volume It is true that three of the four chapters, entitled "The Hygiene of School Life" "Normal Growth in the School Ages," "Medical Examination and Supervision of Schools and School Children," contain much that has been written of, if perhaps less attractively, before But the remaining chapter, "The School Doctor in Germany," and the appendices on "Re-vaccination of School Children in Germany" and on "The Plan of a German Elementary School," traverse comparatively unfamiliar ground, and well deserve the attention of the serious student

ELEMENTARY PHYSICS

(1) *Exercises in Physics for the Use of Schools* By J H Leonard and W H Salmon Pp vii+116 (London J Murray, 1906) Price 1s

(2) *Introductory Practical Physics* By W F Barrett and W Brown New edition Part 1 Pp xii+284 (London Simpkin, Marshall and Co, Ltd, Dublin Sealy, Bryers and Walker)

(3) *Heat, Light, and Sound an Introductory Course of Practical Exercises* By J R Ashworth Pp xv+120 (London Whittaker and Co, 1906) Price 2s net

(4) *Light for Intermediate Students* By F E Rees Pp viii+166 (London J M Dent and Co, 1906)

(5) *The Tutorial Physics* Vol iii *A Text-book of Light* By Dr R Wallace Stewart Fourth edition Revised by J Satterley Pp viii+346 (Cambridge University Tutorial Press, Ltd, 1906) Price 4s 6d

(6) *The Elements of Physics* By S E Coleman Pp vii+439 (Boston D C Heath and Co, 1906) Price 3s 6d

(7) *Physics—Theoretical and Descriptive* By H C Cheston, J S Gibson, and C E Timmerman Pp xvi+373 (Boston D C Heath and Co, 1906) Price 3s 6d

(8) *A First-year Course of Practical Magnetism and Electricity* By Dr P E Shaw Pp vii+66 (London *Electrician* Printing and Publishing Co, Ltd, n d) Price 2s 6d net

(1) A GRADUATED collection of simple arithmetical exercises in physics, including mensuration, mechanics and hydrostatics, which will prove useful for school classes No examples are given on heat conductivity Answers are furnished

(2) This text-book will be found useful for both elementary and advanced students. The volume deals with general physics, and the experiments described cover a wide range They include measurements of length, area, volume, time, and mass, experiments on fluid pressure, measurement of force, mechanical properties of solids and liquids; molecular properties of fluids The method of carrying out each experiment is briefly described, and an example is worked out in illustration Theoretical considerations are generally avoided, but many references are given to text-books or original sources, so that a student may obtain further information if he desires With such a wide range of subjects in so small a book, the treatment is often scant in places, *e g* the planimeter is dismissed without any mention of the datum circle On p 147 it is not at all clear how the mean value of Poisson's ratio is obtained from the recorded data. In the experimental proof of Boyle's law, one is told first to adjust the mercury to the same level in each limb of the tube; this very tedious operation is hardly necessary There is little meaning in the statement on p 123 that the value of g determined by simple pendulum experiments is 0 12 per cent. greater than the true value

(3) Dr Ashworth's book comprises a course of laboratory experiments in heat, light, and sound for first-year students The plan adopted with each exercise is to give a list of the apparatus necessary a short description of the method of carrying out the experiment, and a typical example to show how results are to be recorded in the note-book It is to be regretted that these examples are not always well chosen In the experiments on calorimetry, the temperature changes produced are often too small for measurement with any degree of accuracy by elementary students There is little to be gained by comparing 78·9, the determined value of the latent heat of water, with an accepted value of 79 3 when the temperature change in the calorimeter is 5° 5 C The example on the determination of the refractive index of glass, by tracing the ray through a slab, is bad Measured lengths of perpendiculars from the incident and refracted rays on the normal vary from 0·5 cm to 1 0 cm, and the mean value of the refractive index is stated as 1 52 A further illustration is afforded in an experiment to investigate the relation between the time of vibration of a spring of constant length with varying load Recorded periods are 0·54 and 0 64 second, their ratio 1 185 The ratio of the square roots of the corresponding masses is given as 1 183, and the error is stated as 0 2 per cent

(4) This little book is intended by the author for students with some previous knowledge of experimental optics The subject-matter covered, however, is very elementary, and the treatment is rather formal and meagre Two chapters, devoted to intrinsic brightness and photometry, are very clear, and will serve as a useful introduction to more advanced works on photometry Two excellent photographs of models taken with a pin-hole camera are furnished by Mr Andrew Stephenson, and a graphical proof of the minimum deviation position is due to him Lens and mirror formulæ are derived in the ordinary way The curvature method for obtaining these formulæ is not introduced, and no mention is made of the term "power of a lens" The book is attractive in appearance, and many students will probably find it useful for revision purposes

(5) The revised and enlarged edition of Stewart's "Light" contains a very full treatment of the elements of geometrical optics The inclusion of a large number of simple practical experiments enhances the value of the volume considerably Dispersion and spectrum analysis receive a fuller treatment than in the previous edition The book will prove distinctly useful.

(6) An introductory text-book of theoretical physics, the subject-matter having been selected with reference primarily to its value as part of a general education Problems are interspersed at frequent intervals, and some of these are well designed to make a student think A great deal of care has been exercised in the compilation of this book

(7) This text-book of physics, which includes mechanics, heat, light and sound, electricity and magnetism, has been written for pupils in the American high schools. The statements are concise, and the diagrams clear It is thoroughly up to date, and will prove a very suitable introductory course, especially if, as the author intends, laboratory work is carried out at the same time

(8) The author in his preface intends this book for that class of technical students who are ignorant of the rudiments of algebra, geometry, trigonometry, and mechanics The book includes three introductory exercises, six exercises on magnetism, and twenty-six on current electricity and its applications There is very little in the method of treatment to distinguish it from other elementary text-books of practical electricity and magnetism It is doubtful whether a student will draw a correct idea as to what determines a spark in air from the statement on p 30 —

"Join 1 ft. of copper wire to one terminal (of a Leclanche cell) and brush the other terminal with the free end of the wire No spark is seen because the E M F of the cell is only about 1 3 volts and the resistance is high, so the maximum current is very small"

And on p 32 (repetition with storage cell) —

"The E M F is about 2 volts, and the resistance is very small, so the maximum current is large Sparking is abundantly shown"

No thoughtful teacher would instruct a student to count the number of vibrations a magnet makes in a given time, as in the experiment described on p 13 Elementary electrostatic experiments are omitted, as these are thought to be relatively unimportant and difficult. There is little to recommend this book when compared with some excellent introductions which have appeared in recent years

OUR BOOK SHELF

Animal Artisans and other Studies of Birds and Beasts. By C J Cornish Pp xxxiv+274, illustrated. (London Longmans, Green and Co, 1907) Price 6s 6d net.

THE late Mr. Cornish was a constant contributor of articles bearing upon natural history matters to the columns of the *Spectator* and *Country Life*; and the present volume, which is edited by his widow, consists mainly of a reprint of articles from those journals, with such modifications as the course of time has rendered necessary or advisable In some cases the articles had been revised with a view to publication in book form by Mr. Cornish himself, but where this had not been done in the author's lifetime the task devolved upon the editor.

The volume opens with a brief account of the life of Mr Cornish, which will no doubt be welcome to the numerous readers who find entertainment or instruction in his works Following this are several articles, upon which the title of the volume is evidently based, some of these dealing with the works of such birds as the South American oven-bird and our own woodpeckers, while "road-making animals" and "landscape-gardeners" form the subjects of others Several of these articles display a lamentable want of knowledge of scientific zoology on the part of the author We are told, for instance, on p. 34, that "the musk-ox, the *ovibos*, is as much akin to the sheep as to *bovidae*, and in habits more like what we imagine the undescended great wild original of our sheep was than are the wild sheep of to-day" In regard to the first half of the sentence, it is now accepted that the musk-ox is not a near relative of either sheep or oxen, while the whole group is included in the Bovidæ. As to the meaning of the second half of the sentence, we are altogether in the dark Again, on p 48 we notice the astounding information that the pampas stag is the only large ruminant on the plains of South America, which, by the way, are stated to be formed of clay Other similar cases might be cited, but in the case of a posthumous work criticism must not be too trenchant, and, after all, the volume is perhaps sufficiently accurate to suit the requirements of the readers to whom it is likely to appeal

Rubber in the East Being the Official Account of the Ceylon Rubber Exhibition held in the Royal Botanic Gardens, Peradeniya, in September, 1906 Edited by Dr J C Willis, M Kelway Bamber, and E B Denham Pp 269, illustrated (Colombo H C Cottle, Government Printer)

THIS interesting and up-to-date work is the official account of the Ceylon Rubber Exhibition held in the Royal Botanic Gardens, Peradeniya, in September, 1906 (see NATURE, December 27, 1906, p 209) The duration of the exhibition allowed of its being a Rubber Congress, lectures being given upon the various branches of the subject from cultivation to vulcanisation These lectures, discussions, judges' reports, &c, have been brought together in the present volume and arranged in a logical order with the hope of making this account a standard treatise upon the rubber industry as it at present exists

The chapters dealing with the cultivation of rubber in Ceylon and other countries, treatment of diseases, tapping knives, machinery for the treatment of latex, and the shipment and marketing of rubber, should prove valuable aids to the practical rubber grower

Some idea of the rapid growth of the industry is gathered when we see that five years ago there were only 2500 acres under rubber in Ceylon, and to-day 104,000 acres, the *Hevea brasiliensis* being the species most extensively planted This tree produces the well-known Para rubber, which, prepared in the ordinary way, possesses 90 to 95 per cent of caoutchouc The Hevea appears to stand tapping operations even when of a very drastic nature

High tapping has been tried on some plantations up to 30ft and 50ft, and this system gives in some cases 12lb to 14lb of rubber per tree, but there is

a curious phenomenon in connection with this high tapping, viz., the frequent difficulty of coagulating the latex.

One lecturer, Mr. J. B. Carruthers, deals with the possibility of rubber for pavements for roadways, and mentions the rubber pavement under the archway leading to Euston Station, which was laid down in 1881. In 1902 the pavement was found to have worn down to ⅜ of an inch in the thinnest places. This rubber pavement cost less than three times as much as wood or asphalt, but the life of wood or asphalt was four years, and the life of a rubber pavement twenty years. The book is well illustrated throughout, and there are some interesting maps of Ceylon, Perak, &c., showing lands under rubber or alienated for rubber. L. C. B.

Some Modern Conditions and Recent Developments in Iron and Steel Production in America. By Frank Popplewell. Pp. x+119. (Manchester University Press, 1906.)

THIS report contains an account of a visit to the iron and steel-producing centres in the United States from September, 1903, until April, 1904, made by the author as Gartside scholar of the University of Manchester. It comprises an introductory sketch of the metallurgy of iron and steel, some general considerations on the extent of the American industry, and descriptions of the raw materials used, of the production of pig iron, and of the manufacture of steel and of rolled steel products, and, lastly, some notes on American labour and education.

The author employed his time well, and has given a clear idea of modern conditions. The important subjects of the Steel Trust, organised labour, and railway transport are not touched upon, and the report suffers from the disadvantage that progress is so rapid in America that in the interval that has elapsed between the visit and the publication of the report many important changes have been effected which have rendered some of the information collected antiquated, and much of the interest has been impaired by the publication of reports by later visitors, notably in the German work by Dr. H. Levy, and in papers written by members of the Iron and Steel Institute who took part in the New York meeting of that society. Thus there is no mention of the most interesting novelty in blast-furnace practice, namely, Mr. Gayley's desiccation of the blast by a preliminary chilling of the air before its admission to the cylinder of the blowing engine, nor does the index refer to the Talbot continuous steel-making process which, first used at Pencoyd, has proved surprisingly economical in this country. Mr. Popplewell gives, however, a clear exposition of the results of specialisation in production, of the development of ore-handling machinery, and of the general use of the charging machine, features that characterise American practice. He shows, too, that the colossal blast furnace with huge yield due to high-blast pressure, regardless of consumption of steam and boiler coal, is giving place to a blast furnace of more modest dimensions, with a maximum height of 80 feet or 85 feet, for the treatment of fine ores.

The impression derived from reading Mr. Popplewell's report is that many of the most striking developments, admirable as they are, were designed to meet special wants, and are not necessarily applicable in Great Britain. Thus, to give one example, the enormous stock piles called for by the intermittent navigation of Lake Superior are not required in districts where supplies arrive continuously throughout the year.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

The Positive Charge Carried by the α Particle.

IN a letter in NATURE (August 2, 1906) I gave an account of some experiments which I considered proved that the α particle as initially expelled is not charged, and I also gave an account of the same work in a paper read before the British Association at York last August. Although I have no reason to doubt the accuracy of the experiments published in my letter, I do not now consider them sufficiently conclusive, as some recently published researches on the α particle have to be taken into account in their interpretation. I refer chiefly to a paper published by Rutherford shortly after my letter (*Phil. Mag.*, October, 1906, p. 348), in which the view is put forward that the α particle carries two atomic charges.

Now the reasoning in my letter was based on the assumption, then held universally, that the charge on the α particle was the indivisible single atomic charge, and it was not necessary at that time to contemplate the possibility of any intermediate condition existing between the α particle charged and uncharged. But it is clear that if, as Rutherford considers probable, the α particle carries a multiple charge, the results I published in my letter do not by themselves suffice to prove that the α particle as initially expelled is uncharged, for it might possess a fraction of its final charge initially, obtaining the remainder and becoming correspondingly easier to deviate magnetically in its passage through matter. This is, of course, a contingency not contemplated in my original conclusion.

I had hoped long ere this to submit this point to an experimental test, which is simple enough to do by varying the strength of the field. But I very much regret I have no longer the essential facilities necessary to carry on the investigation, particularly the means of obtaining a steady supply of liquid-air, and there does not appear to be any immediate prospect of my being in a position to repeat the experiments. The question at issue is a somewhat fundamental one in the relations of electricity and matter, and of course, cannot be finally settled by any one series of experiments, but only after long-continued and frequently verified observations. But I can neither continue the investigation nor even repeat the experiments I have already made, so nothing remains but to withdraw what I have already published. FREDERICK SODDY.

The University, Glasgow, February 26.

The Rusting of Iron.

IN NATURE of February 21 (p. 390) appears a letter from Prof. Wyndham R. Dunstan in which he represents me as having concluded "that carbonic acid is essential to the rusting of iron, and that rusting does not occur in its absence." As such a general statement, without reference to the context of the paper to which Prof. Dunstan refers, may prove misleading, I shall be obliged if you will allow me to point out that the main and incontrovertible conclusion drawn from experiments extending over a prolonged period is that iron does not undergo oxidation in presence of oxygen and water. If, however, a minute quantity of acid (either carbonic acid or *any other acid capable of attacking iron*) be present, the metal is first converted into ferrous salt, which subsequently oxidises to rust. Samples of iron which contain such impurities as sulphur, phosphorus, and carbides may give rise to free acids when in contact with water and oxygen, and under these conditions rusting may be expected to occur, even if carbonic acid be rigorously excluded.

Prof. Dunstan does not inform us if he adheres to his definitely expressed views "that iron, oxygen, and liquid water are alone necessary for the rusting of iron to take place," and that "hydrogen peroxide is a necessary intermediate product of the chemical change involved in rusting," but he confines himself to stating again that acid potassium chromate, a substance which destroys hydrogen

peroxide, inhibits rusting He ignores the fact that there are other substances, such as potassium iodide, which immediately destroy hydrogen peroxide and yet do not inhibit the rusting of iron Moreover, if Prof Dunstan's assumption that substances which destroy hydrogen peroxide (which he regards as an essential initial product of rusting) inhibit rusting be accepted, it will be necessary to admit, contrary to the general experience of chemists, that the presence of a substance capable of removing one of the products of an action does not accelerate the action, but actually prevents it

Prof Dunstan does not say in what respects his experiments on the oxidation of iron have afforded results differing from my own, but I may remind him that only after repeated failures was I successful in bringing together iron, oxygen, and water, and in avoiding the presence of acid

GERALD T MOODY

Central Technical College, February 22

The Valparaiso Earthquake, August 17, 1906

PROF MILNE'S note in NATURE of February 21 raises an interesting question which can readily be answered, the earthquake which preceded the Valparaiso shock originated under the North Pacific Ocean in about 30° N lat, 170° E long, at about 0h 11m a m G M T, or 35½ minutes before the Chilian earthquake as recorded at Santiago This position does not agree with the distance given in the note, but Prof Milne in correspondence, has informed me that this is in error, and the distance, as indicated by the Shide diagram, is 90°, which is in close accordance with my own determination of the distance

It must be remembered that all attempts at deducing the distance of origin from a single seismogram are necessarily approximate, though the error will probably be within 5° of arc, or about 350 miles, in the case of a great earthquake giving a complete record The determination of the place of origin becomes easy when a sufficient number of records from widely separated localities are available and these are at my disposal for seeing that the Chilian earthquake was likely to be an important one in connection with an investigation on which I was engaged I wrote to a number of seismological stations the addresses of which were known to me, and met with a most generous response to my requests Unfortunately, when the copies of seismograms came in it was evident that they recorded two earthquakes, of which the earlier was of unknown origin the record of which in every case overlapped that of the Chilian one, and rendered the latter practically useless

R D OLDHAM

Nomenclature of the Proteins

IN the current number of the Proceedings of the Chemical Society, the council has issued some valuable proposals for change in the nomenclature of the proteids and allied substances While not venturing to criticise the majority of the recommendations I notice a definition in the proposed subclass 5 which appears to me slightly inaccurate The subclass in question reads as follows —

"5 Sclero-proteins This new word takes the place of the word albuminoid in the limited sense in which the majority of physiologists have been accustomed to use it It includes such substances as gelatin and keratin, the prefix indicates the skeletal origin and often insoluble nature of its members"

Now, it seems to be a generally accepted view that gelatin does not exist ready-formed in nature but results from the hydrolysis or hydration of collagens (v Allen's "Organic Analysis" vol iv and Cohnheim's "Chemie der Eiweisskörper") Is not gelatin as much a product of protein hydrolysis as acid-albumin or alkali-albumin, for which the generic term meta-proteins is now proposed? Would it not, therefore, be preferable to reserve the term sclero-proteins, in its strictest sense, for the wholly insoluble products of animal-cell activity such as chondrigen, ossein, sericin, and keratin, and class their hydration-products such as gelatin and silk-gelatin among the meta-proteins?

The committee apparently sees no objection to including gelatose among the proteoses

W S GILLES

Bocking, Braintree Essex March 4

Maximum Gravitational Attraction on a Solid.

CAN you tell or refer me to the solution of the following question —

What will be the shape of a definite quantity of mass of given specific gravity in order to obtain maximum gravitational attraction at a point on its surface? I have tried various shapes of equal volume, including square and rectangular figures, hemisphere, sphere, and cones For these shapes I found that the maximum attraction obtained at the centre of the base of a cone the apex angle of which was about forty degrees, no doubt the frustrum of such a cone would attract with greater force

This question is no doubt of academical interest only, but the solution should be instructive from certain points of view

W E MILLER

Publication Bureau, General Electric Co, Schenectady, New York, U S A

THE solid is one of revolution (evidently), and the attraction being a maximum is unaltered by shifting a small elementary ring of matter from one point to another of its bounding surface If dM is the mass of a ring formed by the revolution of the point r, θ, then the attraction is $dM\cos\theta/r^2$ Hence the equation of the generating curve of the boundary is $\cos\theta/r^2=\text{const}$, or $r^2=k^2\cos\theta$ say or $(x^2+y^2)^3=k^4x^2$ The curve may be traced by drawing the circle $r=k\cos\theta$ and taking on each radius vector a mean proportional between that radius and k

According to this result, the form of the bounding curve for a surface of revolution is the same as it would be for a plane lamina possessing the same property The agreement can be justified by taking a thin slice through the axis of the solid The matter contained in this slice must evidently be arranged in such a form as to give the maximum attraction independently of the remaining parts of the body

G H BRYAN

A New Chemical Test for Strength in Wheat Flour

THE test described as new by Mr Wood in NATURE of February 21 has been in use in my laboratory during the past year, where it forms part of the regular routine tests applied to flour While I am fully in agreement with Mr Wood's view that the volume of carbon dioxide evolved by a mixture of yeast and flour under standard conditions is a measure of the sugar content of the flour together with other fermentable matter produced during the fermentative change, it is important not to lose sight of the influence exercised by the character of the gluten on the volume of the loaf A rotten gluten when distended by too much gas will break, and the gas will escape from the dough From this point of view the character of the gluten is clearly of fundamental importance but after all, the problem is one in which no small number of variables must be dealt with

E FRANKLAND ARMSTRONG

A Remarkable Lunar Halo, February 24.

IN NATURE of May 1, 1902 (vol lxvi, p 5), a remarkable lunar halo was described as having been witnessed from the Yerkes Observatory on January 19, 1902 It consisted of an ordinary lunar halo, of 45° or 50° in diameter, and of a second ring approximately the same in size intersecting the first, and cutting exactly through the moon

The same phenomenon was very clearly seen by myself and others at Pembroke Dock during the evening of Sunday, February 24, between 9 p m and 10 p m The secondary ring appeared to be about a third as large again in diameter as the primary, and was situated approximately to the north-east of it In both rings the brownish tinge of the edges and dark interiors were perceptible, though very much more strongly in the primary than in the secondary

I should be glad to know whether any explanation has yet been advanced as to the optical formation of the secondary ring in the above rare phenomenon

A PRACTICAL HANDBOOK OF BURMA[1]

SIR GEORGE SCOTT has condensed into a volume of 485 pages, which any tourist can conveniently carry about, a mass of useful information about Burma. The book is described in the preface as of the nature of a skeleton or of a painter's study for a larger work. It is, however, much more than this, and contains all that any ordinary tourist needs to know about Burma, and, indeed, a good deal which is not known even to some who have resided for many years in Burma.

The work is divided into seven parts. Part i., "The Country and Climate," contains, besides an account of the fauna, flora, and geology and minerals of the country, a most interesting account of the races of Burma.

It is doubtful who were the original inhabitants of Burma. The only aboriginal tribe of which there is any trace are the Selungs, who live in the islands of the Mergui archipelago. Their language shows affinities with those of the Tsiam or Cham aborigines of Cambodia and of the Ætas or Negritos, aborigines of the Philippine Islands. In any case, the aboriginal inhabitants have been almost entirely replaced by swarm after swarm of Indo-Chinese invaders who have come down from north-western China, from Tibet, the Pamirs, and Mongolia, following the course of the great rivers. The Indo-Chinese were followed by the Tibeto-Burmans. After the Tibeto-Burmans came the peoples of the Siamese-Chinese sub-family—the Karens and the Tai, or Shans, and the last irruption, that of the Chingpaw, was only stopped by the British occupation of the country. The people of Burma, although they are divided into many tribes and races, are, with the exception of the Selungs, all of the same original stock. Out of the total population of Burma, which was found at the census of 1901 to be approximately ten and a half millions, about seven millions speak Burmese.

Sir George Scott gives an account of all the various races found in Burma, and illustrates his text by photographs of many of them. We here reproduce the frontispiece photograph of the stiff-necked Padaung belles. These women wear neckbands of solid brass rods. The bands vary in number from five to twenty-five, and the idea with which the bands are worn is to keep the neck always on the stretch. Five coils are all that can be got on to begin with, but fresh coils are added as space is made for them as the girl grows, so that the neck is constantly kept at the stretch until the full limit of twenty-five bands is reached. Similar coils are worn on the legs and arms, so that the average woman carries fifty or sixty pounds of brass, and some manage as much as eighty pounds. Thus weighted, they carry water for domestic use, hoe the fields, and go long distances to market.

FIG. 1.—Stiff-necked Padaung Belles. The neckbands of these women are of solid brass rod. They vary from five coils to twenty-five. From "Burma: a Handbook of Practical Information."

Part ii. contains an account of the Government of Burma. The first provinces of Burma to be annexed were Arakan and Tenasserim after the first Burmese war in 1826. The province of Pegu was added in 1852, after the second Burmese war, and Burma, as it now stands, was completed by the annexation of Upper Burma after the third Burmese war of 1885–1886.

The three provinces of Arakan, Tenasserim and Pegu were administered each by their own Commissioner under the Governor-General of India until 1862, when they were amalgamated under a Chief Commissioner, and it was not until May 1, 1897, that Burma became a Lieutenant-Governorship.

The account given of the duties of officers is generally correct, but since the handbook was written commissioners of divisions and deputy commissioners of districts in divisions and districts where work was heavy have been relieved of judicial duties by the appointment of divisional and district judges, whose time is devoted entirely to judicial work.

In this part Sir George Scott gives an excellent account of the Shan States, with which he is so intimately acquainted. The progress made in the Shan States, which were in a state of complete anarchy when Upper Burma was annexed, is surprising. All that they now require to secure their further development is the Southern Shan States railway, which will, it is anticipated, soon be commenced. Accounts are also given of Karenni, the Kachin Hills, and the Chin Hills. The Northern and Southern Shan

[1] "Burma: a Handbook of Practical Information." By Sir J. George Scott, K.C.I.E. Pp. x+520. (London: A. Moring, Ltd., 1906.) Price 10s. 6d. net.

States, Karenni, the Kachin Hills, and the Chin Hills are all administered by special officers under regulations which are suited to the primitive condition of the people

The subject of education is also dealt with in this part It is remarked that there is no province in India which can compare with Burma in the number of the population able to read and write The fact that primary education is so widely diffused is due to the indigenous schools Every monastery is a school, and there is a monastery in almost every village Education is free, and there are no caste restrictions in Burma There every Buddhist boy learns at least to read and write

Part ii concludes with a history of Burma from the earliest times The history is as complete as it is possible to make it in 38 pages An authentic photograph of the ex-King Thibaw and the ex-Queen Supaya-Lat, who are now detained at Ratnagiri, an old Portuguese fort on the west coast of India, is given at p. 200 of the handbook

FIG 2.—Wa Suspension Bridge From "Burma a Handbook of Practical Information.

Part iii deals with industries, the forests of Burma, mines, agriculture, trade, transports, currency, weights and measures. All these subjects are dealt with exhaustively, and this part will well repay perusal.

The subjects discussed in part iv are archæology, architecture, art, and music Burma is called the land of pagodas, and Sir George Scott points out that there are three distinct types of religious buildings—the solid pagoda enshrining relics, the carved and ornamented wooden monasteries, and the masonry temples The most celebrated temples are in the ruined town of Pagan Many pagodas are in ruins because, except where the founders have endowed them, and thus assured their preservation it is to nobody's interest to preserve a pagoda The merit of erecting a pagoda is great, but the merit attaches to the original builder, and not to the restorer or repairer

The Government provides for the maintenance of some of the most notable pagodas, and for others there are trustees, who administer the endowments and collect the offerings of the faithful, and spend the proceeds on the repair of the buildings, but ruined and deserted temples are to be seen all over the country

Part v is taken up with an account of the Buddhist religion which is very complete As Sir George Scott states, there is no doubt that the original religion of Burma was animism, and that this form of religion still survives amongst the vast body of the people Buddhism, as many consider, is not a religion at all, but a system of philosophy What most Burmans really reverence are the spirits of the air, the mountain and the fell Many of the hill tribes are spirit worshippers pure and simple Serpent worship too, still survives

Part vi is devoted to language and literature We are sorry that space does not permit us to give any extracts from this part

Part vii concludes the handbook with some useful hints to residents or new visitors, and the last paragraphs of this part tell the readers something about sport

There are also three appendices The illustrations are numerous and good. We reproduce as a sample the photograph of a Wa suspension bridge

In conclusion, we strongly recommend every intending visitor to Burma to provide himself with a copy of this handbook, in the compilation of which Sir George Scott has shown that he has a thorough knowledge of the country, to which he has added much industry and research

We think that the handbook, besides being indispensable to the tourist, is also well worth perusal by members of the non-travelling public who are anxious to know all that can be told about one of the most recent, and at the same time most interesting, possessions of the British Crown

PROF MARCEL BERTRAND

IT was with deep regret that English geologists learned that Prof Marcel Bertrand, professor of geology at the French National School of Mines, died on Wednesday, February 13 Born in Paris on July 2, 1847, a member of a family of great mathematicians, he inherited a natural gift for the exact sciences, and especially for geometry, which enabled him to enter into l'École Polytechnique in 1867 In 1869, owing to his brilliance as a student, he was selected by the French Government as mining engineer For three years he attended the courses of Élie de Beaumont and others at the School of

Mines This teaching decided the direction of his life's work along the traditional lines of the school of which he was in turn a student, an instructor, and one of the most distinguished professors from the year 1886

It is a special feature of the French Geological Survey to avail itself of the help of outside professional geologists, such as university professors and teachers, by engaging them during the summer holidays as auxiliary collaborateurs It is in that way that Marcel Bertrand was induced to carry out during the summer months of several years a series of field observations in the Jura mountains, with the view of publishing detailed geological maps of the region It was quite natural that the growing interest of the young geologist was excited by the structure of this district - classical for the relative regularity of its foldings

In 1881 Bertrand was led in the same way to investigate the geology of Provence, where a simple appearance hides extreme complexity of structure It was there that, after several occasional visits to the Alps, he was able to bring new light to bear on the earth's anatomy He was the first to perceive that the foldings of the pre-Alps have been altered in depth by the older horst of Maure Mountains, and have resulted in extensive overfoldings which later on have been again obliquely plaited by more recent compression These investigations culminated in 1887 in the publication of his "Memoire sur le Beausset (Var)," which, notwithstanding its shortness and local character was received with keen interest by Continental geologists It was for them the starting point for further inquiries upon new forms of disturbances, and especially upon those long recumbent folds the horizontal extension of which is so great that they are frequently spoken of as sheets

Bertrand's great experience of the coal mines of the north of France afforded him the opportunity of detecting that overthrusts of the same amplitude had taken place at the close of the Carboniferous period He expounded these similarities in his memoirs upon "Les Rapports de Structure des Alpes de Glaris et du Bassin Houiller du Nord," where it was suggested, for the first time, that the famous dopple fold of Glaris might be regarded as a single exaggerated overfold coming from the south This explanation is now accepted by Prof Heim himself

In 1896 Bertrand wrote a preface to introduce to the French public a translation of Suess's "The Face of the Earth" If anyone should deny to scientific men the gift of expressing their ideas in a concise and adequate style, reference should be made to this brilliant and lucid account of the progressive development of structural geology from the first attempts of Leopold de Buch and Élie de Beaumont to the synthesis of Suess involving the whole surface of our planet, or the minute re-construction of the former orography of the Highlands by Prof Lapworth

In 1896 Bertrand was elected a member of the Académie des Sciences to fill the chair left vacant by the death of Pasteur In 1900 he took a large part in the organisation of the Paris meeting of the International Geological Congress He contributed two papers on the geology of the Western Alps, and personally directed one of the excursions in that district It was the last gratification of his life, for shortly after he suffered great affliction by the death of his daughter, who was buried by a sand-slip when geologising with him

It is deeply to be regretted that such a gifted man has passed away without having fulfilled his possibilities. He scattered some of his original ideas in short papers which appeared from 1884 until 1900, chiefly in the *Comptes rendus* of the French Academy of Sciences, in the *Annales des Mines*, and in the Bulletin of the Geological Society of Paris. But he did not concentrate his abilities upon a great scientific work which might have been compared to the volumes by Prof Suess Our only consolation is the power he possessed to impart his spirit to his students and to the number of his disciples, such as MM de Launay, Lugeon, Termier, Caveux, Ritter, &c, whom he left behind fitted to carry on his work

M M ALLORGE

H C RUSSELL, C M G, F R S.

THE announcement of the death of Mr H C Russell, who for nearly forty years was among the foremost representatives of science in the colony of New South Wales, has been received with great regret by many men of science Since 1870 he held the post of Government astronomer and director of the Sydney Observatory, in succession to Mr G R Smalley, and in that capacity rendered most important services to the colony His first duty on appointment was to organise the resources of the colony for the observation of the transit of Venus With small funds, little skilled assistance, and short time for preparation, he nevertheless succeeded in equipping several stations in a highly efficient manner, reflecting great credit upon the readiness of the colonists and the exertions of the observatory staff

Thenceforward the observatory pursued a course marked by continually increasing usefulness, culminating in the acceptance of a share in the international photographic chart of the heavens The zone allotted to this observatory extends from $-52°$ to $-64°$ declination, and under Mr Russell's direction the task advanced far towards completion But in the course of the work it was found that considerable improvement might be effected if the telescope were removed to a station remote from the town of Sydney The director had long advocated the removal of the observatory, and the mounting of the photographic equatorial at Red Hill probably presages the abandonment of the Sydney site The measurement of the plates is being prosecuted on a common plan with those taken at Melbourne, and one of the latest papers from Mr Russell has reference to an improved form of micrometer for the measurement of these plates Mechanical devices always had great interest for the late director, and he paid great attention to special forms of driving clocks for equatorials

But most of all the colony is indebted to him for his organisation of the meteorological service. He had charge of a district of the climate of which little was known, and as the colony extended and the population occupied areas of unexplored country, he had to widen the range of his inquiry in order to supply the necessary information to intending settlers The long series of observations that he published on climate factors, especially those having reference to rain, evaporation, and state of the rivers, attest to his industry, his powers of organisation, and his recognition of the requirements of a young and rising colony He put it on record that when he assumed office there were but five rain-gauges in the colony On his retirement there were something like two thousand His discussion of the results has scarcely been as happy as his collection He seems to have relied upon statistical methods rather than on physical facts, and in this way was led to suggest a theory which would make the

amount of precipitation depend upon the moon's nodes These cycles are shown very distinctly over the few years that he was able to bring under discussion, but his explanation has not been generally accepted This is a small matter in comparison with the value of the information which he was able to furnish, and which has contributed in no small degree to the prosperity of the colony. This collection of observations will be of the greatest service in subsequent inquiries

Mr Russell has left a character for industry and closeness of application that cannot but prove stimulating to future astronomers in the southern hemisphere. He was much esteemed by many friends in this country, who regretted his retirement from the observatory, and besides being a Fellow of the Royal Society, to which he was elected in 1886, he was a member of many learned bodies, and was well known as a contributor of frequent and welcome papers

W F P

DR ALLAN MACFADYEN

BACTERIOLOGICAL science in England has sustained a great loss by the early death of Dr Allan Macfadyen, who passed away on March 1 a martyr to that science he loved so well and to which he had devoted his best days, his last illness being caused by accidental infection in the laboratory

Dr Macfadyen was a distinguished graduate of Edinburgh University, and subsequently studied at Bern, Göttingen, and Munich One of his earliest investigations was on the behaviour of the bacteria in the digestive tract, in which he proved that the gastric juice and intestinal secretions protect but little against the invasion of pathogenic microbes This was soon followed by a joint paper with Prof Nencki and Dr Sieber, on the chemical processes occurring in the small intestine of man in which the intestinal contents were examined and the exact chemical changes produced by several intestinal microorganisms in pure cultures were studied With Sir Lauder Brunton, an investigation of the ferment action of bacteria was contributed to the Proceedings of the Royal Society, and his chemical bent was further shown by a paper on the action of bacteria on albumins and peptones, which appeared in the Reports of the Local Government Board The thermophilic bacteria, organisms which thrive at high temperatures, attracted his attention, and with Dr Blaxall he carried out an investigation on them in which, almost for the first time, a number of species were differentiated and their action studied With Dr Harden, Mr Rowland, and the late Dr Morris, researches were conducted on the nature of the yeast zymase of Buchner, and the phosphorescent bacteria and problems of disinfection were other subjects in which he made additions to our knowledge

Dr. Macfadyen was early inspired with the idea of the paramount importance of the contents and extracts of the unit of life—the cell—and the happy culmination of Sir James Dewar's researches on low temperatures gave him an unlooked-for means of obtaining these in a comparatively unaltered state He showed that the low temperatures of liquid air and of liquid hydrogen had little or no effect on either the vitality or the functions of microorganisms With Mr Rowland he attacked the problem of grinding up bacteria with liquid air, and by a number of ingenious devices he finally succeeded in obtaining the juices of bacteria in sufficient quantity for investigating their characters The comparative failure of attempts to produce therapeutic sera for such diseases as tuberculosis, typhoid fever, cholera, pneumonia, &c, the organisms of which produce little or no extra-cellular toxins, suggested that the juices of these organisms, the "endotoxins," obtained by liquid-air grinding, might be used for immunising He showed successively that the virulence of an organism varied directly with the amount of endotoxin that could be obtained from it, that an animal might be immunised by means of these endotoxins, and that the serum of such an animal possessed immunising and curative properties

The application of these principles to the typhoid bacillus, cholera vibrio, pneumococcus, and hog-cholera bacillus was described in a series of papers Latterly, the application of the results to the treatment of human disease occupied Dr Macfadyen's attention with encouraging prospects, and it is a tragic circumstance that he should be cut off just as his life-work seemed to be nearing completion

As secretary and head of the Bacteriological Department of the British, Jenner and Lister Institute of Preventive Medicine, as it was successively named, Dr Macfadyen had a large share in the organisation of the institute at Chelsea, and much of the bacteriological work that emanated from there was inspired by him As Fullerian professor of physiology at the Royal Institution 1901–4 his courses of lectures on the cell, antitoxins physiology of digestion, and other subjects made him known to a wide circle

R T H

NOTES

THE following candidates were selected on Thursday last by the council of the Royal Society to be recommended for election into the society —Frank Dawson Adams Hugh Kerr Anderson, William Blaxland Benham Lord Blythswood, William Henry Bragg Frederick Daniel Chattaway, Arthur William Crossley Arthur Robertson Cushny William Duddell Frederick William Gamble John Ernest Petavel Henry Cabourn Pocklington Henry Nicholas Ridley Grafton Elliot Smith and William Henry Young

PROF W A TILDEN F R S has been elected a member of the Athenæum Club under the provisions of the rule of the club which empowers the annual election by the committee of three persons "of distinguished eminence in science literature the arts, or for public services"

A DEPUTATION representing the Anthropological Institute, the British Science Guild and other scientific bodies waited upon the Prime Minister on Tuesday to urge the establishment of a national anthropometric survey Mr R C Lehmann, M P who introduced the deputation said that, in the first instance the survey should have for its object the periodic measurement of children and young people in schools and factories Besides this, a comprehensive survey of the general population of the whole country should be undertaken The sum asked for is 4000*l* or 5000*l* The need for such a survey was described by Dr D J Cunningham, Mr J Gray Dr Gow Sir Lauder Brunton and Dr A C Haddon In his reply to the deputation Sir Henry Campbell-Bannerman confessed that he has been much impressed by the arguments adduced as to the great lack that there is in this country of knowledge of the quality of the population It is obviously desirable to have a record of the kind proposed in order to be able to study the changes in the condition of the people at large as a guide to action in administration and in legislation regarding it Any test applied to the condition of the inhabitants of any district is a test of their surroundings, of the mode in which they live.

and the circumstances which affect their health and utility and therefore this cannot be an unimportant thing It is very desirable to avoid any impression that a sort of experiment is to be practised upon the poor children in the common schools Whatever is done to the poor ought to be done also to the rich, and the application of the system ought to be universal In fact, it will cease to have its proper value if it is confined to the poor schools, which are a little more at the disposal of the Government and the authorities than the great schools, such as Westminster and others. Results are wanted referring to the whole population, so that comparison may be made between different districts and different occupations The sum mentioned for the survey is a modest amount, but a great many modest sums make up a large sum But the mere question of cost is not likely to stand in the way of a great scheme of this sort if the Government is satisfied on full consideration—which shall be given to it—that the time is ripe for this new enterprise

THE Goldsmiths' Company has contributed the sum of 1000*l* to the research fund of the Chemical Society

THE 134th anniversary dinner of the Medical Society of London will be held on Wednesday, March 13, at the Whitehall Rooms, Hotel Metropole

THE death is announced of Mr C A Witchell, author of "The Evolution of Bird Song, with Observations on the Influence of Heredity and Influence," and of other works on natural history

A MEETING of the Institution of Naval Architects will be held on March 20–22 At the opening meeting Lord Glasgow, president, will deliver the presidential address, and the gold medal of the institution will be presented to Prof R L Weighton

THE *British Medical Journal* states that the Portuguese Minister of Marine has decided to send a scientific mission to the Ilha do Principe, in the Gulf of Guinea, for the purpose of trying the effect of measures of general prophylaxis against sleeping sickness, the prevalence of which on the island continues to increase

ON Thursday next, March 14, Dr C W Saleeby will begin a course of two lectures at the Royal Institution on "Biology and Progress" The Friday evening discourse on March 15 will be delivered by Prof Lunge, on "Problems of Applied Chemistry," and on March 22 by Prof J J Thomson, on "Rays of Positive Electricity"

AT the meeting of the Anthropological Institute to be held on March 12 in the theatre of the Civil Service Commission, Burlington Gardens, W, Dr C G Seligmann will exhibit a series of kinematograph pictures illustrating New Guinea native dances Persons desirous of being present can obtain cards of admission on application to the secretary of the Anthropological Institute, 3 Hanover Square, W

IN reply to a question asked in the House of Commons on Monday as to the cause of the recent explosion in the research laboratory at Woolwich, Mr Haldane said —"It is doubtful whether cordite can be detonated, but if it is possible the circumstances must be exceptional Dynamite, if lighted, cannot be detonated unless it is confined. There was no iodide of nitrogen in the research laboratory in the chemical research magazine It can be detonated under water, and cannot be kept in a dry state An inquiry is being held as to the cause of the explosion at Woolwich"

IN January the American Museum of Natural History sent over a party, under Prof H F Osborn, to the Fayûm desert of northern Egypt to explore and collect fossil vertebrates in the Upper Eocene formations made famous by the discoveries of Beadnell and Andrews. Captain H G Lyons, director-general of the Egyptian Survey Department, rendered material assistance in outfitting the expedition, and detailed Mr. H. I. Ferrar, of the survey, for a three weeks' tour of the formations with Prof Osborn As a result of this tour, it was decided to confine the search principally to the Upper Eocene. The party reached the Fayûm on February 5, and at once began the work of prospecting and excavating, which will be continued for two or three months under the direction of Messrs Granger and Olsen, of the American Museum The chief objects of the party are first to secure a representative collection of the extinct animals already known, second, to extend our knowledge of the small fauna of the period The first step in the latter direction has been the discovery of Rodentia apparently of the myomorph group

MR W BURDETT-COUTTS has decided to arrange for the publication in due course of a life of the late Baroness Burdett-Coutts He informs us that he is anxious that those persons who possess letters of interest from the Baroness, addressed to them or their forbears, should send correspondence (after May 1 next) to him at 1 Stratton Street, London, W, or communicate with him on the subject All documents will be treated with great care, and returned as soon as practicable, intact to their owners after the necessary extracts have been made from them At a general monthly meeting of the members of the Royal Institution on Monday, March 4, a letter from Mr Burdett-Coutts was read expressing appreciation of the terms of a resolution, with reference to the death of the Baroness Burdett-Coutts, sent to him by the Royal Institution In the course of his letter, Mr Burdett-Coutts says —The Baroness's social relationships to science, her friendships with many, her acquaintance with nearly all, of its eminent professors for the past seventy years, are well known, her efforts to encourage and aid those who were struggling in the same path, not so well as was her custom If a scholarship was to be established at Oxford, not classics or history, or even theology, but science claimed her aid Such things were not done at haphazard She would spare no trouble to search out both the need and the means With a touch of characteristic humour she inquired of Sir Wm Hooker whether Kew Gardens, so far up the Thames, was not poor in seaweeds She had already found out the fact, and had secured the Griffiths collection, so rare and extensive that, without impairing the central completeness, it provided duplicates for six other botanical establishments She probably had not read Schimper's monograph on the genus Sphagnum, and did not know the details of the muscological collection of Bruch; but she found out that Kew also wanted mosses, and that Schimper's great herbarium could be acquired. Thus, not so much by wealth as by thoughtful insight, special departments of British science were enriched at her hands.

AT the annual general meeting of the Geological Society on February 22, Sir Archibald Geikie, the president, described the arrangements contemplated for the celebration of the society's centenary next September Invitations to attend the meetings will be sent to all the foreign members and foreign correspondents of the society, and geological societies, geological surveys, and learned institutions which

have a geological side, will be asked to send delegates Personal invitations will also be addressed to geologists of note in the old and the new world, who are not already enrolled in the foreign lists of the society The official programme will probably extend over three days in London. The arrangements for each of these three days are under consideration, but Sir Archibald Geikie proposes to give his presidential address as the *pièce de résistance* of one of the forenoon or afternoon meetings In that address he will offer a sketch of the state of geological science outside Britain at the time when the Geological Society of London was founded and indicate the external influences that affected its start. By this choice of a subject he hopes to interest the foreign guests, while at the same time inviting the fellows of the society into a domain of the history of science which is perhaps less familiar than it deserves to be The chronicle of the society itself during the first hundred years of its existence has been carefully and fully compiled from all available sources by Mr Horace B Woodward for publication in volume form Excursions to places of geological note in this country will probably be arranged, some to precede and others to follow the meeting in London The various museums and places of interest in the metropolis will, of course, be shown to the expected visitors, and there will doubtless be no lack of public and private hospitality It is anticipated that the Universities of Oxford and Cambridge will both receive the foreign guests

To *Naturen* for January Prof A W Brogger contributes an illustrated account of the oldest stone implements of Norway These are all Palæolithic, and include "celts," together with two distinct types of "axe-heads"

A PAPER by Mr E D Congdon on the hydroid polyps of Bermuda is published in the January number of the *Proceedings of the American Academy of Arts and Sciences*, and two on plankton crustaceans from the San Diego region, by Mr C Juday, are issued in vol iii (parts ix and x) of the zoological series of the University of California Publications

IN an earlier number of NATURE reference was made to an exhibition in the hall of the Natural History Museum of specimens sent by the Marine Biological Association at Plymouth This exhibit has been augmented by a jar of specimens illustrating the transition from the marine leptocephalus larva into the fresh-water elver, or young eel, and by a second vessel containing specimens of the various animals which go to form the ordinary diet of the cod Thirteen species are included in the latter, among which four are (for the most part immature) fishes

THE January number of the *Victorian Naturalist* contains an account of a traverse of the Owen Stanley Range, British New Guinea by Mr C C Simpson Some interesting observations on the habits of birds-of-paradise, of which several species were seen, are recorded The "six-plumed" and "magnificent" species have dancing grounds, carefully cleared on which they disport themselves, while the "raggiana" has a special tree to which the males resort for their nuptial display but the other species use for this purpose any tree that may be convenient. In the author's opinion, many of the rarer species lay only a single egg

THE Paris illustrated magazine *Madame et Monsieur* for February 17 contains an appreciative account of Prince Roland Bonaparte and his scientific researches The Prince is, indeed, before all things a *savant*, and devotes the whole of his available time to scientific investigation Although botany claims the first share of his attention, he likewise devotes much time and money to anthropology having brought together a unique collection of anthropological photographs, while geology is by no means neglected Prince Roland is likewise a great traveller, having visited a large part of the North American continent The herbarium in his palace in the Avenue d'Iéna *is stated to contain not less than 700,000 species of plants* The Prince has just been elected a member of the French Academy of Sciences

WE have been favoured with a copy of the first part of a new work, "The Kennel Encyclopædia," edited by Mr J. Sidney Turner, and published by the Encyclopædic Press, Sheffield The work, it is estimated, will run to about sixteen parts, to be issued at intervals of from four to six weeks Judging from the illustrations to the article on Airedale terriers the work promises to be of an exceptionally attractive nature Mr R I Pocock contributes an excellent article on the ancestors and relatives of the dog, while Prof Hobday illustrates canine anatomy by means of sketches Mr Croxton Smith, who writes on the antiquity of the dog appears however, to be unacquainted with all the literature of the subject notably a recent article in *Globus*, by Prof Kraemer, on the St Bernard and the Tibet mastiff

MAJOR POWELL COTTON, who recently arrived in this country, during his journey home communicated to Reuter's Agency at Rome some of the results of his twenty-seven months' sojourn in the heart of Africa According to this account, the explorer secured a specimen of the Central African race of the white rhinoceros near Lado Like other British explorers of the Ituri Forest he failed to see a living okapi, although he approached within twenty yards of one in dense jungle The skeleton and skin of a male and the body-skin of a calf were however, secured, and have now been transferred to the British Museum Important information derived from the Ituri pigmies, with regard to the habits of the okapi is promised in due course Several mammals collected have been described as new by Mr Lydekker They are the black honey-badger and local races or phases of the African tiger-cat water chevrotain, Stuhlmann's elephant-shrew, and a guereza monkey from the Ituri Forest together with a large tawny buffalo from the open Semliki country near the Albert Edward Nyanza Major Cotton has demonstrated that the range of the dwarf red buffalo, the water-chevrotain, and the potamogale extends right across the forest region It may be added that Mr Boyd Alexander has presented to the British Museum the skull and skin of an okapi obtained by his expedition in the southern Bahr-el-Ghazal country

PUBLISHED as parts of the current volume of the Kew Bulletin, appendix ii furnishes a catalogue, with alternate pages left blank, of additions to the library during the year 1906, and appendix iii contains a list of new garden plants for the same year Again a large number of the new plants have been obtained from China being introduced by Messrs J Veitch and Sons, derived from the collections made for them by Mr E H Wilson Four species of Primula are added to a previously long list, among them being the vivid blue-flowered *Primula deflexa* Of new species from Brazil a dozen are recorded, all except *Asplenium laceratum* being orchids

A DISCUSSION mainly theoretical of the much debated question of the water supply in plants by Dr A Ursprung, appears in the *Biologisches Centralblatt* (vol xxvii, Nos

1, 2, and 3) The author is a strong advocate of the important part taken by living parenchymatous cells in the ascent of sap, favouring the view that they act chiefly as intermediate pumping stations. It is noticeable that the explanation offered by Askenasy receives brief consideration, and no mention is made of the papers and investigations contributed to the subject by Dixon and Joly or other British workers.

UNDOUBTEDLY the greatest novelty at the rubber exhibition held in Ceylon last August was the sample of pressed or blocked rubber sent from a plantation in the Malay States. As blocked rubber possesses several advantages over "biscuit" rubber, an early opportunity was taken by Dr. J. C. Willis and Mr. M. K. Bamber to prepare an experimental block with creosote to ascertain whether it was suitable for shipment to Europe. The details of the experiment are given in vol. iv., No. 1, of the Circulars and Agricultural Journal of the Royal Botanic Gardens, Ceylon, from which it will be seen that although the block contained a considerable amount of moisture, the price of the sample compared favourably with the best biscuit.

IT is improbable that students of natural history are sufficiently familiar with Crabbe's poetical works to express an opinion on his descriptions of birds and plants. An article on Crabbe as a poet is contributed by the Rev. J. Vaughan to the February number of the *Monthly Review*, claiming that his descriptions of scenery are characterised by their distinctness and accuracy. The botanical references in his writings are practically confined to the district of Aldeburgh in Suffolk, as in the allusion to the salt-marshes where "Samphire-banks and salt-wort bound the flood," &c. But his interest in botany extended much beyond word painting; he was a keen collector, and knew the haunts of such rare plants as *Trifolium suffocatum*, *Pisum maritimum*, and *Urtica pilulifera*; also several note-books still extant indicate that he ardently followed the progress of knowledge with regard to grasses, sedges, and cryptogams.

THE current issue of the Quarterly Journal of the Geological Society (vol. lxiii., part 1) contains a valuable paper by Mr. W. R. Baldwin-Wiseman on the influence of pressure and porosity on the motion of subsurface water. It contains an able summary of the more important investigations of the behaviour of underground water, and shows that by the careful study of the hydrological map of a district which has been surveyed with some exactitude, it is possible to gain a considerable knowledge of the details of the geological structure of the district which might not otherwise be available, and to obtain at the same time valuable data for the scientific solution of the water-supply problems of that district.

THE recent remarkable development of the American iron industry is discussed in some detail by Mr. E. C. Eckel in the *Engineering Magazine* (vol. xxxii., No. 5). Dealing with the important subject of ore reserves, he shows that, on the assumption that the demand for iron ore during the present century may range from 50 to 100 million tons annually, the Lake Superior district would last for from twenty-five to fifty years more if it supplied the entire United States. But, counting on the known reserves elsewhere in the United States, the ore will last for a much longer period, though, of course, it must necessarily show a gradual but steady increase in value. Electric smelting will, he considers, have little influence on the general development of the iron and steel industries until fuel supplies become more scanty than they are at present. Considerably more practical results to the industry can be expected from the nodulising process of treating ore dust. This process accomplishes both the consolidation and desulphurising of the material, and its chief advantage, as compared with the older briquetting and roasting processes, arises from the fact that the rotary kiln employed is distinctly an effective labour-saving device.

THE remarkable paper which Mr. Dugald Clerk read before the Institution of Civil Engineers on February 26 brings us appreciably nearer a complete understanding of the thermodynamics of the internal-combustion engine. He examined the results of the tests made by the institution committee on the standards of efficiency of internal combustion engines, and gives the results of further experiments on the large engine used in the test, with the view of finding the true heat distribution of the engine. Tables are given showing the ideal efficiencies for different compressions using the specific heat values given, and shows that roughly the air standard is 20 per cent. too high, and that if γ, the ratio of specific heat at constant pressure to specific heat at constant volume, be taken as 1·285 for the explosion line and 1·37 for the compression line, the change of specific heat between 1700° C. and 1000° C. commonly used in practice is too small to produce much error. More investigation is, however, required before even the apparent specific heat values can be accurately known for the various mixtures used in internal-combustion motors. For a given expansion the best engines have approached very closely to the theoretical realisation of their cycle. The complete suppression of all heat losses due to conduction, &c., on the explosion expansion strokes could only increase the indicated power by about 13 per cent. It is satisfactory to find that the gas engine is so nearly perfect.

IN his recent notice of Dr. E. W. Scripture's work on experimental phonetics (February 21, p. 392), Prof. McKendrick pointed out that though mention is made in the work that Prof. Weber, with Prof. Schneebeli, applied the Fourierian analysis to a vowel curve, no date is given when this was done. Dr. C. E. Guillaume, of the Bureau international des Poids et Mesures, Sèvres, who was formerly Prof. Schneebeli's assistant, writes to say that the results of researches on the harmonic analysis of vowel sounds during the summer of 1878 were communicated to the Société des Sciences naturelles de Neuchâtel on November 21 of that year. The paper by Fleeming Jenkin and J. H. Ewing referred to by Prof. McKendrick was communicated to the Royal Society of Edinburgh on June 3 and July 1, 1878, and was published in part iii. of vol. xxviii. of the Transactions, which is dated 1879.

WE have received from Messrs. Shelley W. Denton and Co., 99 Regent Street, W., samples of their patent butterfly tablets, containing handsome tropical butterflies and moths, mounted on a special plaster background, and covered with glass in such a manner as to exhibit the wings, antennæ, &c., to perfection, while preserving the specimens from almost any injury short of the actual breakage of the glass cover or of the tablet itself. We believe the process is American, and have been familiar with Messrs. Denton's method for some years, and we are quite ready to concede that it possesses *most* of the merits claimed for it by the firm in the circular which they have sent us. But when they say that the specimens "preserve their rich colours intact," and "they make magnificent wall, table, or mantel ornaments," we can

only point out that light, especially direct sunlight, is always very destructive to the colours of butterflies (though some colours fade more quickly than others), and though they will preserve their colours fairly well for centuries *if kept from the light*, we should strongly recommend any person who values specimens of butterflies to keep them *carefully covered*, except when actually undergoing inspection

WE have before us copies of the reports of the U S National Museum, Washington, for the years ending June 30, 1905, and June 30, 1906 These reports are for the future to be restricted to accounts of the administrative operations of the museum The interesting and well-illustrated papers based on the collections of the museum which in past years have appeared in the appendix to the reports, are for the future to be published in other series The report for the year ending June 30, 1906 shows that the total number of accessions received by the museum during that year was 1516, comprising 257,605 specimens, of which 8232 were assigned to the department of anthropology, 227,633 to the department of biology, and 21,740 to the department of geology In ethnology, large accessions were received from Arizona and New Mexico, the Philippine Islands, and Malaysia The collections in physical anthropology were mainly enriched by material from Malaysia and from ancient Indian ruins and mounds in the western parts of the United States The most important addition to the biological department was the collection of 75,000 American Lepidoptera given by Mr William Schaus, and, besides these 33,000 insect specimens were received through the U S Department of Agriculture In view of annual additions such as these, it is not surprising to learn that "year by year the exhibition cases have been brought closer and closer together, and great spaces have been shut off from the public view to permit of the shelter of thousands of new accessions" Fortunately, the new building for the museum is making satisfactory progress and its completion will make it possible to reveal to visitors the wealth of scientific material which has been amassed in recent years

THE untrustworthiness of the underground conduit system for tramways when confronted with a heavy snowfall is once more brought to our notice in the reply of the manager of the Grand Berlin Tramways Company to the criticisms passed upon the recent breakdown of the few underground conduit lines in Berlin Assertions were made that with the same system other towns on the Continent were free from interruption to their tramways during the recent fall of snow, but the manager in his reply clearly shows that, with the exception of Vienna, all the leading towns on the Continent in which the underground conduit system is employed were in a similar plight, and in Budapest the tramways were completely stopped for several days The report of the Brussels Tramway Company also states that their troubles during the snowy period were due to the underground conductors, and that the working of the lines could not be carried out with a repetition of similar events, in spite of the fact that a large reserve plant was available Vienna is almost an ideal city for conduit work, and has nothing like the traffic of Berlin, and is not, therefore, a fair comparison of everyday working conditions such as we have in London We have before pointed out in NATURE the difficulties attendant on the working of the underground conduit system directly any unusual weather sets in, and the above reports fully bear out the contention that the underground conduit system is not so perfect as some of its disciples would have us believe

UNDER the title "Erinnerungen an Johannes Wislicenus," Dr W Sonne has published (Leipzig W Engelmann, pp 36, price 1 20 marks) a number of personal recollections of Wislicenus during the years 1876–1881 when, at the height of his activity, he was filling the chair of professor of chemistry at Würzburg It was during this period that his work on ethyl acetoacetate was published, partly in collaboration with Conrad and others In 1880 he was associated with Hantzsch, who succeeded him both at Wurzburg and Leipzig The "Erinnerungen" are of value as throwing light on the inspiring personality of Wislicenus, and may be regarded as supplementing the more complete accounts recently given of Wislicenus's work by Prof Beckmann and Prof W H Perkin, jun

MUCH confusion arises at the present time from the lack of understanding, either here or abroad, as to the exact sense in which the various names applied to proteins and their derivatives shall be used Difficulty is created by the use of a term in different senses, as well as ambiguity of meaning in some cases The Chemical Society has for some time had this matter of nomenclature under consideration and has just issued a series of recommendations in its Proceedings (vol xxiii, No 321) The first two recommendations are —(1) The word proteid —which is used in different senses in this country and in Germany—should be abolished (2) The word protein is recommended as the general name of the whole group of substances under consideration It is at present so used both in America and Germany It admits readily of the use of such derived words as protease and proteose If used at all, the term albuminoid should be regarded as a synonym of protein

MESSRS CROSBY LOCKWOOD AND SON have published a second edition of Mr George Clapperton's "Practical Paper-making" The work has been carefully revised and enlarged by twenty pages so as to bring the information up to date

MESSRS MACMILLAN AND CO, LTD, have issued separately certain parts of "An Introduction to Practical Geography," by Mr A J Simmons and Mr Hugh Richardson which was reviewed in our issue for May 10, 1906 (vol lxxiv, p 27) Section i maps, section ii the globe and section iii, climate, may be obtained in small volumes bound in limp cloth, and the price of each is 1s

THE Bulletins of Miscellaneous Information issued during 1906 from the Royal Botanic Gardens, Kew, have been bound together in a single volume, the price of which is 4s The work can be obtained in London from Messrs Wyman and Sons, Ltd, or through any bookseller Reference has been made to separate bulletins from time to time in these columns, and botanical readers of NATURE are familiar with the general character of the publication

OUR ASTRONOMICAL COLUMN

PERTURBATIONS OF HALLEY'S COMET —From an investigation of the Jupiter perturbations of Halley's comet Messrs Cowell and Crommelin find that the perihelion passage of that comet will probably occur about a fortnight earlier than the date given by Pontécoulant that is, in the first half of May, 1910 What is more important they also find that Pontécoulant's perturbations were about ten times too great, and consequently the perihelion distance will be appreciably the same (0 59) as at the last return, instead of being shifted some nine million miles nearer to the earth as found by the French investigator (Monthly Notices, vol lxvii, No 3 January)

STARS HAVING PECULIAR SPECTRA.—Circular No. 124 of the Harvard College Observatory contains the particulars of a number of variable stars and other objects which the Henry Draper memorial photographs, examined by Mrs Fleming show to have peculiar spectra.

The chief peculiarities are bright or multiple hydrogen lines, as, for example, in the spectrum of B.D. +47° 939, a 4.5 magnitude star in Perseus, in which Hβ is bright and the lines Hγ and Hδ appear to be double, probably because fine bright lines are superposed on them. A star in Scorpio, of magnitude 7.1, is found to have a spectrum similar to that of ζ Puppis. Several of the variable stars mentioned show a range of about five magnitudes.

SIMULTANEOUS DISPARITION OF JUPITER'S FOUR SATELLITES.—From a study of the phenomena of Jupiter's satellites, Signor Enzo Mora finds that on October 3, 1907, all four of the larger moons will be invisible, for several minutes, at the same time, and, as this is a rare occurrence, he directs attention to the matter in No. 4148 of the *Astronomische Nachrichten*. From 7h. 48m. to 7h. 54m. (Greenwich Civil Time) No. 1 will be eclipsed and occulted, No. 2 will be in transit, No. 3 will be eclipsed, and No. 4 occulted. The satellites will again be invisible at 9 p.m. on the same evening. The last time this phenomenon occurred was October 21, 1895, and, after October next, it will not occur again until October 22, 1913.

PHOTOGRAPHS OF FAINT STARS.—In Circular No. 123 of the Harvard College Observatory Prof. E. C. Pickering outlines a plan by which the information to be gathered from photographs of stellar regions, taken by numerous observers in various countries, may become readily available to anyone in search of such information. For stars of the thirteenth magnitude and brighter, the Harvard collection of photographs largely supplies the necessary data. For example, for each of the stars of magnitude 5.0 and brighter, some 2000 in number, the collection contains about one thousand photographic images taken during the last twenty years; similarly, for the thirteenth magnitude stars, about five million in number, there are about 200 images of each.

Prof. Pickering now suggests that anyone having in their possession photographs which might furnish useful information, such as the earlier appearance of Novæ, variable stars, &c., should publish particulars of the same, or should forward to him the necessary information in order that it may be included in a publication which the Harvard authorities are preparing, and so become available generally.

MODEL TO ILLUSTRATE EFFECTS OF THE EARTH'S ROTATION.—In No. 7 (February, 1907) of the *Comptes rendus* M. G. Blum describes a simple apparatus for reproducing the phenomena observed in the Foucault-pendulum experiment for showing the earth's rotation. Briefly, the apparatus consists of a sphere representing the earth and a small pendulum which may be made to oscillate on its surface in any latitude. The sphere rotates on an axis, and is slotted along a meridian so that the gallows carrying the pendulum may be clamped on to it at different points representing different latitudes. The oscillation of the pendulum—which consists of a thin wooden rod with a small wooden bob—is produced by a coiled spring, and always takes place in a plane normal to the sphere. With this apparatus the rotation of the plane of oscillation with regard to that of the sphere may be shown to be equal in period and opposite in sense at the poles, and to have a slower period as it approaches the equator, the change being so marked that it can be readily seen and its nature recognised.

PROMINENCE OBSERVATIONS (1906).—No. 1, vol. xxxvi. (1907), of the *Memorie della Società degli Spettroscopisti Italiani* contains a posthumous note of Prof. Mascari giving the results of the solar-prominence observations made at Catania during the first half of 1906. Three hundred and forty prominences were observed on eighty-seven days, giving a daily frequency of 3.91. In the northern hemisphere the daily frequency was 2.32 and the mean heliographic latitude 31°.6, the corresponding figures for the southern hemisphere being 1.59 and 29°.2 respectively.

METEOROLOGICAL OBSERVATIONS.

SUNSHINE and Snowfall in 1906.—In *Symons's Meteorological Magazine* for January, Mr. R. H. Curtis gives an interesting summary, with map, of the bright sunshine over the British Isles, registered by the Campbell-Stokes (burning) recorder. The year was one of the sunniest on record; the most favoured region was the English Channel, all stations from Torquay to Lowestoft recording approximately 2000 hours of sunshine. At inland stations the amount became less, yet, broadly speaking, all the region south of a line drawn from the Humber to the Bristol Channel received 200 hours more than the yearly average. In north-west Scotland the amount was below 1200 hours, which was not far from the average of that district. The most brilliant months (relatively to their possible amounts) were February, April, June, July, and September; the most sunless months were May and November, in both of which the amounts recorded were generally below the average.

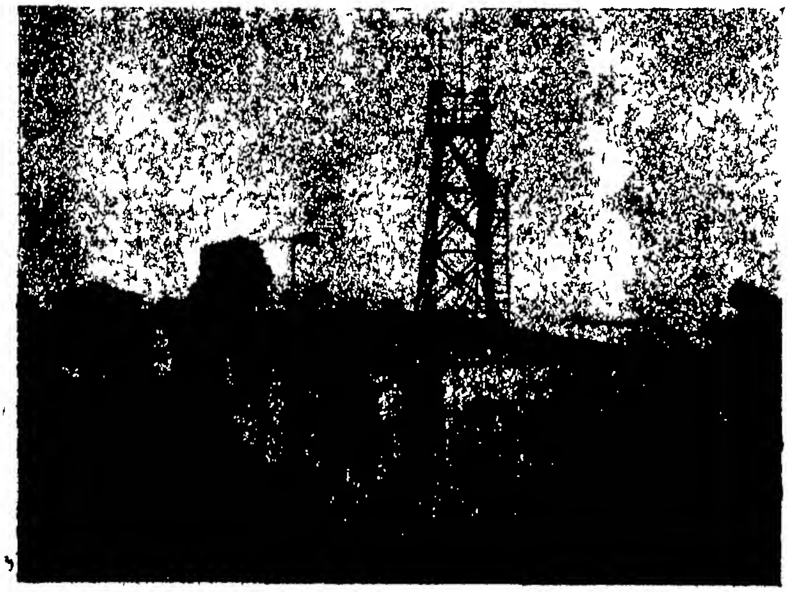
The snowfall is preliminarily dealt with by the editor, with especial reference to the storms between December 25–30, which occurred over nearly the whole of the British Isles. Considerably more than half the kingdom received above 5 inches, and some districts, especially north-east England and the southern uplands of Scotland, from 1 foot to 2 feet in depth. In the south of Scotland trains were blocked; Aberdeen was isolated for several days, and a most serious railway collision occurred near Arbroath. Although the greatest amounts recorded were in Scotland, Dr. Mill points out that the severity of the storm in Ireland, where more than a foot was recorded in the north and west, was noteworthy, owing to its usual immunity from heavy snowfalls, an amount of 5 inches over wide districts being very unusual there.

Rainfall of Scotland in May, 1906.—In discussing this subject in the Journal of the Scottish Meteorological Society, Mr. A. Watt shows that the rainfall of Scotland in that month was of a very exceptional character; in the eastern districts, generally, the fall was much the heaviest in May during the last fifty years. The rainfall on the east coast was heavier than that on the west; only a few scattered stations towards the north-west did not receive as much as 3 inches, about nine-tenths of the mainland received at least 4 inches, while a large area in the south and south-east and other isolated parts received 6 inches and upwards, or about thrice their normal amount. A note by Mr. R. C. Mossman on the conditions experienced by himself in the Greenland Sea during the month in question shows that the weather there was unusually inclement; the characteristic features were high barometric pressure, accompanied by strong north-west and north winds and gales, very low mean temperature, and densely overcast skies. Mr. Mossman states that there can be little doubt that the Arctic anticyclone was the dominating factor in the production of the abnormal rainfall in Scotland, and also of the unusually high temperatures observed in Russia at the same time, referred to in Mr. Watt's paper.

The Atmosphere in the Tropics.—In the Proceedings of the American Academy of Arts and Sciences for December, 1906, Mr. A. L. Rotch gives the results of the Franco-American expeditions undertaken at the expense of M. Teisserenc de Bort and himself to prove, by means of kites and unmanned balloons, the direction of the upper return currents above the trade-wind region of the North Atlantic. For this purpose M. Teisserenc de Bort purchased and equipped the steam yacht *Otaria*, of 350 tons, and expeditions were made in the summer of 1905 and in the winter (February) of 1906. With regard to the results of the first expedition, Mr. Rotch states:—(1) north of Madeira and near the Azores the upper winds are chiefly from west and north-west; (2) winds blowing towards the equator are from north-east to east in the lower region, and generally from north-west to north-east above 1000 metres; (3) the return currents from the equator, or anti-trades, are formed by winds having a southerly component, being generally south-west in the latitude of the Canaries, and south-east near the Cape Verdes. As most of the observations of direction of the upper currents found by Prof. Hergesell during the cruises of the *Princesse Alice*

in 1904–5 differ radically in showing no southerly component, the *Otaria* was sent again to the south and west of the region which had been explored in the preceding summer. Mr. Rotch states that the upper anti-trade is shown both by the balloons and the drift of the clouds between 3000 metres and 4000 metres, and that the classic observations of the return trade on the Peak of Teneriffe indicate a general phenomenon, and agree with those obtained over the open ocean by the recent expedition Prof. Hergesell's remarks upon this subject were referred to in NATURE of December 27, 1906 (p. 211).

Meteorological Observations on the Summit of the Tsukubasan, Japan.—The establishment of this first-order observatory, and the determination of the force of gravity and exact geographical position, are due to the interest taken in physical science by H.I.H. Prince Yamashina. The observatory is situated on the most westerly peak of the mountain, in lat. 36° 13′ 21″ N., long. 140° 5′ 47″ E., about forty miles north-east of Tokio, at an altitude of 2852 feet. It commands the view of the surrounding district for many miles to the north and west, while to the south and east it has an open view of the wide expanse of the Pacific Ocean. Its position is therefore extremely favourable for studying the conditions of the atmosphere at that height. As connecting links, intermediate stations have been established near the little village of Tsukuba, at an altitude of 787 feet, and at the base of the south-west of the mountain, 98 feet above sea level. The illustration represents the peak observatory, which is constructed of wood and zinc, the main objects being durability and usefulness, without any attempt at ornamentation. On the roof are seen the rain-gauges, lightning conductor, and wind-vane, close to the main building, on the north-east, stands a steel tower carrying another lightning conductor, anemometers for recording both horizontal and vertical movements of the wind, and a sunshine recorder, while the thermometer screen is seen to the south-west of the building. It goes without saying that the instruments are of the best make, although the sunshine recorder is of the photographic (Jordan) type, not the burning (Campbell-Stokes) pattern. The latter instrument alone is now used at the stations of the British Meteorological Office, as giving strictly comparable results. The observing staff consists of a director and five assistants, at the time of the publication of the first report, for the year 1902, the observatory and subsidiary stations were under the supervision of Mr. Okada, adjunct of the Central Meteorological Office at Tokio, the control of the observers and other details being undertaken by Mr. J. Sato, chief observer at the peak station. The computation of the mean and extreme values for 1902 from hourly readings for all three stations, and tables showing the ranges and wind frequency and velocity, are carefully prepared, but no general textual summary of results is given. At the base station only the rainfall observations are complete for the year, the total fall was 63.72 inches, and at the peak station 62.82 inches. The absolute ranges of the barometer at the summit and intermediate stations were practically the same, being 1.87 inches and 1.78 inches respectively. The mean annual temperatures at these two stations were 48°.2 F. and 55°.2 F., and the absolute ranges 59°.2 and 37°.4 respectively. The resulting wind direction at the summit, computed from the records of a Robinson's anemometer, was N. 82° E., resultant velocity 0.39 metre per second (0.87 mile per hour), the mean hourly velocity, irrespective of direction, was approximately 17.2 miles.



The Meteorological Observatory on the Tsukubasan.

Meteorology of India.—The Meteorological Department of India has issued a memorandum on the weather conditions during October and November, 1906, with a forecast of the rainfall in northern India and of the snowfall on the neighbouring mountain areas during the cold weather of 1906–7. Dr. Walker states that on the average of the whole country there was a defect of 22 per cent. in the rainfall of October and of 20 per cent. in November. The temperature conditions were determined by the distribution of rainfall, in the latter month the weather was unusually warm over practically the whole of the country, and especially in the North-Western Provinces. From information available, the snowfall also appears to have been less than usual. Among other factors affecting the cold-weather season, the director points out (1) that the active state of the sun during the past year is an element that should be taken into account, the number of sun-spots observed in 1906 is in moderate excess, which fact, if taken alone, suggests that a severe winter is rather more likely than a mild one. (2) That the mean of the departures of November rainfall at Zanzibar and Seychelles is −1.8 inches, which taken by itself suggests that the approaching cold-weather precipitation may be somewhat lighter than usual. All things considered, the final conclusion is that there is no reason for expecting any large departure from normal conditions.

Meteorological Observations in Cape Colony.—The report of the Meteorological Commission for the year 1905 shows that a large amount of useful work is being carried out in rather adverse circumstances. The sum received from the Parliamentary Grant for the year did not exceed 862*l.*, the supply of instruments and reduction of anemometrical and other observations have consequently been curtailed, while no general inspection of stations has been made since 1901. The results are published for a large number of ordinary meteorological and rainfall stations, some of which belong to adjacent territories outside the boundaries of Cape Colony; the report also contains a useful monthly chronicle of the weather by Mr. C. M. Stewart (secretary), and special tables of the maximum daily rainfall at various stations. The mean rainfall for the year, deduced from all the stations, was 23.77 inches, occurring on sixty-five days; the amount was only about 0.1 per cent. below the average for 1885–1894, and was an increase of 3.61 inches above the mean for 1904. The four largest records in one day were 11.33 inches at Evelyn Valley, on October 10, 10.70 inches at Durban, on June 1, 10.37 inches at Vogel Vlei, on April 9, and 10.18 inches at Forestbourne, on October 10. Thunder storms were unusually frequent in December and practically absent in July. The highest temperature recorded was 119°.5 at Main, on November 19, and the lowest

17°·0 at Moyeni, Basutoland, on August 23. The mean yearly value of the absolute maxima was 86°·9, and of the corresponding minima 41°·6. The mean temperature for the year was 0°·9 below the average. The stormiest month was October, and the calmest was April.

We have also received the official meteorological year-books for South Australia (1904) and Mysore (1905). Both of these works contain valuable means for previous years.

Forty Years of Southern New Mexico Climate.—Bulletin No. 59 of the New Mexico College of Agriculture contains the meteorological data recorded at the experimental station from 1892 to 1905 inclusive, together with results of temperature and rainfall observations at other stations in the Mesilla Valley for most of the years between 1851 and 1890 published some years ago by General Greely in a "Report on the Climate of New Mexico." The station is situated in lat. 32° 15′ N., long. 106° 45′ W., and is 3868 feet above sea-level. The data have a general application to those portions of southern New Mexico with an altitude less than 4000 feet. The mean annual temperature for the whole period was 61°·6; mean maximum (fourteen years) 76°·8, mean minimum 41°·4, absolute maximum 106° (which occurred several times), absolute minimum 1° (December, 1895). The mean annual rainfall was 8·8 inches, the smallest yearly amount was 3·5 inches, in 1873, the largest 17·1 inches, in 1905. Most of the rain falls during July, August, and September. The relative humidity is low, the mean annual amount being about 51 per cent. The bulletin was prepared by J. D. Tinsley, vice-director of the station.

Meteorological Observations in Germany.—The results of the observations made under the system of the Deutsche Seewarte, Hamburg, for 1905, at ten stations of the second order and at fifty-six storm-warning stations, have been received. This is the twenty-eighth yearly volume published by the Seewarte, and forms part of the series of German meteorological year-books. We have frequently referred to this excellent series, and the volume in question is similar in all respects to its predecessors; it contains most valuable data relating to the North Sea and Baltic coasts. We note that the sunshine at Hamburg was only 29 per cent. of the possible annual amount, and that there were 103 sunless days; the rainfall was 25·9 inches, the rainy days being 172 in number.

VOX POPULI.

IN these democratic days, any investigation into the trustworthiness and peculiarities of popular judgments is of interest. The material about to be discussed refers to a small matter, but is much to the point.

A weight-judging competition was carried on at the annual show of the West of England Fat Stock and Poultry Exhibition recently held at Plymouth. A fat ox having been selected, competitors bought stamped and numbered cards, for 6*d*. each, on which to inscribe their respective names, addresses, and estimates of what the ox would weigh after it had been slaughtered and "dressed." Those who guessed most successfully received prizes. About 800 tickets were issued, which were kindly lent me for examination after they had fulfilled their immediate purpose. These afforded excellent material. The judgments were unbiassed by passion and uninfluenced by oratory and the like. The sixpenny fee deterred practical joking, and the hope of a prize and the joy of competition prompted each competitor to do his best. The competitors included butchers and farmers, some of whom were highly expert in judging the weight of cattle; others were probably guided by such information as they might pick up, and by their own fancies. The average competitor was probably as well fitted for making a just estimate of the dressed weight of the ox, as an average voter is of judging the merits of most political issues on which he votes, and the variety among the voters to judge justly was probably much the same in either case.

After weeding thirteen cards out of the collection, as being defective or illegible, there remained 787 for discussion. I arrayed them in order of the magnitudes of the estimates, and converted the *cwt.*, *quarters*, and *lbs.* in which they were made, into lbs., under which form they will be treated.

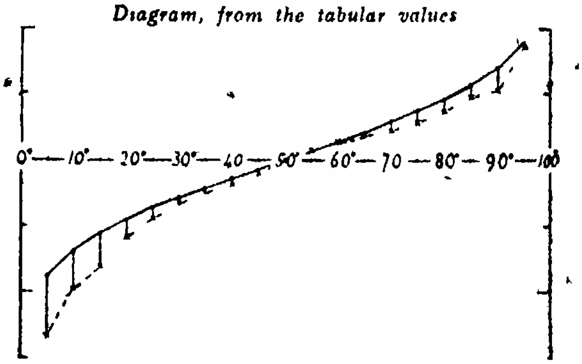
Distribution of the estimates of the dressed weight of a particular living ox, made by 787 different persons.

Degrees of the length of Array 0°–100°	Estimates in lbs.	Centiles: Observed deviates from 1207 lbs.	Centiles: Normal p.e. = 37	Excess of Observed over Normal
5	1074	−133	−90	+43
10	1109	−98	−70	+28
15	1126	−81	−57	+24
20	1148	−59	−46	+13
q_1 25	1162	−45	−37	+8
30	1174	−33	−29	+4
35	1181	−26	−21	+5
40	1188	−19	−14	+5
45	1197	−10	−7	+3
m 50	1207	0	0	0
55	1214	+7	+7	0
60	1219	+12	+14	−2
65	1225	+18	+21	−3
70	1230	+23	+29	−6
q_3 75	1236	+29	+37	−8
80	1243	+36	+46	−10
85	1254	+47	+57	−10
90	1267	+52	+70	−18
95	1293	+86	+90	−4

q_1, q_3, the first and third quartiles, stand at 25° and 75° respectively.
m, the median or middlemost value, stands at 50°.
The dressed weight proved to be 1198 lbs.

According to the democratic principle of "one vote one value," the middlemost estimate expresses the *vox populi*, every other estimate being condemned as too low or too high by a majority of the voters (for fuller explanation see "One Vote, One Value," NATURE, February 28, p. 414). Now the middlemost estimate is 1207 lb., and the weight of the dressed ox proved to be 1198 lb.; so the *vox populi* was in this case 9 lb., or 0·8 per cent. of the whole weight too high. The distribution of the estimates about their middlemost value was of the usual type, so far that they clustered closely in its neighbourhood and became rapidly more sparse as the distance from it increased.

Diagram, from the tabular values.



The continuous line is the normal curve with p.e. = 37.
The broken line is drawn from the observations.
The lines connecting them show the differences between the observed and the normal.

But they were not scattered symmetrically. One quarter of them deviated more than 45 lb. above the middlemost (3·7 per cent.), and another quarter deviated more than 29 lb. below it (2·4 per cent.), therefore the range of the two middle quarters, that is, of the middlemost half, lay within those limits. It would be an equal chance that the estimate written on any card picked at random out of the collection lay within or without those limits. In other words, the "probable error" of a single observation may be reckoned as ½(45+29), or 37 lb. (3·1 per cent.). Taking this for the p.e. of the normal curve that is best adapted for comparison with the observed values, the results are obtained which appear in above table, and graphically in the diagram.

The abnormality of the distribution of the estimates now becomes manifest, and is of this kind The competitors may be imagined to have erred *normally* in the first instance, and then to have magnified all errors that were negative and to have minified all those that were positive The lower half of the "observed" curve agrees for a large part of its range with a normal curve having the p.e = 45, and the upper half with one having its p e = 29 I have not sufficient knowledge of the mental methods followed by those who judge weights to offer a useful opinion as to the cause of this curious anomaly It is partly a psychological question, in answering which the various psychophysical investigations of Fechner and others would have to be taken into account Also the anomaly may be partly due to the use of a *small* variety of different methods, or formulæ, so that the estimates are not homogeneous in that respect

It appears then, in this particular instance, that the *vox populi* is correct to within 1 per cent of the real value, and that the individual estimates are abnormally distributed in such a way that it is an equal chance whether one of them, selected at random, falls within or without the limits of −3 7 per cent and +2 4 per cent of their middlemost value

This result is, I think, more creditable to the trustworthiness of a democratic judgment than might have been expected

The authorities of the more important cattle shows might do service to statistics if they made a practice of preserving the sets of cards of this description, that they may obtain on future occasions, and loaned them under proper restrictions, as these have been, for statistical discussion The fact of the cards being numbered makes it possible to ascertain whether any given set is complete

FRANCIS GALTON

THE WORK OF THE OPTICAL SOCIETY [1]

THOUGH it is perhaps seldom that the Transactions of the Optical Society contain much record of original research, yet they often furnish matter of considerable value to the practical optician, and will usually be found to contain more than one paper of importance to the student of optics The first paper in the present volume will have interest for many readers It is a short and clear statement, by one well qualified to judge, Mr W A Dixey, of the case for the use of periscopic lenses in spectacles A periscopic lens, as defined by Mr Dixey, is one through which its wearer can look obliquely as well as directly without his vision being impaired by radial astigmatism The result is attained either by deepening the curves of the lens so as to produce an approximation to a sphere the centre of which coincides with the centre of rotation of the eye, or by the use of toric lenses A careful reading of Mr Dixey's paper would probably lead many wearers of spectacles to pay another visit to the optician

The paper by Mr Theodore Brown, on direct stereoscopic projection, is of special interest It describes an ingenious device for obtaining stereoscopic effects in pictures projected on a screen, of which probably more will be heard. The argument is that in binocular vision the stereoscopic effect is due to the fact that the two images of the same object in the two eyes are not formed in similar positions on the retina, and that it should be possible to produce stereoscopic effects even when one eye only is used if by some means two simultaneous pictures can be formed on the retina in appropriate positions Owing to the permanence of retinal impressions, this can be effected by throwing on the screen with rapid alternation the two stereoscopic pictures in somewhat displaced positions The displacement is produced by giving a motion to the projection camera, and the stereoscopic can be combined with the "bioscopic" effect by the use of a kinematograph mechanism It is clear from the paper and the discussion that further perfection of detail is necessary to produce completely satisfactory results but there seems no reason why the difficulties should not be overcome There is, however, some reason for suggesting that perhaps a one-eyed spectator would be the most appreciative

In "A Method of Testing Prisms," Mr S D Chalmers, the head of the optical department at the Northampton Institute, suggests some useful applications of the method of auto-collimation for the determination of the angles of prisms to the highest possible accuracy We would direct attention especially to the procedure suggested for the measurement of one of the angles of a 60° prism ABC Rays entering perpendicular to the face BC are totally reflected at 30° from CA or AB, and reflected normally at AB or CA, emerging again approximately perpendicular to BC From the separation of the incident and emergent rays the error in the angle A can be determined Only one reflection takes place normally at a glass-air surface, and there is, therefore, no difficulty in seeing the image Simultaneous observation of the direct reflection from BC aids in setting the prism A similar method can readily be applied in other instances and the figures in the paper suggest at once the procedure in the cases which occur most frequently The lack of parallelism in plane parallel glass can also be tested in this manner Rigidity is, of course, essential in the apparatus to be employed for the observations, and Mr Chalmers has obviously given some attention to details in the construction of a suitable auto-collimator, drawings or diagrams of this would have added to the value and interest of the paper

Mr I W Phillips, student member, in a paper on the measurement of absorption in tinted glasses, describes some observations on the absorption of light by coloured glasses, such as are used for spectacles, a "flicker" photometer being employed for the measurements The method does not admit of great accuracy but is no doubt useful within certain limits for rough work of the kind suggested It raises, however, some vexed questions as to the photometry of coloured lights and some points of interest in relation to the "flicker" instrument were brought up in the discussion by Dr Garnett and others

A presidential address by Prof Silvanus P Thompson, on the early literature of optics, demands no more than passing mention here, great though its interest must have been to those who had the pleasure of listening to it The volume closes with a contribution by Mr A I Bull entitled "Some Notes on the Nature of Vision" The paper, being essentially of the nature of notes, passes rapidly over many points of interest in connection with the mechanism of vision and the molecular and other phenomena accompanying it Various topics are thus touched on from the accuracy of the photometric results obtained with rotating sectors to the difficulties yet requiring explanation on the Darwinian theory in regard to the process of evolution of vision The notes are suggestive, but would make more interesting reading if less loosely put together

We would venture to suggest, in conclusion, that the editing of the volume leaves something to be desired It may be possible to interpret such phrases as "beep lenses on the Willaston principle," and to escape being deceived by the "dissimulation" of a photochemical body, but the fact that Lewis Carroll was a mathematician does not sufficiently justify such imitation of his playful extravagances in a scientific journal, and the volume is marred by many such misprints

THE COMPRESSIBILITY OF CRYSTALLINE ROCKS [1]

THE latter-day revival of interest in geological physics has led to a keen demand for experimental data the absence of which has hitherto rendered futile most speculation in this domain Our almost complete ignorance of the simplest physical constants of rocks and the rock-forming minerals is easy to account for The kind of investigation required is both difficult and laborious, calling for skill and practice as well as the appliances of a well-equipped physical laboratory and the geologist may lack either the capacity or the opportunity for such re-

[1] Transactions of the Optical Society, London, Session 1904–5 Pp 93 Price 10s

[1] "An Investigation into the Elastic Constants of Rocks more Especially with Reference to Cubic Compressibility" By Prof Frank D Adams and Prof Ernest G Coker Pp 69. (Washington, D C Carnegie Institution, 1906.)

searches On the other hand, the professed physicist, interested in the properties of matter from a more general point of view, prefers to work on materials of a more tractable nature than those with which the geologist is concerned

The memoir before us, the joint work of a geologist and an engineer, deals with the constants of elasticity of a number of crystalline rocks, and gives the results of a series of experiments made in the laboratories of McGill University at Montreal The quantities investigated are among the prime desiderata of geological mechanics, being involved in the calculation of the velocity of propagation of earthquake shocks and in other important questions The only data of this kind previously published seem to be open to serious criticism, and the contribution by Profs Adams and Coker is specially opportune and welcome

The authors describe the method employed and the precautions taken to ensure such accuracy as is possible The rock is cut to the shape of a column 3 inches high and 1 inch in diameter, either square or circular in cross-section The column is subjected to pressure applied perpendicularly upon its ends, and the resulting longitudinal compression and lateral extension are observed In this way are obtained Young's modulus, E (the longitudinal stress divided by the longitudinal compression), and the ratio (m) of longitudinal compression to lateral extension (*i e* the reciprocal of Poisson's ratio) The modulus of cubical compression (D) is then calculated from the relation

$$D=\tfrac{1}{3}\left(\frac{m}{m-2}\right)E,$$

and the modulus of shear (C) from

$$C=\tfrac{1}{2}\left(\frac{m}{m+1}\right)E$$

From the theoretical point of view these equations do not seem to be fairly applicable to the case in hand A crystalline rock is an aggregate of many crystals, each of which is anisotropic, and in the case of such a rock as granite the crystals belong to a number of distinct minerals, differing as regards their elastic constants The argument that an average isotropic effect will result from the random orientation of a large number of anisotropic crystals is not quite convincing Nevertheless, the results found are reasonable and consistent, and go far towards justifying the method adopted

When the relation of strain to stress is plotted on a diagram, it is seen in every case that the progressive loading gives a curve not very different from a straight line, while the corresponding line for unloading is a curve lying very near the other, and returning to the initial point It follows that the rocks examined approximate nearly to perfect elasticity, and obey Hooke's law somewhat closely, and with small hysteresis, for pressures ranging up to 10 000 lb or even 15,000 lb to the square inch Many of them compare favourably in these respects with cast iron We quote some of the results obtained for the seventeen rocks examined The figures are to be multiplied by 10^{11} to give the measure in C G S units —

	D	C
Cast iron	6 897	4 132
Carrara marble	4 090	2 171
Peterhead granite	3 300	2 340
Quincy granite	2 750	1 916
Nepheline syenite, Montreal	4 290	2 505
New Glasgow Anorthosite	5 760	3 275
Sudbury diabase	7 329	3 700

It appears that the granites offer less resistance, both to compression and to shearing, than the basic igneous rocks The authors connect the greater compressibility of the granites with the presence of quartz, but the granites appear to be actually more compressible than that mineral We should suppose rather that the alkali-felspars, which constitute the greater part of an ordinary granite, are notably more compressible than the ferro-magnesian silicates and lime-felspars, and this seems to be confirmed by the intermediate value found for the nepheline-syenite[1] The general character of the rocks which compose the bulk of the earth's crust is doubtless fairly represented by the crystalline igneous rocks selected for investigation, and the average compressibility must lie between the highest and lowest values tabulated above. A simple average of all the igneous rocks examined gives a modulus of compressibility $4\cdot374\times10^{11}$, which is slightly less than that for plate glass. In such an average the acid rocks are probably over-represented, and the value consequently too low.

A. H.

[1] The authors cite Voigt's value for the compressibility of quartz. The more accurate determination by Amagat gives 4 212 in terms of the unit adopted above For the felspars there are no known data.

CYANOGENESIS IN PLANTS AND THE CONSTITUTION OF PHASEOLUNATIN

SINCE 1900 a considerable number of plants yielding prussic acid have been investigated in the Scientific and Technical Department of the Imperial Institute Among these are *Lotus arabicus*, a plant which grows commonly along the valley of the Nile, *Sorghum vulgare*, widely cultivated as a cereal in tropical countries, the Lima bean (*Phaseolus lunatus*), common flax, and cassava (*Manihot utilissima*) The source of prussic acid in each of these cases has been proved to be a glucoside, which in the presence of water is decomposed by an enzyme, also occurring in the plant, yielding prussic acid, glucose, and a third neutral substance Three of these glucosides have been fully studied by Prof Dunstan and Dr Henry Lotusin, $C_{28}H_{31}O_{16}N$, from *Lotus arabicus*, is comparatively complex in structure, and is the lotoflavin ether of maltose cyanohydrin, lotoflavin being a yellow colouring matter isomeric with fisetin and luteolin, and belonging, like these, to the quercetin group of dyes Dhurrin, $C_{14}H_{17}O_7N$, from *Sorghum vulgare*, is a dextrose ether of parahydroxybenzaldehyde cyanohydrin Phaseolunatin, $C_{10}H_{17}O_6N$, which occurs in the Lima bean, flax, and cassava, has been shown to be a dextrose ether of acetone cyanohydrin (Phil Trans, 1901, B, 515, 1902, A, 399, Proc Roy Soc, 1903, lxxii, 285, 1906, lxxviii 145 and 152 British Association Reports, 1906, and *Ann Chim Phys*, 1907, [viii], x, 118)

In a paper communicated to the meeting of the Royal Society held on February 28, the same authors, in conjunction with Dr Auld, gave the results of some further investigations carried out with the object of determining the nature of the dextrose residue present in phaseolunatin

Fischer and others have shown that glucosides are divisible into two classes, derived respectively from the α and β forms of the hexoses, and that the glucosidolytic enzymes which occur in plants also belong to two groups the one, typically represented by maltase, being capable of decomposing α-glucosides, and the other, of which emulsin is the best known, having the power of hydrolysing β-glucosides From the results of the examination of the sugar initially produced when phaseolunatin is hydrolysed by the enzyme, which occurs in association with it in the Lima bean, it is clear that this is α-dextrose, and, therefore, that phaseolunatin is the α-dextrose ether of acetone cyanohydrin It is the first naturally occurring glucoside of this type so far known

This conclusion has rendered necessary a further investigation of the enzymes, which occur with phaseolunatin in the Lima bean, the flax plant, and cassava The mixture of enzymes, prepared in the usual manner from the Lima bean, decomposes amygdalin and salicin, and may therefore be assumed to contain emulsin The latter, prepared from sweet almonds, has, however, no action on phaseolunatin, and this is in harmony with the constitution now assigned to the latter glucoside, since the emulsin of almonds has been shown to hydrolyse only glucosides containing β-sugar residues

It has now been found that the Lima bean contains, in addition to emulsin, a second enzyme, which is of the maltase type, and that the decomposition of phaseolunatin, which takes place when the beans are ground up in water, is due to the action of the maltase-like enzyme The maltase of yeast is also capable of decomposing phaseolunatin, so that the enzyme which occurs in the Lima bean appears to be of the same type as the maltase present in yeast

The mixtures of enzymes occurring in association with phaseolunatin in the flax plant and in cassava have also been investigated and found to behave in the same manner as the mixture of enzymes prepared from the Lima bean.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr R C Punnett has been re-elected for three years to a fellowship at Gonville and Caius College, in recognition of his researches in zoology, and Mr C. M Doughty, the distinguished Arabian traveller, author of "Arabia Deserta" and other works, has been elected an honorary fellow of the same college

The general board of studies will proceed shortly to the appointment of a university lecturer in pathology in connection with the special board for medicine, to hold office until December 31, 1911 The annual stipend is 100*l* Candidates are requested to send their applications, with testimonials, on or before Tuesday, March 12

Prof A C Seward, professor of botany, has been nominated to represent the University at the celebration of the three-hundredth anniversary of the death of Ulisse Aldrovandi, to be held in Bologna in June

The council of the Senate has appointed Prof G Sims Woodhead as the representative of the University of Cambridge on the council of the Lister Institute of Preventive Medicine, in the place of the late Sir Michael Foster

The general board of studies has appointed Dr G S Graham Smith to be university lecturer in hygiene for the five years from January 1, 1907 to December 31, 1911, and the appointment has been confirmed by the special board for medicine

The governing body of Gonville and Caius College proposes in June next to make an election to the Sir Thomas Gresham research studentship in economics The value of the studentship will be 120*l* a year Candidates for the studentship must be more than twenty-one and under twenty-five years of age on the first day of October 1907 The election will not be made on the result of a competitive examination Applications should be made before June 1 to the master (the Rev F S Roberts), who will be glad to supply further information

The general board of studies has received a memorandum from the board of agricultural studies embodying a statement presented to that board by the forestry committee of the board to the effect that the committee has during the past year made efforts to obtain such contributions from public bodies and individuals interested in the subject, and is able to report that the efforts have met with a gratifying response The board is now assured of grants for various terms of years amounting to upwards of 500*l* These there is reason to expect will in most cases be renewed Donations or promises of donations have also been received from other contributors amounting to a considerable sum, and a beginning has been made in the collection of specimens for a forestry museum The general board is of opinion that for the proper organisation of this instruction, in addition to the teaching already provided in connection with the Department of Agriculture the services of two special teachers are required One of these should be a forestry expert, capable of assuming the general direction of the students' work, of advising the committee and other bodies, such as colleges and local education authorities, on technical subjects and of promoting study and research in forestry The board thinks that he should have the status of a reader and should have a stipend of 400*l* The other teacher should have a particular branch or branches assigned to him and should be a university lecturer The board of agricultural studies accordingly desires to submit a series of proposals to the Senate embodying these recommendations

The appointments board has presented to the Senate the report for the year 1906 In the year ending December 31, 1906, 136 appointments were obtained on the introduction of the appointments board, by graduates on the register. These appointments include appointments of a public character at home and abroad, as well as industrial and technical appointments, engineering appointments, administrative appointments on railways, appointments for scientific work of various kinds, and lectureships in university colleges. The board has decided in future to make recommendations for scholastic appointments, and some progress has already been made in this direction

DR J M BEATTIE, senior assistant to the professor of pathology, University of Edinburgh, has been elected by the council of the University of Sheffield to the chair of pathology in succession to Dr Cobbett, who has resigned the chair on his appointment as lecturer on bacteriology at Cambridge.

AN official fellow in natural science will shortly be appointed by the principal and fellows of Jesus College, Oxford. The fellow will be expected to teach one of the larger subjects recognised in the honour school of natural science, to undertake the entire direction of the science tuition of the college, and generally to superintend the college laboratory, now in course of erection, this, when completed, will be adapted for the teaching of chemistry and physics The stipend will be not less than 450*l* per annum, together with the free use of rooms in college, and the usual allowances Further particulars may be obtained by application to the principal, Jesus College, Oxford

THE Copenhagen correspondent of the *Times* reports that at a meeting in that city on February 26 the proposal to establish a second university for Denmark at Aarhuus equal to that existing in Copenhagen, was supported by well known men of science and politicians alike Though the sympathy with the new university idea is very great, the correspondent says a Bill can hardly be laid before the present Parliament, which closes its session within four or five weeks In view of the satisfactory state of the national finances, however, it is said to be probable that ultimately a new university will be erected at Aarhuus

THE Prince of Wales presided at a special meeting of the Royal Commission for the Exhibition of 1851 at Marlborough House on February 28 when a resolution was passed granting a site on their estate at South Kensington for the erection of the proposed Royal Institute of Technology The commissioners have also granted a site on their estate for the Institute of Medical Sciences (University of London) It is understood that the site will be reserved for a period of one year, during which it is hoped that the additional sum of about 30,000*l* required to build and equip the institute may be obtained

A LETTER has been addressed to the President of the Board of Education by the Vice Chancellor of the University of London expressing satisfaction that although it has not been found practicable to accept proposals for the immediate incorporation in the University of the new technological institution at South Kensington, the course of action proposed will tend to facilitate the accomplishment at an early date of the objects the Senate of the University has in view The Senate fully appreciates the disadvantages which would attend any further delay in the establishment of the new college The Vice-Chancellor concludes his letter by expressing the hope that during the time before the appointment of the Royal Commission proposed by the President of the Board of Education, the new governing body and the Senate may find themselves, as a result of friendly discussion, in a position to submit to the Board joint proposals for complete incorporation, and so avoid the need for a commission

THE late Mr C J Oldham a well-known ophthalmic surgeon left large bequests for educational purposes These gifts include —10,000*l* to the principal and three other members of the governing body of Corpus Christi College, Oxford as trustees, to be applied as to one-third in the award of scholarships for proficiency in or furthering the study of classics, and as to the remaining two-thirds to be applied to the advancement of general learning in that college, 5000*l* to the University of Oxford 5000*l* to the University of Cambridge each of these bequests to be applied to the encouragement of the study of Latin and Greek and to the works of Shakespeare and 3000*l* to the Manchester Grammar School The residue of the testator's property, which will apparently amount to between 15,000*l* and 20,000*l*, is left as one-half to Corpus Christi College, Oxford, and one-half to Manchester Grammar School

THE annual meeting of the Institute of Chemistry was held on March 1 Prof P F Frankland F R S, president, was in the chair The report which was adopted,

shows that the institute now has 1016 fellows and 177 associates The president, in his address, said the most important feature of the year's work has been the inauguration of examinations in chemical technology The council believes that the institution of these examinations will materially help fellows and associates to obtain employment in chemical industries Another piece of work accomplished has been the publication of a list of official chemical appointments Commenting on the value of the qualifications of the associateship and fellowship of the institute, the president showed how the examinations of the institute differ from those of the universities The latter he said, are contrived to test the amount of knowledge which a candidate has succeeded in bringing to a focus at a particular moment, while the main object of the institute's examinations is to test what the candidate can actually perform when he is placed as nearly as possible under the same conditions as he would be if working in his own laboratory and within reach of a good chemical library The candidate who shines in the one will not necessarily shine in the other examination The university graduate is more qualified to talk and to teach, but the overcrowding of his curriculum leaves him little time in which to practise and acquire technical skill, without which the institute's qualification cannot be attained It is Prof Frankland said in conclusion, this practical character which must be preserved in the institute's examinations, so that fellows and associates may be known for the soundness of their judgment and for their capacity to perform chemical work upon which the public can place implicit reliance

SOCIETIES AND ACADEMIES

LONDON

Faraday Society, February 19 —Dr T Martin Lowry in the chair —The present position and future prospects of the electrolytic alkali and bleach industry J B C **Kershaw** The paper opens with a brief historical review The second part of the paper contains a list of the works now operating in Europe and America summarising, so far as information is available, power used, type of cell and process employed, and products made The totals show that about 55,000 h p are now being devoted to the production of alkalies and bleach by the electrolytic method, and that plant representing about 13,000 h p is lying in reserve Assuming that all the plants are being worked to the best advantage, the production of 70 per cent caustic soda at present would be about 110,000 tons per annum, with an equivalent of 231,000 tons of 35 per cent bleaching powder (2 tons of caustic and 4 2 tons of bleach per E H P year) In conclusion, the future of the industry is discussed

Royal Meteorological Society, February 20 —Dr H R Mill, president, in the chair —Report on the phenological observations made during 1906 by observers in various parts of the British Isles E **Mawley** The most noteworthy features of the weather of the phenological year ending November, 1906, as affecting vegetation, were the dry period lasting from the beginning of June until the end of September, and the great heat and dryness of the air during the last few days in August and the first few days in September Wild plants came into flower in advance of their usual dates until about the middle of April, after which time they were, as a rule, to about the same extent late Such early spring immigrants as the swallow, cuckoo, and nightingale reached these islands somewhat behind their average dates The only deficient farm crop, taking the country as a whole, was that of hay, all the others being more or less above average The yield of apples was about average in all but the north of England and in Scotland, where there was a very scanty crop Pears and plums were everywhere very deficient, whereas all the small fruits yielded moderately well As regards the farm crops, the past year proved even a more bountiful one than that of 1905 —The metric system in meteorology R. **Inwards**. Attention was directed to the advisability of adopting some uniform system by all the meteorological observers upon the globe

CAMBRIDGE

Philosophical Society, January 28 —Dr. Hobson, president, in the chair —Kanalstrahlen in helium. Prof **Thomson**.—An experiment with a pair of Robison ball-ended magnets G F C. **Searle**. A Robison ball-ended magnet AB is supported on a pivot O close to a drawing board, and a second Robison magnet CD, resting on the board, deflects AB If p_{AC} denote the perpendicular from O upon AC, the turning moment experienced by AB is the resultant of the four moments $mm'p_{AC}/AC^2$, $mm'p_{AD}/AD^2$, $mm'p_{BC}/BC^2$, and $mm'p_{BD}/BD^2$, where m is the pole-strength of CD and m' that of AB. If h_A, h_B be the perpendiculars from A, B upon the line A_0B_0, where A_0, B_0 are the undeflected positions of A and B, the moment due to the earth's magnetic force, H, is $m'H(h_A+h_B)$ Equating these results the value of m is found in terms of H and of the four distances AC . and the six perpendiculars h_A, h_B, p_{AC} These ten lengths are measured on the drawing board —A method of determining the thermal conductivity of India-rubber G F C **Searle**. Steam from a boiler passes through an india-rubber tube, part of the tube being immersed in water contained in a calorimeter Since the conductivity of india-rubber (0 00042) is small compared with that of water (0 0013), the temperatures of the inner and outer walls of the tube may be taken as equal to θ_1 and θ_2, the temperatures of the steam and of the well-stirred water in the calorimeter The conductivity K is found from the rate of rise of temperature of the calorimeter by the equation

$$K = \frac{M}{2\pi l(\theta_1 - \theta_2)} \frac{d\theta_2}{dt} \log_e\left(\frac{a}{b}\right),$$

where M is the water equivalent of the calorimeter and its contents, a and b are the external and internal radii of the tube, and l is the length immersed —A curvature method for measuring surface tension C T R **Wilson**. To measure the surface tension of mercury, a circular hole of about 1 mm in diameter is made through a glass plate closing the upper end of a vertical tube The tube is filled with mercury and sufficient pressure is applied to give a suitable curvature to the meniscus projecting into the aperture The curvature is measured by making the meniscus serve as a convex mirror A microscope is focussed (1) on the centre of curvature (when a reflected image of the eye-piece cross-wires will be seen in focus), (2) on a fibre stretched just above the meniscus, (3) on the virtual image of the fibre formed by the meniscus From the vertical displacements of the microscope between these three positions the radius of curvature is obtained If the pressure be changed by a known amount between two such measurements of curvature the surface tension can be deduced —The application of integral equations to the determination of expansions in series of oscillating functions H **Bateman**.

February 11 —Mr D Sharp, vice-president, in the chair —The mode of formation of the initial cell-wall, the genesis and neogenesis of the connecting threads, and the method of connection of living tissue cells Dr W **Gardiner**. Having summarised the existing theories as to the structure of the "initial-wall" of plant cells, and the current view expressed by Strasburger as to the development of connecting threads, the author stated that his own observations appear to prove that the above views are inadmissible —The ethnology of modern Egypt Dr C S **Myers**. The measurements, notes, and photographs taken in this investigation lead to the conclusion (1) that, compared with the "prehistoric" people of 5000 B C, the modern inhabitants show no sensible difference in head measurements or in the degree of scatter of individual measurements about their average; (2) that the modern Copts throughout Egypt are less negroid than the modern Moslem population; (3) that both the Copts and the Moslems in Upper Egypt are more negroid than those in Lower Egypt, (4) that from the anthropometric standpoint there is no evidence of plurality of race in modern Egypt —Notes on the structure and behaviour of the larva of *Anopheles maculipennis* A D **Imms**. The paper dealt briefly with the occurrence of the larva of *Anopheles maculipennis* in the neighbourhood of Cambridge, together with notes on its bionomics.

EDINBURGH

Royal Society, February 4.—Dr R H Traquair in the chair —The fossil Osmundaceæ R **Kidston** and D. T. **Gwynne-Vaughan**. The paper contained a description of two new species of Osmundites, collected from the Jurassic of Otago, N Z, by Messrs Dunlop and Gibb, after whom they have been named *Osmundites Dunlopi* differs from the hitherto described species in possessing a continuous ring of xylem which is not interrupted by the departure of the leaf-traces In *O Gibbiana* the xylem ring resembles that of the recent Osmundaceæ, and is broken up into a large number of separate strands The structure of two other species, *O Dowkeri* and *O skidegatensis*, was also described and compared with that of the new species Their discussion of the bearing of the structure of the fossils upon the anatomy of the order led the authors to regard the osmundaceous stele as derived from an ancestral protostelic type with a solid central axis It was consequently suggested that the Osmundaceæ were derived from the same ancestral stock as the Botryopteridæ.—The development of the anterior mesoderm and paired fin, with their nerves, in Lepidosiren and Protopterus W E **Agar** The pro-otic mesoderm is quite unsegmented The material from which the eye muscles are derived is, however, drawn from an extended source, probably representing the three anterior somites of van Wighe A study of the conditions in these fishes lends support to the view of Gegenbaur as to the segmentation of the head in opposition to those of van Wighe It seems probable that the latter's fourth pro-otic somite represents a fused mass of segments to which the whole of the branchial region morphologically belongs An extension of splanchic head structures backwards in relation to trunk myotomes actually takes place in the ontology of these forms The constrictor muscle of the pharynx is derived from two distinct sources, one splanchic from the walls of the pericardio-peritoneal duct, the other somatic from the occipital myotome v A separation of the hypoglossal and brachial plexures is brought about by the greatly distended pronephros separating the ventral processes of those myotomes which supply the hypoglossal and pectoral fin musculature respectively The pectoral fin is situated in front of the myotomes which supply its mesoderm, and posterior myotomes are gradually ceasing to contribute to its development The pelvic fin develops at the hind end of its innervation region Its position is subject to considerable individual variation, but this is always accompanied by a corresponding variation in the position of the cloaca —Scottish Tardigrada, collected by the Lake Survey James **Murray** Though found in Scotland nearly 150 years ago, the Tardigrada were totally neglected until recently the Lake Survey offered an opportunity for their study In the paper a summary is given of all that is known about Scottish Tardigrada The list contains forty-one species In the Scottish lochs thirty-one species have been found Most of these are of casual occurrence in lochs only two or three species being normal inhabitants of water About twenty species were noted in the Shetland Islands, a fact of great interest being the occurrence of a number of species hitherto known only from Arctic regions A number of new species discovered had the same limited distribution being known as yet only from Scotland and Spitsbergen or Franz Josef Land Seven new species and four new varieties were described —Arctic Tardigrada, collected by W S Bruce James **Murray** Richters had already noted twenty-four species of Arctic Tardigrada. Bruce's collections on various expeditions yielded twenty-eight species, bringing the total number of known Arctic species up to forty Three new species were described, and there were eight which had been recently discovered in Scotland There were fourteen species common to Scotland and some part of the Arctic regions Of the twenty-two species collected in Spitsbergen, twelve were new for that region Franz Josef Land was virgin soil and of the nineteen species found there, fifteen occur in Spitsbergen.—*Prymnothonus Hookeri*, Poisson pelagique de *l'Erebus* et de la *Terror* retrouve par l'Expedition Antarctic Nationale Écossaise Louis **Dollo**. The fishes collected on the voyage of the *Erebus* and *Terror* were not all brought home in safety The most interesting of these lost fishes were the Prymnothonus and the Pagetodes The latter, which is probably the same as the Cryodraco of the Belgian expedition, was eaten by the cat of the *Terror* A figure of *Prymnothonus Hookeri* was copied from a sketch by Hooker and published in 1841 by Richardson, who considered it to be a Murænoid allied to the congers The figure is reproduced by Günther in the eighth volume of his catalogue of the fishes in the British Museum, and he follows Richardson in his description Later, in his "Pelagic Fishes of the *Challenger*" (1889), Günther places Richardson's specimen third in a series of four small fishes A, B C, D, and says —"I have no doubt that all these specimens represent larval conditions of fishes belonging to Paralepis or Sudis or of genera allied to them That they all are stages of development of the same generic type of fishes is very improbable but the second and third specimens may well be considered to be the same type, which provisionally may be designated by the name proposed for it by Richardson" M Dollo, on the other hand, does not consider the *Challenger* specimens A and B to have anything to do with Prymnothonus, and regards specimen D to be a mature specimen of Richardson's fish He gives a rectified diagnosis of *Prymnothonus Hookeri*, Richardson from three specimens collected by the Scottish Antarctic Expedition and places the fish in the family Paralepidæ, in accordance with Günther's indications

PARIS

Academy of Sciences, February 25 —M Henri Becquerel in the chair —The president announced the death of M Moissan, member of the section of chemistry and gave a short account of his life-work —Certain algebraical surfaces related to Abelian functions of the third kind L **Remy** —Remark on waves of shock Application to the explosive wave M **Jouguet** For a wave of shock to be propagated, it is necessary that it should have a velocity higher than, or at least equal to that of ordinary waves in the medium which precede it and lower than or at least equal to, that of the ordinary waves which follow it Admitting this proposition, the author applies it to the interpretation of the phenomena of the explosive wave —Some properties of the explosive wave M **Crussard.** —The influence of temperature on absorption in crystals. Magneto-optical phenomena at the temperature of liquid air Jean **Becquerel.** At the temperature of liquid air the optical properties of crystals approach the properties of transparent vapours, the absorption bands contracting forming a line spectrum The author's interpretation of these results is that the period of the proper movement of the electrons is not influenced by temperature in solid bodies, but that the damping or the resistance to the particles in vibration increases and decreases with the temperature The magneto optic phenomena exhibited by xenotime and tysonite at the temperature of liquid air have also been studied —The theory of the formation of aventurine copper glass A **Auger** Experiments tending to show that the colour is due to the presence of copper silicate —Ethyl lactyl lactate F **Jungfleisch** and M **Godchot** A study of the products formed by the action of heat on ethyl ($d+l$) lactate These are analogous to those obtained by heating lactic acid, but the mechanism appears to be different in the two cases —The atomic weights a function of the position which they occupy in the series of their increasing value Adolphe **Minet** —The melting points and boiling points of aliphatic and aromatic hydrocarbons Gustave **Hinrichs.** A discussion of a recent paper of M Tsakalotos —The coagulation of the latex of caoutchouc and the elastic properties of pure caoutchouc Victor **Henri** The latex of india-rubber is a negative emulsion, and its coagulation can be compared with the precipitation of negative colloids A study of the conditions of coagulation leads to the conclusions that the coagulation of the latex by electrolytes is determined by the positive ions of the electrolytes, the structure of the coagulum varies with the nature and concentration of the bodies employed for the coagulation a feeble coagulant producing a pulverulent or flocculent precipitate, an energetic coagulant an elastic clot with a reticular structure The elastic properties of the india-rubber obtained depend

greatly on the nature of the coagulant employed, there being a distinct relation between the fineness of the reticular structure of the clot and the elastic properties —The presence of phenylethyl alcohol in the essence from the needles of the Aleppo pine of Algeria Emilien **Grimal** Details are given of the method of extraction and identification of the phenylethyl alcohol —The successive distributions of terpenic compounds in various organs of the living plant Eug **Charabot** and G **Laloue** —Fluorine in the shells of molluscs P **Carles** The presence of fluorine in the mollusc shells is proved if the shell is treated with hydrochloric acid, the presence of fluorine may be easily overlooked, since hydrofluoric acid is carried away with the carbon dioxide —A new genus of Pennatulidae Ch **Gravier** —*Gardia alata*, a new species J **Kunstler** and Ch **Gineste.**—Some physico-biological conditions of Lake Mélah, Algeria J **Bounhiol** —The toxic effects of oysters J **Baylac** Apart from the possibility of bacterial infection, the fluid of the oyster itself possesses toxic effects and these are greatly increased by keeping at a temperature of about 16° C for two or three days The author is of opinion that many accidents attributed to the bacterial contamination of oysters are really due to the increase in the toxic power of the natural fluids of the oyster under the influence of temperature —Do elephants possess a pleural cavity? Mme Marie **Phisalix** A reply to a recent note of M Giard —New researches on the transplantation of nerve ganglia, transplantation in the frog G **Marinesco** and J **Minea.** In cold-blooded animals the transplanted ganglion cells live for a much longer time after transplantation, and react and repair their lesions more readily than the ganglion cells of animals at constant temperature —The distribution of microbial secretions in a culture, between the liquid of this culture and the micro-organisms Free toxins and adherent toxins Extra cellular bodies and intra-cellular bodies MM **Charrin** and **Goupil** —A remarkable case of an aneurism of the ophthalmic artery cured by gelatin MM **Lancereaux** and **Paulesco** In the treatment of aneurisms of the aorta by gelatin injection the improvement although marked, proves to be only temporary, and the effect of each injection is less than that of the one preceding, no permanent effect being produced In the case described the cure was complete and permanent after thirty-nine injections

MODERN MOTOR VEHICLES

Motor Vehicles and Motors their Design, Construction and Working by Steam, Oil and Electricity By W. Worby Beaumont Vol ii Pp xvi+677. (London Archibald Constable and Co., Ltd, 1906) Price 42s. net

WHEN we reviewed the first volume of this work on the motor vehicle, we pointed out how difficult it is adequately to review encyclopædic matter, which in this instance occupies 660 pages of letterpress, accompanied by upwards of 400 illustrations Mr. Beaumont has, in this second volume, supplied many of the omissions and corrected some of the mistakes which existed in his first volume, so that now the two volumes, taken together, form a valuable work of reference, not only for the general public interested in the motor movement, but of considerable value to professional engineers

In this second instalment, after a short introduction pointing out the rapid development of motor engineering during the last two years, Mr Beaumont devotes the first half of the work to descriptive matter dealing with motor vehicles of all kinds commencing with the lighter motor-cars and going on to the heavier vehicles and electrically-propelled cars We do not propose to say much on this portion of the book No doubt those who are interested in any particular make of car will turn to the description of that car, but to the general reader the whole of this portion of the work savours of a dealers' catalogue, and is somewhat wearisome to read The few pages dealing with modern American vehicles show that these vehicles are interesting, as they depart rather more widely from the conventional types than is the case with the Continental and British-made cars

With chapter xxi the really interesting part of the book commences In this and the following chapters the author summarises the advances that have been made in the design and in the various components which are now accepted as the necessary features of a petrol-driven vehicle In chapter xxiii he gives us in a compendious form his methods of computing the h p absorbed in propelling motor vehicles, but we notice that on p 349 he repeats the coefficient for air resistance which he originally gave on p 49 of the first volume, namely, that the total air resistance of a vehicle varies as the velocity squared in miles per hour multiplied by the exposed cross-section of the car, multiplied by the coefficient 0.0017 It must be noted that this coefficient is only about two-thirds of the value of that which was obtained after careful experimental work at the National Physical Laboratory by Dr Stanton as that of flat-fronted solid bodies moving through columns of air the cross-section of which is very large in relation to the solid body that moves through them We think that although Mr Beaumont explains this low figure by the fact that it works in very fairly with his computations as to the actual h p exerted by cars of all classes, both in hill-climbing competitions and on speed trials up to 60 miles an hour it must be admitted that far more accurate experimental measurements must be made to ascertain whether this extremely low figure of 0.0017 has ever been approached by any form of solid moving through a column of air even in cases where great attention has been paid to the form of the solid, especially to the stern lines, to use nautical nomenclature It appears probable, therefore, that the table vi on p 350 is likely to need considerable correction

The author in chapter xxiv gives us very valuable and interesting notes on the influence of the vibration and even turning effort of the propelling engine on the stability of the car when it is driven rapidly round sharp bends of the road We think that in this chapter he is substantially correct in his views, and the matter is of great importance, and has hitherto not received sufficient attention from the designers of these vehicles

With chapter xxv he commences his descriptions of the heavier class of modern self propelled vehicles applied to commercial purposes such as the carriage of goods, omnibuses and other public-service passenger vehicles This part of the descriptive matter is very full, but from the nature of the subject is incomplete, as in no branch of the industry have there recently occurred such great changes, and these changes are likely to continue to occur as the type of public-service vehicle is yet very far from perfect, and is likely to be greatly modified in the immediate future, in fact, it is not too much to say that most of the vehicles described in chapters xxv to xxviii will be obsolete in a few years time, particularly when we consider the extraordinary results which are now expected from the adaptation to these vehicles of highly superheated steam produced in flash or semi-flash boilers, for although in chapters xxix to xxxi the author gives descriptions of the various forms of steam-driven cars made by Serpollet White, Turner-Miesse and Clarkson, and others, these really relate to the smaller class of pleasure car, and not to the public-service vehicle

Chapter xxxii which deals with the highly important and dangerous question of the skidding of self-propelled vehicles on our greasy streets, is disappointing, as the author gives no indication of the direction in which improvement is to be expected He does not even touch on the highly interesting matter of how much depends on the skill of the drivers and of the power rapidly acquired by them of controlling the side slip or skidding by a certain rapidity of action and correlation of hand and eye correcting the tendency to skid at the earliest stage, long before the brain has had time to consider the matter and to apply a corrective effort

The chapter devoted to carburetters is interesting as it shows that much ingenuity has been applied to this most important organ of the internal combustion engine, yet little or nothing has been done on the question of the day, namely, the utilisation of the heavier oils for these engines Until this is done

everyone who uses the petrol-driven motor-car is at the mercy of the kings of oil finance, who at present are masters of the situation

Another important matter, that of electrical motor vehicles, is dismissed in a single chapter, although, on account of the recent reductions in the cost of electrical energy the prospects of this class of vehicle are increasingly good

In the chapter devoted to the consideration of the efficiency of transmission gear, the matter is dealt with in an ingenious manner, and it is probable that the rough-and-ready method adopted by the author of calculating the transmission losses is within a narrow percentage of being correct The objects of the tourist trophy race initiated by the Automobile Club are clearly explained, and the cars taking part in the first of these races are tabulated and their performances usefully compared

Altogether, the author, in this second volume, has been very reasonably successful in dealing with the difficult task of getting together sufficient descriptive matter to satisfy any reasonable inquirer, and has made his matter as short as was possible considering that he has been compelled to describe a mass of vehicles the bulk of which resemble one another very closely, as most of the designers have copied the main features of two or three Continental models, and only vary in certain details or special methods of cheapening or facilitating manufacture

THE SOLAR RESEARCH UNION

Transactions of the International Union for Co-operation in Solar Research Vol i (First and Second Conferences) Pp 257 (Manchester University Press 1906) Price 7s 6d net

In a previous number of this Journal a brief summary was given of the proceedings of this International Union at its second conference, held at Oxford in September, 1905 The volume before us gives a complete historical account of the union from its origin in 1904 up to the end of the work completed at the Oxford meeting, and its appearance is due to the energy of the chairman, Prof Schuster who has brought all this useful material under one cover

The subject is dealt with under seven heads The first shows that the origin of this union was due to Prof George E Hale, who issued a circular letter to a number of men of science interested in solar physics The receipt of favourable answers led him to approach various societies and academies, with the result that a meeting was arranged and held in connection with the International Congress of Science at the St Louis Exhibition

Part ii deals with the proceedings of the first conference, which took place in September, 1904, and is followed by part iii, which contains *in extenso* the papers submitted to the conference They include introductory remarks by Prof Hale on the importance of international cooperation in solar research, and valuable reports by Henry Crew, A Pérot, C Fabry, H Kayser, and Lewis Jewell on the importance of establishing a new system of standard wave-lengths

In part iv we are made acquainted with the preparations for the second conference. A portion of this consisted in sending out circular letters to members of the union and others, relative to such subjects as the fixing of standards of wave-length, measurement of the intensity of solar radiation, work done with the spectroheliograph, and the spectra of sun-spots In response to these, numerous valuable replies were received, and these are all included in the volume

At the Oxford conference some important papers were communicated (part vi), among which may be mentioned the compensating pyrheliometer, by K Ångstrom At this conference the constitution of the union also was discussed, and we have in this volume (part viii) the text in English, French, and German of the constitution as finally adopted, and the resolutions, also in the three languages, concerning the various important questions discussed

An important result of the Oxford conference was the appointment of committees to take in hand the work of preparation and organisation of investigations which have not yet been collected and co-ordinated

In connection with these, the present volume contains a very valuable memoir, drawn up by Prof Fowler, on the observations of the spectra of sun-spots in the region *b* to F (part vii) This paper brings together in a very admirable manner the main features of the spectrum-analysis of sun-spots, and will serve as a valuable guide to those observers who take up this part of solar physics

The next meeting of the union will take place at Meudon in May of the present year There is every probability, therefore, that a second volume of these transactions will make its appearance during the next twelve months

AGRICULTURAL ANALYSIS

The Principles and Practice of Agricultural Analysis By Dr H W Wiley Vol i Soils Second edition, revised and enlarged Pp xii+636 (Easton, Pa Chemical Publishing Co, London Williams and Norgate) Price 18s net

Dr WILEY'S treatise on agricultural analysis has long been the chief resource of every worker in that domain, because it contained not merely the particular method in vogue, but to a large degree all the methods that had been proposed or were in use in either American or Continental laboratories, very often in the words of the original This did not make the book easy to use by the tyro, for Dr Wiley rarely attempted any criticism or recommended one method beyond another, but the collection was extremely useful to the investigator, and saved him much labour in trying over things which had been tested before The gain is particularly apparent in dealing with soils, the subject of the present volume, for the analysis of a soil is not like that of a manure, where there is a definite element or elements to be

determined and a result in sight the correctness of which is only limited by the imperfections of the method. Instead, the methods are often conventional, depending upon such factors as the method of preparing the sample or the solvent employed, or they may be determinations like the absorptive power of the soil for water, which have no absolute meaning at all, but are merely attempts in the laboratory to get a number which shall represent the behaviour of the soil in the field. With regard to so many of these determinations of a physical nature the difficulty lies, not in carrying out the process, but in interpreting it afterwards, and correlating it with some practical aspect of the soil. The present volume of Dr. Wiley's book becomes in consequence, something more than a collection of analytical methods, it is in many respects a treatise on soil chemistry and soil physics, so full are the introductory discussions dealing with each of the various means of investigating the soil, and as such it is indispensable to all serious students of agricultural chemistry.

Dr. Wiley has cut out some of the matter of the earlier edition, though retaining processes which have a historical interest or are necessary in tracing the development of the more modern method, he has further incorporated methods and investigations which have been published in the twelve years that have elapsed since the appearance of the first edition. The present volume is dated October, 1906, we miss, however, one or two methods which appeared before that date, *e.g.* Mitscherlich's interesting determination of the heat evolved when a soil is moistened (benetzungswärme), which is correlated with the active surface of the soil particles. In one or two other respects also we think later work might have modified some of the conclusions expressed, but of course the subject is in a constant state of progress, and the time occupied in writing a book of this magnitude is sufficient to bring about a revision of some of the points of view. We notice, indeed, but scant reference to the more recent developments in soil investigation which have issued from the Division of Soils in the United States Department of Agriculture, perhaps we may take this negative attitude of Dr. Wiley's as a critical one.

In conclusion, we can only express our thanks for what must always be one of the most useful books in the library of any agricultural laboratory.

A. D. H.

OUR BOOK SHELF

Introduction to the Theory of Fourier's Series and Integrals and the Mathematical Theory of the Conduction of Heat. By H. S. Carslaw. Pp. xvii+434. (London: Macmillan and Co., Ltd.) Price 14s. net.

THIS book is an interesting sign of the times. The gulf between pure and applied mathematics, in this country at any rate, has of recent years become more and more complete. Indeed there is no one who so heartily detests and despises mathematics proper as the ordinary physicist. He is often compelled to use elaborate mathematical analysis, but he does not feel or profess any interest in anything but the result, and questions as to the mathematical basis of his arguments seem to him merely trifling and vexatious.

Prof. Carslaw has therefore shown a good deal of courage in offering to English readers a book on the theory of conduction of heat which includes a serious account of the mathematical difficulties of the theory and may expose him to unsympathetic criticism from different points of view which have little in common. However, the experiment is a distinct success, and it is to be hoped that it will lead to similar and equally successful experiments with other and more difficult branches of mathematical physics.

The book is divided into two parts. Part i. is entirely mathematical, and it is this part which contains most that is novel in an English book, and is, therefore, most interesting to the critic. A short but well-written historical introduction is an attractive feature. In the first two chapters, which deal with irrational numbers and infinite sequences in general, the author mostly follows Dedekind and Tannery, and he could not have chosen better guides. The chapters on uniform convergence are also good, though here the arrangement and method of presentation do not seem to us in every respect the best. The author, we are glad to see, speaks of "*infinite* definite integrals" and discards the barbarous "improper." He might perhaps have brought out more clearly the fact that the infinite integral is essentially a repeated limit—as it is, he rather exaggerates the analogy between the integral and the infinite series, and it is a pity that he should have omitted to prove the fundamental inversion theorems for finite integrals. But the chapters dealing especially with Fourier's series seem to us the best; we are particularly glad to see Fejér's theorem included. Part ii. contains a clear account of the principal problems of conduction, and requires no special comment here.

This book shows very clearly how much of the Continental spirit of rigour English mathematics has absorbed in recent years. It also shows how much the heaviness of the Continental δ and ϵ can be lightened by a bright and attractive style, interesting illustrations, numerous examples, and other touches of the Cambridge tradition.

G. H. H.

Museu Paraense de Historia e Ethnographia. Arboretum Amazonicum. By Dr. J. Huber. Pp. 40, with 40 plates. Decades i. to iv. (Para, 1900 and 1906.)

FOR a development of moist equatorial vegetation no region surpasses that bordering the Amazon and its tributaries, which Dr. Huber, in the course of his long association with Para, has had unique opportunities of visiting. The form in which Dr. Huber presents his information is similar to the "Vegetationsbilder," where the illustrations are the chief feature and the notes are explanatory thereto, but it should be stated that the first two parts of the "Arboretum Amazonicum" were issued in 1900, previous to the first numbers of the "Vegetationsbilder." Two additional parts appeared last year, and it is proposed to complete the work in ten numbers. The publication of the work has been undertaken by the Polygraphisches Institut of Zurich, and the photogravures afford a criterion of the excellence of their work.

Palms generally rank among the most important tropical plants, and along the Amazon and its tributaries, especially near the embouchure, they form such prominent objects in the landscape that all voyagers make special mention of their luxuriance and variety. Dr. Huber devotes a number of plates to different species: *Phytelephas microcarpa*, that yields vegetable ivory, the Tucuma and Mumbaca palms, both species of Astrocaryum, the Javary, another species of the same genus, bearing spines on the young trunks, and the Bussu, *Manicaria saccifera*, producing huge, almost entire, leaves, are illustrated in the first two parts. No less interesting are *Cocos inajas*, with pinnæ arranged in bundles on the leaves, the Baccaba or wine-palm, *Oenocarpus distichus*, remarkable for the distichous arrangement of the leaves, and the Urucury, *Attalea excelsa*, which provides the *Seringueiro*, or rubber collector, with nuts used in smoking the rubber. Of trees other than palms, the famous Para rubber tree, *Hevea brasiliensis*, *Dipteryx odorata*, the source of the Tonca bean of commerce, *Bertholletia excelsa*, the superb tree yielding brazil-nuts, and the magnificent *Caryocar villosum* are selected for representation.

Dr. Huber has also chosen some illustrations of typical plant formations, including the littoral vegetation on the river Couany, where the Aninga, *Montrichardia aborescens* is growing on the shore, scenes from some of the tidal creeks or channels known as "igarapés", plant formations occurring in inundated localities, showing in one case a fine development of *Ipomoea fistulosa*, in another a wide expanse of *Panicum amplexicaule*, and a view of an Indian plantation with manioc and sugar-cane in the foreground, and the characteristic Imbauba, *Cecropia peltata*, beyond.

The illustrations are admirable, owing to the care that has been exercised in selecting fine specimens and suitable situations from which the characteristic features of the plants can be brought into the photographs.

Cams, and the Principles of their Construction. By George Jepson. Pp. 60. (New York: D. van Nostrand Co.) Price 8s. net.

IN this work examples are given of the design of cams of various types, including cylindrical, conical, face and spherical cams, and of different degrees of complexity from the simple heart-shaped cam employed in winding bobbins to the writing cam with the differential motions of paper and style. The illustrative drawings are accurately and beautifully executed, the construction lines being printed in red ink for the sake of extra clearness. It is shown how to design the profile of a cam so as to give a simple harmonic motion or a uniform acceleration and retardation to the follower, thereby effecting a change of position of the latter with a minimum wear and tear. The book is a welcome addition to the somewhat scanty literature on the subject.

Rivetage. By M. Fricker. Pp. 168. (Paris: Gauthier-Villars and Masson et Cie., n.d.)

THIS little volume belongs to the "Encyclopédie scientifique des Aide-mémoire" series, to which attention has often been directed in these columns. It is divided into two parts, the first passes in review the rules—for the most part empirical—which are adopted in determining the dimensions of rivets and in riveting generally, and the second describes the methods which are employed in the actual processes of riveting.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A New Mud Volcano Island.

ADMIRAL FIELD'S letter in NATURE of February 28, embodying Commander Beauchamp's description of a new island recently discovered by him about nine miles northwest of Cheduba (not Chebuda) Island, off the coast of Arakan, leaves no room for doubt that the island in question was due to the eruption of a submarine mud volcano.

Ramri and Cheduba, together with the adjacent subordinate islands, are composed mainly of shale and sandstone (probably of Tertiary age), containing some coal, and also very considerable quantities of petroleum, accompanied by inflammable gas. There is evidence of a certain degree of abnormal subterranean heat, although such is far lower than that associated with true volcanoes, which do not exist, nor have any volcanic rocks been observed. Mud volcanoes are fairly numerous, which, besides emissions of a quieter character, are subject, at uncertain intervals, to violent paroxysmal eruptions. At such times mud and stones are shot out with great force and noise, accompanied by large quantities of inflammable gas, which in many cases catches fire and gives rise to a volume of flame that lights up the country for miles around. There are numerous well authenticated descriptions of such occurrences, more than one of which were submarine. The stones ejected are all derived from the stratified rocks mentioned above, the shales furnishing the source of the mud. Electric sparks produced by the friction of the ejecta amongst themselves probably cause the ignition of the gas. Some of the recorded paroxysms were synchronous with earthquakes.

A somewhat detailed account of the mud volcanoes may be found in the "Records of the Geological Survey of India," vol. xi. (1878), pp. 188–207, and descriptions of several later eruptions in subsequent volumes.

Ealing. F. R. MALLET.

A New Chemical Test for Strength in Wheat.

THE principle of the test for strength in wheat flour described as new by Mr. T. B. Wood in a recent issue of NATURE (February 21), and further claimed by Dr. E. Frankland Armstrong (NATURE, March 7) as having been in regular use in his laboratory during the past year, was employed by me more than four years ago, and still forms an important factor in my physicochemical method of gauging the baking qualities of wheat flour.

I can fully corroborate Mr. Wood's opinion that no single factor is capable of measuring the strength value of wheat, and Dr. Armstrong's statement that the problem is one in which no small number of variables must be dealt with.

In 1905 Mr. A. E. Humphries supplied me with five samples as tests of the accuracy of my system as then elaborated. I was, however, not successful, but, on receiving Mr. Humphries' views of their baking qualities, the cause of my failure was at once apparent. When investigating the relation of chemical composition to baking qualities I had relied for the latter data upon loaves baked in tins, whilst Mr. Humphries based his opinions upon self-supporting loaves of the "cottage" type. It thus became evident that it was necessary to view the analytical data from a standpoint suited to a definite system or method of baking. That different systems of baking require different types of flour explains why millers occasionally receive both commendatory and condemnatory remarks from their customers on the quality of the same blend of flours.

I hope soon to have an opportunity of publishing some of the results of my investigations of the correlated factors determining the blending qualities, strength, and texture properties of wheat flour.

After a very lengthy investigation of the biochemical changes which occur in the natural ripening of the wheat berry, its preparation or "conditioning" in the mill, and the influence of variations in the treatment of the resulting flour in the bakehouse, I am fully convinced that it is no longer the bakehouse that has to give the final verdict on the qualities of flour, as laboratory methods can now provide all the data necessary for inferring the antecedent conditions, defining the present qualities, and anticipating the future evolution of wheat or its product flour

Waterloo, Liverpool, March 11

Ionisation and Anomalous Dispersion

IN NATURE of February 21 Prof Wood, referring to my letter of January 17, says that the effects observed were probably due to disturbance of the density gradient of the sodium vapour caused by "local heating by the wire" I am afraid that in my letter I cannot have described the experimental arrangement sufficiently clearly, at any rate Prof Wood seems to be under a mistaken impression

The wire was merely an electrode insulated from the tube containing the sodium vapour, but connected to one pole of a battery, the other being connected to the tube A current passed through the sodium vapour, or the nitrogen left in the tube after exhaustion and heating, presumably an ionisation current and this was of the order of one microampere, and could hardly produce much local heating

Be this as it may since I left Aberystwyth my pupil Mr Needham noticed an effect which if confirmed, appears to me to be decisive in favour of a connection between ionisation and dispersion While the tube was heated, by a flame as usual with 10 volts there was a current of 4 divisions and an anomalous dispersion of 9 divisions On raising the voltage to 58 volts the current rose to 10 divisions but the *anomalous dispersion immediately fell to zero* and thereafter slowly increased to a value somewhat greater than before

That an increase of current and presumably of local heating if there be any should diminish the dispersion temporarily can hardly be understood unless the systems producing the dispersion are themselves electrically charged and swept away to the electrode I hope shortly to investigate the whole question fully so as to decide definitely what connection, if any, exists between ionisation and dispersion

The Rusting of Iron

IN NATURE of February 21 (p 390) Prof W R Dunstan states that rusting of iron takes place in the presence of water and oxygen when every trace of carbonic acid has been removed To a certain extent this is the result obtained by our chemist but his experiments proved conclusively that rusting must be due to an admixture of carbonic acid for with improved precautions against its presence rusting was enormously reduced, and this is important, confined to one or two spots In some cases this local rusting took place where the steel samples rested on the glass vessels and it was but natural to suppose that this local corrosion was brought about by silicic acid of the glass The obvious precaution was to arrange an iron bowl in the centre of the glass vessel into which water could be distilled, but although this apparatus was constructed, it was not used because if corrosion can be caused by the silica of the glass, then it may also be caused by specks of exposed slag in the iron or by the oxidised specks of manganese sulphide which can be seen with the microscope or by other impurities Corrosion may even be brought about by carbonic acid occluded in the iron In order to settle the question the experiment should be repeated with a piece of iron of absolute purity

Manchester, March 5

A Problem in Chance

THE law of probability is often illustrated by the simple method of supposing a bag filled with an equal number of white and black balls which are presumably uniformly distributed within the bag It is stated that the chances are equal that any extracted ball will be black or white

I am desirous of ascertaining how this equality of extraction of either colour would be disturbed if it be assumed that the balls are not merely inert, but that there is an inherent tendency for like-coloured balls to cluster together Two subsidiary and mutually alternative conditions may be further assumed either the tendency of the black balls to cluster together is greater than that existing between the white balls or it is equal It is the former of these two subsidiary conditions that interests me

Perhaps I may state the problem in more definite form Assume 2000 balls, of which half shall be black and half white placed in a bag The intensity with which the latter tend to cluster = d and that of the former is greater, but to a less degree than half as much again The balls are extracted in groups of eight In four separate extractions what will be the probable proportion of black and white balls at each extraction? And how many extractions will have to be made before it is probable that an equal number of black and white balls will have been withdrawn?

GEO P MUDGE

London Hospital Medical College

THE UNIVERSITY OF THE CAPE OF GOOD HOPE

ON the invitation of Sir Lauder Brunton a meeting took place at his residence on January 21 of gentlemen interested in university education Among those present were Sir Arthur Rucker (of the London University) Dr Donald MacAlister (then of Cambridge University and president of the General Medical Council), Prof Perry (Royal College of Science) Sir W Arbuckle (Agent-General of Natal) Sir David Gill Sir John Buchanan and Mr Howard d'Egville honorary secretary Imperial Federation (Defence) Committee Prof Osler (of Oxford University), Sir Norman Lockyer K C B Sir Thomas Fuller (Agent General for Cape Colony) and Prof Stirling dean of the medical faculty of the Victoria University, were unfortunately prevented from attending Copies of the proposals provisionally agreed to by the committee of University of the Cape of Good Hope, relative to the re-organisation of that University had been circulated before the meeting and formed the basis of the evening's discussion The result was a consensus of opinion on several leading issues which may be summarised as under

(1) That in the existing condition of South Africa the interests of the higher education of the country would best be served by the continuance of only one examining and degree-conferring university

(2) That the conferring on single colleges in the country the power of granting degrees to their own students would be detrimental to higher education and specially injurious to the status of all such South African graduates Such degrees would be depreciated, not only in the estimation of the people of the country itself, but also outside the colony, and would not have the same value or consideration given them which degrees granted by one general University would receive The tendency of multiplying degree-granting institutions in the circumstances such as those existing in South Africa would be in the direction of unhealthy competition which would inevitably lower and not raise the worth of degrees so obtained

(3) That sound education would be promoted by associating in examinations the teacher with independent examiners, but the University should control all

examinations, and alone determine the granting of degrees. The appointment of examiners outside the influence of local institutions is desirable, so as to secure confidence in the impartiality of the examination, examiners of experience in teaching the subjects in which they examine should be employed. Efficiency, as well as confidence, would further be secured by obtaining as presiding members of each board of studies examiners experienced in teaching in institutions in the older centres of education.

(4) That all colleges should be affiliated with the University, and should be directly represented on the University council, if necessary larger representation being given to the larger institutions.

(5) That in any new Act of Incorporation or new charter provision should be made so as to leave the University free to expand, and to include new teaching bodies, as well as to develop in any direction in which the progress and prosperity of the country might in the future indicate.

AN ANTHROPOLOGIST AMONG THE TODAS.[1]

DR. RIVERS has re-discovered the Todas. This curious little nation, long known to us as an isolated social abnormality, in which the dairy industry takes the place of religion and matrimonial safety is found in a plurality of husbands, now appears to be both much more and much less than this. As a descriptive monograph in ethnology the book is a remarkable achievement, but it is, perhaps, most significant on account of its method. The social sciences are at a disadvantage in that they are not exact, as physical and mathematical sciences are exact, but the present work is a proof that anthropology is attaining such exactness as the nature of the subject allows. This means a good deal, as anyone may see who compares the present monograph with the earlier accounts of the Todas. The testing of the evidence and the verification of fact have been carried out in the most pertinacious and patient manner, and the general method followed is new enough in its application to deserve the epithet original. To the superficial reader little trace of this laborious preliminary process may be revealed, but the work will justify itself by remaining unsuperseded. It struck me as interesting that the account is compiled in such a way as to show itself in the making, that it is an organism, revealing its own evolution.

The Todas are sufficiently isolated as to render the problem of their origin more or less insoluble. Dr. Rivers makes a very good case, of the cumulative sort, for their *provenance* from the Malabar races. There are some interesting clues leading us back to the Christianising of South India more than a thousand years ago.

In their social organisation, the new facts collected by Dr. Rivers make our knowledge of the Todas practically free from lacunæ. To the comparative student this very full and detailed account will serve, among other things, to connect the sociology of India with that of the rest of mankind. The polyandrous character of marriage, and the customs of *terersthi* and the like, deserve studying in these pages by anyone who takes an interest in the marriage problems of Western civilisation. The Toda view of morality in this sphere merits consideration, especially in connection with the altruistic emotions. Something similar has been recently observed by Messrs. Spencer and Gillen among the natives of Central Australia. Not least remarkable is the way in which their form of marriage seems actually to make for efficiency and righteousness.

The chief regulations of the marriage system are in brief:—Prohibition of intermarriage between the two "castes" *Tartharol* and *Teivaliol*, exogamy among the clans which compose these "castes", certain kinship prohibitions, polyandry the typical form of marital association, the extra husbands being generally brothers of the husband proper, polygyny now on the increase either in the ordinary form, or two men having two wives in common, the transference of wives from one group of husbands to another, *terersthi*, a sort of concubinage, as between members of the two great "castes," *mokhthoditi*.

Fig. 1.—The 'Palikartmokh' saluting the threshold of the dairy at Kiudr 'Pavnersatiti'. From "The Todas."

We are supplied with a wealth of detail, practically new, in all the spheres of social life and religious practice. The economic sources of religion are more clearly laid bare in the full description of the dairy-religion of the Todas than would have ever appeared possible to the *a priori* speculator in anthropological theory. To quote Dr. Rivers:—"The sacred animals are attended by men especially set apart who form the Toda priesthood, and the milk of the sacred animals is churned in dairies which may be regarded as the Toda temples, and are so regarded by the people themselves. The ordinary operations of the dairy have become a religious ritual, and ceremonies of a religious character accompany nearly every important incident in the lives of the buffaloes." It would be a pity to attempt to skim the cream from the rich supply presented here; the reader will find it deeply interesting, and the student of religious origins will be well advised to ponder the whole subject. The best photographs in a well-illustrated book represent the operations of these milkmen, priests and

[1] "The Todas." By W. H. R. Rivers, Fellow of St. John's College, Cambridge. Pp. xviii+755; with illustrations and tables. (London: Macmillan and Co., Ltd., 1906.) Price 21s. net.

acolytes, the shrines and the divinity thereto attached It is interesting to note that the people would talk about an important ti "in exactly the same kind of way that an Englishman talks about a benefice "

FIG 2—Toda man From "The Todas"

The European cleric and the Toda *palol* thus meet after a journey commenced at what widely separated points Thanks to Dr Rivers's energy and care we have a complete and scientific account of one of the most significant phenomena in the history of that varied organism, religion

The author is of opinion that the division of the people into *Teivaliol* and *Tartharol* is due to the coalescence of two tribes, coming to the hills at different times There are marked dialectical differences between them The Toda language as a whole is very difficult The philologist will find it well worth study, and the data are both extensive and rendered more valuable in a way because the collector was himself ignorant of any other Dravidian tongue, and had therefore no expert prejudices The secret and sacred languages are rather conspicuous in the life of the Todas

The book—Dr Rivers' first book, if I mistake not, in this subject—is a monument of industry and care, not without insight and the results of comparative study, and is an invaluable record of which Cambridge and the new anthropology may be proud

A E CRAWLEY

A LAW OF RECORD TIMES IN RACING

A REMARKABLE article on "An Approximate Law of Fatigue in the Speeds of Racing Animals," by Mr A E Kennelly, appears in the Proceedings of the American Academy (vol xlii , p 275) for December, 1906 We cannot help speculating as to the causes which led the author to choose such a subject for investigation To the man of science, even to the omnivorous statistician, the subject sounds so unpromising—one may almost say undignified or improper, the sort of subject with which no civil servant, no permanent official, should ever deal, even in secret Once the investigation was commenced, it was naturally extended from one series of records to another, but what accident prompted the commencement? Mr Kennelly is provokingly silent on the point He opens, it is true, by telling us that "Olympia and Epsom Downs are known to fame by the races they have witnessed Olympian races, recently revived, are of international interest

A reduction of either of the records [for the 100 yards or the mile] by even one per cent would be a matter of world-wide importance, and the hero of the new record would be famous among the inhabitants of the temperate zones " Yet we find it hard to believe that the investigation was undertaken simply as a definite matter of urgent public importance, even though the results, as it turns out, may have the gravest social consequences They may lead to the advertising of mathematical tables and squared paper in the sporting press They may even influence the teaching of mathematics in our public schools, our universities, and other haunts of ancient peace

Put briefly and in its simplest possible form the approximate law relating distances with record times which Mr Kennelly has discovered is as follows —For all pairs of distances in the same proportion the record times are in constant ratio and this ratio is independent of the animal and of the mode of progression The observed ratios fluctuate, as one might expect, but the fluctuation seems to be of a casual kind over a very wide range of distances, and the ratios for different animals or modes of progress show little more divergence than the ratios for the same animal and the same mode of progress Thus, taking merely a few instances in the ratio 2 1, we have —

HORSES TROTTING

Distance (miles)	Time (seconds)	Ratio of times
1	118 5	—
2	257 0	2 16
4	598 0	2 33
5	750 75	—
10	1575 0	2 10
20	3505 0	2 22
Average ratio		2 202

MEN SWIMMING

Distance (yards)	Time (seconds)	Ratio of times
25	12 2	—
50	24 6	2 02
100	58 0	2 36
200	140 0	2 42
400	297 0	2 12
800	628 0	2 12
Average ratio		2 208

The law has been tested and found to hold good for horses running trotting, and pacing, and for men walking, running, rowing swimming, and skating It does not hold, on the other hand, for bicycling a not unnatural result, when the importance of the machine as well as the rider is considered [1]

If T denote the record time and L the distance, the law may evidently be put in the form

$$T = A L^{n} \qquad (1)$$

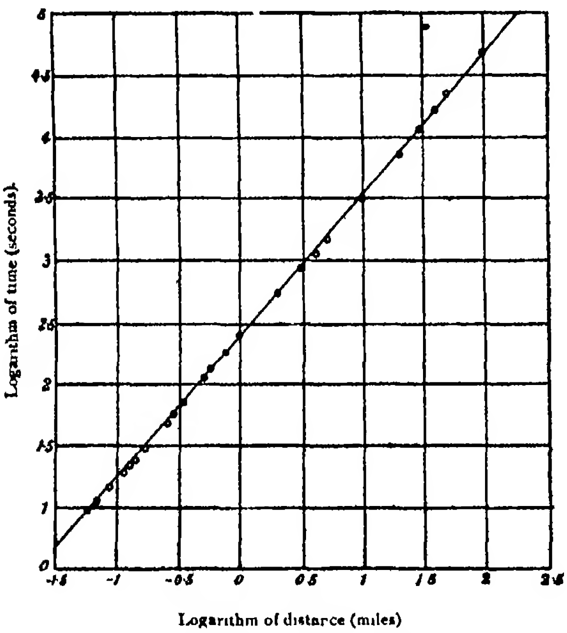
[1] Cf the work of M Bouny (Paris Academy of Sciences, and NATURE, vol liv , 1896), and R E Crompton (NATURE vol lxi 1899)

where n is a constant and A varies with the animal and the mode of progress. That is, in terms of logarithms,

$$\log T = \log A + n \log L \qquad (2)$$

Hence, if T and L are plotted on logarithmic paper, or their logarithms plotted on ordinary scale paper, the points obtained will lie more or less closely round a straight line. If a line be run as near as may be through the points, its slope will give the value of n. This is the procedure adopted by Mr. Kennelly, and he finds an average value of n equal to 9/8, corresponding to a ratio of the times for double distances 2·181. To illustrate the closeness of the logarithmic law from data that are readily accessible in England, we have plotted a diagram from the table of running records in "Whitaker's Almanack" (p. 415), taking, like Mr. Kennelly, the lowest record, whether amateur or professional, in each case. We must refer the reader to the original paper for numerous diagrams, on a somewhat larger scale, illustrating the records in the other cases.

The author concludes, we think correctly, that a



Men running: logarithmic graph of record time and distance, 100 yards to 100 miles.

record is more likely to be lowered if it correspond to a point lying above the time-distance line than if it correspond to a point lying below it, and hence the graph may be of service to the athlete. He also argues that, as a consequence of the law, an athlete should adopt such a speed in running that he can just maintain it constant to the end of the course and is then completely exhausted. But the energy of the individual is not exhausted suddenly in this way, and, although the conclusion may concur with practice, we do not think that it follows from the given law of record speeds. We agree with the author that more information is wanted on this head. It seems doubtful, in fact, if the observed rule should be termed a "law of fatigue" at all; it is not a law of the variation of speed, with time or distance, for the same individual running his fastest continuously, nor even of the average speeds of the same runner over different distances when he knew in advance the distance to be run. It is a law relating times to distances when the best possible runner is selected for each particular distance. This involves the adaptation of the individual as well as fatigue. How much it involves adaptation or selection is illustrated by the complete disagreement of the older with the more recent records for the case of trotting horses. For the longer distances only old records are available, and these fit much better with the older records for short distances (cf. *Encycl. Brit.*, xii., 205) than with the more recent records given by Mr. Kennelly.

We cannot help hoping that a knowledge of "Kennelly's Law" will soon be widely diffused, the possibilities of its educational influence seem almost unbounded. The bookmakers will take to studying "Chambers' Tables", betting books will be bound up with a few pages of logarithmic paper for the purpose of entering, shall we say, "recordograms", and Jones Minor, callous to the beauties of logarithmic graphs when illustrated by the laws of steam or the behaviour of purely symbolic barges on non-existent canals, may awaken into something resembling life when racing records are in question. Schoolmasters need not hesitate for fear of corrupting youth, the necessary data can be taken from either of those most respectable publications, "Whitaker's Almanac" and the "Encyclopædia Britannica."

G. U. Y.

PROF. H. W. BAKHUIS-ROOZEBOOM.

CHEMISTS have received with great sorrow the news of the death of Prof. H. W. Bakhuis-Roozeboom on February 8. Roozeboom was struck down in full activity, and science might have hoped to have been enriched by his work for years to come. At the beginning of February, however, he was attacked by influenza; apparent recovery was followed by pneumonia, which in three days proved fatal. He leaves a widow and five children.

Hendrik Willem Bakhuis-Roozeboom was born on October 24, 1854, at Alkmaar, a little town some twenty miles north of Haarlem, noted in history for the first successful resistance made against the Spaniards in the struggle for Dutch independence. He was educated in his native town at one of the higher burgher schools, where so excellent an education on modern lines is given. Even during his school career his unusual ability gave promise of a notable future. After leaving school he assisted his chemistry master, Dr. Boeke, for some time in making a number of soil analyses in connection with the plan which is still under discussion of draining the neighbouring Zuider Zee. Not thinking at first of an academic career he accepted a position in the butter factory of Dr. Mouton at the Hague, and it was the circumstance of the factory being burnt down in 1878 which decided his future. Hearing of the fire, a brother-in-law of Dr. Boeke, van Bemmelen, professor of chemistry at Leyden, offered Roozeboom the post of assistant. This he decided to accept, and while thus occupied he carried on his studies in the University of Leyden, and graduated in 1884. He remained at Leyden as docent, and later as lecturer, supplementing his small university stipend by teaching in the girls' higher burgher school and by translating English books into Dutch, until on the removal of van 't Hoff to Berlin in 1896 he succeeded him as professor of general chemistry in the Uni-

versity of Amsterdam, and this chair he held until the time of his death.

In the Dutch universities seven years is the minimum period of study required for graduation, and the last of these is devoted to original research. The work undertaken by Roozeboom on the hydrates of the halogens and their hydrides led him at once to the problems with which his name will always be associated.

In the course of his experiments he came upon phenomena which he was unable to explain. At that time the conditions which determine equilibrium in chemical systems were little understood by chemists. About ten years before, the American physicist Willard Gibbs, had developed a theory of equilibrium between materials in contact which was completely independent of all assumptions as to the nature of matter or as to molecular structure. Given a system constituted of homogeneous portions (phases, as they are called, P in number) separated from each other by definite surfaces of contact, and made up of constituents (components, as they are termed, C in number) the amounts of which present in the system can alter independently of the others, Gibbs had shown that, considering only the temperature and pressure under which the system exists and the concentration of the components, the number F of the latter conditions (degrees of freedom, as they are called) to which arbitrary values must be assigned to describe the system perfectly are given by the expression $F=C-P+2$, this numerical relationship being known as the "phase rule."

Gibbs had published his results in a journal not widely circulated—the Transactions of the Connecticut Academy. They were, moreover, presented in a mathematical form unfamiliar to chemists, and had consequently remained scarcely noticed all these years. Prof. van der Waals, to whom Gibbs's work was known, hearing of Roozeboom's difficulty, suggested to him that this mode of regarding equilibrium might throw light upon it. Roozeboom's philosophical mind at once grasped the immense possibilities of this new method of regarding problems of equilibrium, and from that time he occupied himself with brilliant success in working out its application to chemistry.

The investigations of Roozeboom and of those whom he interested in this branch of physical chemistry have cleared up our ideas in a surprising way, and opened out fresh paths of inquiry in the attractive region which connects chemistry and physics. The great merit of first applying the phase rule in chemistry must be attributed to Roozeboom, and gives him a high place among the founders of the new chemistry.

An account of the many applications of the phase rule to chemical problems was written by Roozeboom in his well-known book "Die heterogenen Gleichgewichte vom Standpunkte der Phasenlehre," of which two parts only have yet appeared. He had prepared all the necessary material, and was about to begin writing the third and concluding part at the time of his death.

Apart from scientific work his life was uneventful. His simplicity of character and extreme desire to do justice to every fellow-worker won him the affection of all who came to know him well. In 1890 he was made a member of the Royal Academy of Science of Amsterdam. Totally devoid of any trace of the advertising spirit, he received fewer public honours than might have been expected to follow his notable achievements, and everyone must feel regret that the scientific world did not in his lifetime more adequately recognise his services.

F. D. CHATTAWAY.

NOTES

THERE is every likelihood that Lord Lister's eightieth birthday, on April 4, will be suitably celebrated by his friends and admirers. A committee is being formed consisting of representatives of medicine and science with a view to carry into effect a suggestion made, we learn from the *British Medical Journal*, by Dr. C. J. Martin, F.R.S., the director of the Lister Institute. Dr. Martin has proposed that the best form in which to convey to Lord Lister the admiration and regard of his fellow-workers and followers would be the re-publication of all his scientific papers prefaced by a biography of Lister containing an account of the part he took in the development of present knowledge of infectious processes and of his efforts to avoid wound infection, the successful result of which revolutionised surgery. Dr. Martin will be glad to receive at the Lister Institute, Chelsea Gardens, S.W., the names of persons who desire to participate in this happy idea.

Science announces that the Rumford medal of the American Academy of Arts and Sciences "for discoveries in light and heat" has been awarded to Prof. E. F. Nichols, of Columbia University.

THE death is announced, in his seventy-fifth year, of Sir Thomas Hanbury, K.C.V.O., at one time of Shanghai, the founder of the Hanbury Botanical Institute at the Royal University, Genoa, and of the Museum Prehistoricum, near Mentone.

WE learn from the *Athenaeum* that the third congress of the Prehistoric Society of France will be held at Autun on August 13–18. Excursions will be made to Macon, to Mont-Auxois (the ancient Alesia), to Mont-Beuvray (the ancient Bibracte), and to Solutré. Dr. Marcel Baudouin, 21 rue Linné, Paris, is the secretary.

PETITIONS in support of the Metric Weights and Measures Bill, which is down for second reading on March 22, are being signed by many public bodies and institutions throughout the country. Among the petitions already received by the Decimal Association for presentation to the House of Commons is one signed by the headmaster and the whole teaching staff of Eton College.

THE model of the Channel Tunnel which was on view at Caxton Hall, Westminster, during last week was well patronised, and the voting of those who have inspected it has resulted in a large majority in favour of the scheme. The model is well made in sections, which show clearly the positions of the proposed tunnels in the chalk and the direction of the strata. An interesting point is the very slight variation of level which occurs at this part of the Channel bed.

THE death is announced of Prof. A. Y. Tsvetkoff, of the Moscow Petroffsky Forestry Institute. Soon after finishing his studies at the St. Petersburg University he obtained the degree of Master of Mathematics by a dissertation on surfaces subject to change without rupture or bend of their component parts. In 1864 he was commissioned by the Department of Agriculture abroad, and on his return he became extraordinary professor of the Moscow Institute of Forestry and Agriculture. In 1873 he became professor of mathematics at the Lycée. He read lectures also on physics and meteorology, and his auditorium was always crowded. In 1885 he retired owing to illness. He was most generous in helping poor students and others, and only after his death was it found that he had given away several thousand roubles in this way.

IN the House of Commons on March 7 the President of the Board of Agriculture was asked whether, in view of the loss now sustained by fruit growers, it is the intention of the Government at an early date to propose legislation which will enable insect and other pests which infect fruit to be dealt with effectually; and if it is intended to propose legislation, whether the Government will use every endeavour to bring it into force by May, in view of the fact that the disease will during that month begin to spread from the affected gooseberry plantations. In reply to the question, it was stated that the President of the Board of Agriculture hopes very shortly to be in a position to introduce legislation to confer on the Board and on local authorities further powers to deal with insect and other destructive pests.

AMONG the lecture arrangements at the Royal Institution after Easter we notice the following:—Prof. G. H. Bryan, two lectures on wings and aeroplanes; Prof. W. Stirling, three lectures on stimulation, luminous and chemical; Prof. G. H. F. Nuttall, two lectures on malaria, sleeping sickness, tick fever and allied diseases; Prof. H. A. Miers, two lectures on the birth and affinities of crystals; Mr. H. F. Newall, two lectures on spectroscopic phenomena in stars (1) chemistry, (2) motion; Sir James Dewar, three lectures on chemical progress—work of Mendeléeff and Moissan; Prof. S. P. Thompson, three lectures on studies in magnetism (the Tyndall lectures); Prof. W. C. McIntosh, two lectures on scientific work in the sea fisheries; and Sir Wm. H. White, two lectures on the contest between guns and armour. The Friday evening meetings will be resumed on April 12, when a discourse will be given by Prof. A. H. Church on conservation of historic buildings and frescoes; succeeding discourses will probably be given by Prof. C. S. Sherrington, Sir James Crichton-Browne, Prof. G. Chrystal, Prof. J. A. Fleming, Mr. A. H. Savage Landor, Sir James Dewar, and others.

A REUTER telegram from Rome on March 4, published in the *Times*, supplies information as to the programme of the Italian Government in the matter of the excavations at Herculaneum and other archæological schemes in Italy. It has been decided that the work shall be undertaken by the Italian Government, and the archæologists in charge of the Herculaneum excavations will probably be Profs. Dall'Osso and Pellegrini, of the University of Naples, Prof. Gabrici, of the Naples Museum, and Profs. Savignoni and Mariani. The Minister of Instruction, Prof. Rava, is making antiquities his special care, and has obtained the funds necessary to carry out an extensive programme. The yearly sum to be expended for antiquities and fine arts has been raised to nearly a quarter of a million pounds, and the appropriation for excavations has been doubled. The Minister has ordered the beginning on a large scale within a year of excavations at Ostia, the port of ancient Rome; excavations at Pæstum to find the remains of the great edifices of which Greek and Roman historians have spoken; he has obtained permission to expropriate all the houses surrounding the baths of Diocletian, and is spending 20,000*l.* to free those grand remains; and finally he has obtained 240,000*l.* for the construction of the proposed archæological promenade, which is to be finished within three years. It will start from the Roman Forum, and will pass by the Colosseum, going so far as the Baths of Caracalla on one side and the Baths of Titus and Trajan on the other.

SIR W. H. PERKIN, F.R.S., presided at the annual dinner of the Society of Dyers and Colourists on March 8. Prof. Meldola, F.R.S., proposed the toast of "The Society," and said the dinner was fittingly held on the 100th anniversary of the introduction of coal gas as an illuminant in the streets of London. The society was, therefore, doubly pleased to welcome as its president the founder of the coal-tar colour industry. The introduction of the scientific spirit into this industry is largely due to the work of Sir W. Perkin. The society is doing a great work in the particular industry represented by it, especially in bringing together representatives of the industry and of science bearing upon the industry. Good work which the society is developing is, said Prof. Meldola, the system of giving prizes for the solution of technical problems. It is a departure which can only be commended, and it is to be hoped it will be imitated by many other technical societies. The president, in reply, referred to the great advances made in other countries in the coal-tar industry during recent years, and urged manufacturers in this country, in order to maintain their supremacy in this industry, to employ in their works the services of the best scientific men. Sir W. Perkin declared that the time for energetic research is while business is prosperous. If that is done there is very little probability of decline. In commemoration of the connection of Sir W. Perkin with the society the council has decided to found a Perkin medal, which will be conferred for inventions of striking scientific and industrial merit connected with the tinctorial industry.

THE Commercial Motor Vehicle and Motor Boat Exhibition, which was opened last week at Olympia by the Lord Mayor, is likely to prove a great success, as every kind of commercial interest is well catered for. The exhibits shown include various new forms of motor 'buses, lorries, chars-à-bancs, a motor police ambulance for London, numerous forms of trade vans, and a motor horse-box. Not the least interesting of the exhibits from an Imperial point of view is the motor van which is shortly to tour the country showing Canadian products. Tyres of all descriptions, and non-slip bands and devices, occupy the gallery, and various new oils for motor lubrication are also much in evidence. Some well-finished motor boats are shown, the largest being a launch about 40 feet in length, made and fitted for the use of the Plymouth Port medical officer. A notable feature in this section is the increase in the number of boats which are propelled without the use of petrol, the paraffin engine being largely installed instead, thus obliterating one of the greatest objections to the motor boat, *i.e.* the danger of the petrol exploding. The boats are in some cases fitted with a seat for the driver similar to that in a car, and are provided with a brake. From a business point of view the exhibition should prove of great value, and is also of great interest as showing the progress made recently in heavy motor traction.

A MEETING was held on March 7 to aid the work of the National League for Physical Education and Improvement at Londonderry House. The aims of the league are to stimulate public interest in the physical improvement of the people, to coordinate and extend the work of existing agencies, to make known the legal powers already possessed by public authorities, and to promote fresh legislation where necessary. Lord Londonderry presided, and in his opening remarks said there are few persons who are studying the condition of the people of this country who do not recognise the importance of hygiene and physical education. In dealing with the question of the teaching of hygiene in the schools, he said that medical inspection

of the children should be periodically carried out, children should not be worried by over-inspection, and discretion should be exercised. As to the instruction of the children in the rules of health, care should be taken to use language which the child understands. Sir Lauder Brunton, in the course of an address, said that, in spite of all the charitable organisations and benevolent institutions in the country, infants are dying in millions, children are starved by thousands, they become weak, they are growing up burdens to themselves and useless to others, and instead of being a strength to the country they weaken it. The great weakness, misery, and crime in this country can only be attacked successfully by means of cooperation. The National League is endeavouring to effect the cooperation which is so much needed by bringing together all the individuals and corporations who are interested in the welfare of the coming generation.

A DISCUSSION on the best types of cases (combining economy with suitability) for exhibition purposes occupies a large portion of the February number of the *Museums Journal*. An article illustrated by an excellent photograph is also devoted to the new wing recently added to the Liverpool Museum.

IT appears from a paper by Dr. D. Woolacott in vol. ii., part vi., of the Proceedings of the University of Durham Philosophical Society that a raised beach in the Cleadon Hills has been unusually well exposed during the last two years. The beach is 100 feet above sea-level, but caverns and a sea-cliff indicate that the most recent depression of the country was as much as 150 feet.

THE combined January and February numbers of the *Irish Naturalist* are devoted to an account of the natural history and geology of Lambay Island, county Dublin, now in the occupation of the Hon. Cecil Baring, under whose auspices the investigation has been undertaken, and who has himself contributed notes on the seals and other mammals. A number of naturalists have contributed to the work, which has resulted in the discovery of five new species of invertebrates, and has likewise added several forms to the British fauna and a much larger number to the fauna of Ireland.

WE have been favoured with a copy of a paper from the *Jenaischen Zeitschrift* (vol. xxxix.), by Prof. Hubrecht, on the origin of annelids and chordates and the systematic position of the Ctenophora and Plathelminthes. As the "trophocœle" and "hæmocœle" theories are discussed at length, especially from the point of view of Prof. Lang, it is scarcely necessary to mention that the paper is of an extremely abstruse nature. Much importance is attached to the view that the Ctenophora are pelagic worms rather than cœlenterates, and that the Plathelminthes are likewise an aberrant type.

To the fourth part of vol. xxxvi. of Gegenbaur's *Morphologisches Jahrbuch*, Auguste Arnbäck-Christie-Linde contributes the first portion of a paper on the shrew-mice (Soricida) and their relationship to other mammals. This section of the paper is devoted to the anatomical part of the subject. It is mentioned that a lateral gland occurs in the males of the common shrew-mouse (Sorex) and water-shrew (Crossopus). Although the occurrence of such glands in the musk-shrews (Crocidura), generally in both sexes, is well known, no reference is made to their presence in the British species in such text-books as we have been able to consult.

REFERENCE in these columns was recently made to Prof. Baldwin Spencer's description of emeu bones from King Island, Bass Strait. To the January issue of the *Emu* Colonel Legge contributes notes on the extinct emeus of both that island and Tasmania. The author recalls having seen a pair of Tasmanian emeus in his boyhood, and states that they were slightly smaller than the mainland species. As this bird also lays a larger egg, it is regarded as distinct, although it does not appear to have received a scientific name. Colonel Legge withdraws, in a postscript, a name he proposed in the text for the King Island bird, owing to it having been already christened by Prof. Spencer.

"PARENTAL Care among Fresh-water Fishes" is the title of a very interesting article by Mr. Theodore Gill published in the Smithsonian Report for 1905 (art. No. 1688). Despite Aristotle's account of the care displayed by the Macedonian glanis in the preparation of a breeding-site, it was long an axiom among naturalists that fishes displayed no parental care for their eggs and offspring. How erroneous was this idea is sufficiently exemplified by the present account, although it deals only with species inhabiting fresh waters. Representatives of a very large number of groups exhibit some degree of parental care, although this may be limited to clearing a space to receive the spawn. The highest development in this respect occurs in the sticklebacks, in which the kidneys and their adjuncts are specially modified to yield a thread employed in the construction of the nest.

IN the shell-gallery of the Natural History Museum have been placed full-sized *papier maché* models of two giant cephalopods, an Architeuthis and an Octopus or Polypus. Being suspended from the roof, they show to great advantage, and convey a good idea of the huge size attained by certain members of the class, although much larger forms are known. The giant squid, or Architeuthis, measures 40 feet in total length, although 30 feet of this are accounted for by the pair of attenuated tentacular arms, the length of the body being only 10 feet. An additional interest attaches to this cephalopod on account of its constituting a large portion of the food of the cachalot. The models were obtained from Ward's Natural Science Establishment, Rochester, U.S.A. Another important addition to the collection is formed by two caribou, shot and presented by Mr. F. C. Selous, one representing the Yukon and the other the Newfoundland race. The former has antlers measuring just above 58 inches along the curve.

THE report of the Botanical Club of Canada for 1905–6, prepared by the secretary, Dr. A. H. Mackay, has been received. It contains, as usual, a summary of the phenochrons or observations on the flowering of plants and other natural phenomena recorded from several hundred schools throughout Nova Scotia, and a table of general Canadian phenological observations. Dr. Mackay has also published a handy bibliography of Canadian botany for the year 1905.

IN the *Lyttelton Times* (December 19, 1906) Dr. L. Cockayne pays a tribute to the work of the late Mr. Robert Brown, of Christchurch, New Zealand. By profession a shoemaker, he was at the same time an enthusiastic naturalist, keenly interested in the fauna and flora of the country. He devoted his energies primarily to the collection and identification of the New Zealand mosses, and contributed numerous papers during the last fourteen years that will be found in the Transactions of the New Zealand Institute.

An insidious disease of the cocoa-nut palm, known as "bud rot," has been recognised for a considerable time, but the primary cause was not determined. The view is now held that decay is due to bacteria developing in the slimy coating found on the young protected organs. Although certainly existent in the East Indies, there was no record of its occurrence in Ceylon until last year a case was brought to the notice of the Government mycologist Mr T. Petch. The disease and its treatment are noted in vol. iii., No. 15 of the Circulars and Agricultural Journal of the Royal Botanic Gardens, Ceylon. In No. 17 of the same series Mr Petch describes the root disease of the Para rubber tree caused by the bracket fungus, *Fomes semicostatus*.

In the course of an article in vol. i., No. 10 of the *Philippine Journal of Science*, on the active constituents of certain medicinal plants, Mr R. F. Bacon refers to the substances used by the Filipinos for stupefying or poisoning fish. The fibre of *Entada scandens*, the bark of *Ganophyllum obliquum* and the fruit of *Croton Tiglium* are commonly employed for the purpose. The two former contain saponin, the latter a poison allied to ricin, but it is not considered dangerous to eat fish poisoned by these substances. On the other hand, there is risk attending the consumption of fish poisoned with the fruits of *Anamirta cocculus* on account of the picrotoxin contained. The fruits of *Derris polyantha* and *Diospyros canomoi* are also used.

The Local Government Board has just issued a report on the micrococcus of epidemic cerebro-spinal meningitis (spotted fever), a disease which recently appeared in Glasgow, Belfast, Liverpool, and other places in the British Isles. The report is compiled by Dr M. H. Gordon, and contains full details of the characters of the microorganism and its recognition.

The *Journal of Hygiene* for January (vii., No. 1, just issued) contains a number of interesting and important papers. Dr Castellani describes certain cases of tropical fever associated with apparently new species of bacilli, Messrs Dudgeon and Dunkley discuss the *M. neoformans*, found in cancer by Doyen, Prof. Hewlett and Mr Barton outline the results of a chemical, microscopical and bacteriological examination of twenty-six samples of London milk, and Dr Arkwright describes the *M. catarrhalis* met with in nasal catarrh, and its differentiation. Fleet-Surgeon Bassett-Smith, R.N., contributes an important paper on the treatment of Mediterranean fever by means of vaccines. Although a few cases did well, on the whole the results were disappointing.

We have received the first number of the "Annals of Tropical Medicine and Parasitology," edited by Prof. Ronald Ross, F.R.S., and issued by the Liverpool School of Tropical Medicine. It is intended to take the place of the separate memoirs on tropical medicine which have hitherto been issued by the school, and is to be issued at the subscription price of 10s. 6d. per volume of probably not less than four numbers. The present number, of 161 pages, contains an elaborate memoir by Messrs Newstead, Dutton, and Todd, on insects and other arthropods collected in the Congo Free State, illustrated with six plates; descriptions of two new species of African ticks, by Prof. Neumann, and of parasites in the Liverpool School Museum, by Prof. Looss; a paper on the presence of *S. duttoni* in the ova of the tick, *Ornithodoros moubata*, by Captain Carter, I.M.S., and a note on the therapeutics of trypanosomiasis, by Messrs. Moore, Nierenstein, and Todd. The number is excellently printed and illustrated, and the general "get-up" all that can be desired. It bids fair to be one of the most important journals on tropical medicine in its scientific aspects.

In the *Naturwissenschaftliche Wochenschrift* (vol. vi., No. 8) Prof. H. Potonié gives an interesting historical summary of the various theories that have been propounded to explain the genesis of coal.

A paper contributed by Mr W. R. Thomas to the Institution of Mining and Metallurgy, and published in the Bulletin (No. 29) of the institution, strikingly illustrates the manner in which modern mining appliances and methods are now being adopted in Cornwall. It describes the electrically-driven centrifugal pumping plant at the Tywarnhaile mine. Special interest is attached to the installation from the fact that Dowson gas is used to run the electric plant. The results obtained have proved eminently successful.

Advance statistics, subject to correction, issued by the Home Office, show that the British output of coal in 1906 was 251,050,809 tons, or 6.33 per cent. more than in 1905. The number of persons employed at the coal mines in 1906 was 882,345. The mineral production also included 2,971,173 tons of fireclay, 8,209,880 tons of ironstone, 2,546,113 tons of oil-shale, 1,824,415 tons of iron ore, 230,558 tons of rock salt, 151,915 tons of salt from brine, and 126,699 tons of slate. The number of persons employed at mines under the Metalliferous Mines Regulation Acts was 29,969.

In a paper read before the Society of Arts, published in the Journal of the society of March 8, Prof. W. Boyd Dawkins gives a summary of the results obtained in the investigation of the south-eastern coalfield. The paper contains a map of the coalfield between Dover and Canterbury, and sections of the strata in the borings at Dover, Penshurst, Ellinge, Brabourne, Waldershare, and Fredville. At present, the seams proved are at Dover, thirteen seams with an aggregate thickness of 22½ feet; at Waldershare four seams 10 feet 3 inches thick, and at Fredville, three seams 7 feet thick. At Dover the coalfield is about 1000 feet below Ordnance datum. At Ropersole the Coal-measures were struck at a depth of 1180 feet, and at Ellinge at 1815 feet. Prof. Boyd Dawkins takes an optimistic view of the future of the coalfield, which he regards as an important national asset and a striking instance of the value of scientific research to the nation.

Very high temperatures are required in tempering the modern special tool-steels, and care has to be taken that contact with carbon or air is avoided lest the composition of the steel should be altered. A novel type of electric tempering furnace designed by Körting Brothers is described in *Engineering* of March 1. The steel is placed in a fused salt, which must have a high melting point and should not evaporate to any great extent at high temperatures. With barium chloride a temperature of 1300° C. can be maintained in such a furnace. The furnace forms a square box built up of iron, asbestos, and fire-bricks, leaving in its interior a cubical crucible chamber. This space is filled with the salt, and two plates of iron attached to opposite walls serve as electrodes for the alternating currents, supplied by an oil transformer. When the salt is fused, the object is lowered into the molten mass and the temperature controlled by means of a pyrometer and rheostats. The tools may be pre-

heated up to red glow before being placed in the furnace Primary currents of 50 or 100 periods and 200 volts are used. When keeping the furnace at its maximum temperature of 1300° C. for ten hours a day, about 2 lb. of barium chloride have to be replenished every day The furnace lining is said to last about a year, the iron electrodes do not last so long Barium chloride seems so far to be the best material for the extreme temperatures For lower temperatures mixtures of barium chloride and potassium chloride are used The crust of fused salt which adheres to the steel peels off at once when the steel is dropped into the cooling liquid Local superheating is not to be feared in this kind of furnace and the application of fused salts is attracting much attention

An interesting discussion on the advantages and disadvantages of heating buildings with gas stoves of various types, which was held at the meeting of the Royal Sanitary Institute on December 12 of last year is printed in the March number of the Journal of the institute Dr Rideal in opening the discussion considered that as soot, carbon monoxide, and hydrogen sulphide are never present in the products of the combustion of coal gas in modern gas-stoves and as the proportion of oxygen in the air of a room is little changed when the heating is effected by a flueless gas stove the use of flueless stoves was in several cases an advantage especially when the economy of the heating effect was considered The amount of carbon dioxide produced was not sufficient to be deleterious and instead of causing defective ventilation flueless stoves especially those of a condensing type seemed actually to remedy it Several speakers took part in the discussion many of them dissenting from the views expressed by Dr Rideal In particular the passage of sulphur acids into the air when a flueless stove is used appears to present difficulties

MESSRS JOHN J GRIFFIN AND SONS LTD yesterday entertained a number of visitors at their new premises in Kingsway New physical and other apparatus were exhibited and there were demonstrations of the properties of vessels made of silica glass of the oil pigment process velox printing among modern processes in photography the wireless transmission of signals the musical arc, and other physical phenomena This opportunity of seeing instruments and processes in operation is likely to be appreciated by teachers and others and Messrs Griffin and Sons Ltd will probably be repaid for their enterprise

OUR ASTRONOMICAL COLUMN

DISCOVERY OF A COMET (1907a).—A telegram from the Kiel Centralstelle announces the discovery of a new comet by Prof Giacobini at the Nice Observatory The object was of the eleventh magnitude and its position at March 9d 10h 10.9m (M.T. Nice) was

R.A =7h 4m 31.4s dec =18° 21′ 17″ S

The daily motion is westward at the rate of 47′ and northward at the rate of 57′ per day The above position lies in the constellation Canis Major, about 20′ E and 1½° S of Sirius

SOLAR RESEARCH AT MEUDON.—In No 5 (1907) of the *Comptes rendus*, MM Deslandres and d'Azambuja describe, and give some of the preliminary results of the solar researches carried out at Meudon with several forms of spectrographs, during the year 1906 One of the principal difficulties encountered by M Deslandres in his previous experiments has been to obtain a satisfactory slit so narrow that the finer dark lines of the spectrum might be completely isolated and this difficulty was, to a great extent overcome during the recent research by drawing a very fine clear line on the surface of a piece of chemically silvered optical glass By having a clear space above and below the slit the solar spectrum was simultaneously photographed on each plate, thereby enabling the parallelism of the slit and the line and the exactitude of the setting on the line to be tested for each exposure

Photographs taken on the centres of the fine iron lines at λ 4045 and λ 4385 are found to differ considerably from those taken on the degraded edges of the lines for whilst the latter show simply the bright facular areas the former show a net work of bright inequalities of very different form the photograph with the setting on the centre of the line is supposed to represent the upper layers of the iron vapours The differences between the images obtained with the K_1 and K_2 lines are not so marked as was expected although many of the bright areas obtained with the latter are not to be found on the K_2 images No relation between the K_1 images and the dark calcium flocculi of Prof Hale's photographs could be established nor could the similarity of the former with the dark areas produced by photographs on the dark hydrogen lines be recognised

THE MARKINGS AND ROTATION PERIOD OF VENUS.—Mr Denning in continuing his series of articles on the planets in the March number (No 381) of the *Observatory* discusses the contradictory results which have been derived from observations of Venus concerning the existence of permanent markings on the planet's surface and the time it takes the planet to perform one rotation on its axis He points out that whilst Mr Lowell records that he has seen the markings when their contours have "had the look of a steel engraving" numerous other very careful observers have failed to distinguish anything which might be recognised as permanent Similarly a large number of observers have arrived at the conclusion that the rotation period is about 23h–24h whilst others including Schiaparelli have concluded that it is about equal to the period of the planet's revolution in its orbit The spectroscopic results are similarly in opposition

Summing up the results of the discussion Mr Denning concludes that after the earnest application of observers during three centuries the problems of the configurations and of the axial rotation remain unsolved the difficulties having as yet proved insuperable

THE ELECTRICAL INFLUENCE OF THE SUN.—No 8 vol vii (February 23) of the *Revue Scientifique* contains an interesting discussion by Dr A Nodon of the electrical influence of the sun on the earth

After giving a historical account of the subject, the author proceeds to describe the experimental results obtained by M Brunhes and by himself from which follows the deduction that the sun produces at the earth's surface a positive electrical induction of variable magnitude The amount of this induction is far greater than that attributable to the actino-electric action of the luminous radiations whilst the interposition of clouds before the sun arrests the induction effect Other possible causes are discussed and it is shown that independently of these there still remains an effective induction directly due to the sun's charge alone

In a second part of the discussion published in No 9 of the same journal Dr Nodon considers the effect of the solar influence on the planets on comets and on the earth in particular and in conclusion he urges the fundamental importance of the study of solar physics on the grounds that a large number of meteorological phenomena appear to be directly connected with the solar changes

RECENTLY DISCOVERED ASTEROIDS.—The provisional elements of the orbits of twenty-five recently discovered asteroids are published in No 4156 (February 21) of the *Astronomische Nachrichten* by Herr J Bauschinger of the Astron Rechen-Institut Berlin These asteroids were discovered between August 1905 and April 1906 and their designatory numbers range from 570 to 598

SURVEY OF SCOTTISH LAKES

DURING the past three or four years the bathymetrical survey of 554 of the fresh-water lochs of Scotland has been completed under the direction of Sir John Murray and Mr Laurence Pullar This practically means that all the Scottish fresh-water lochs have now been surveyed, except some small ones on which no boats could be found A large staff has been employed during the course of the work—about forty voluntary and paid assistants, in addition to a great many boatmen and other workmen Up to the present time, the charts of 180 lochs, with descriptions, have been published in the *Geographical Journal*, and arrangements have now been made for the publication in the same journal during the present year of the descriptions and charts of the thirty-three lochs in the Ness basin This will complete the publication of the observations made in the more important lochs The results obtained in the case of the remaining 340 lochs will be published, as a special volume, by the Royal Geographical Society in about eighteen months from this date, the charts being at present in the course of printing by Mr. J G Bartholomew

Besides the purely bathymetrical aspect of the survey, papers have been published by Prof Chrystal on seiches, by Mr E M Wedderburn on the temperature of Loch Ness, by Mr E R Watson on ionisation of air in vessels immersed in deep water, by Dr Wesenberg Lund on a comparative study of Scottish and Danish lakes, by Prof Bachmann on phytoplankton of Scottish and Swiss lakes, by Mr G West on aquatic plants, by Mr James Murray on fresh-water animals by Drs Peach and Horne on the geological surroundings of the lochs, and other papers [1]

The last published paper [2] treats of the lochs within the basin of the Lochy the relative positions of which are shown in the little index map of the district (Fig 1) The total area of the basin exceeds 400 square miles, the diameter from east to west exceeding forty miles, and from north to south exceeding twenty miles. Of the ten lochs within the basin, five exceed three miles in length and four exceed five miles in length, while Loch Lochy is nearly ten miles, and Loch Arkaig twelve miles, in length; five of the lochs exceed 100 feet in depth, and three exceed 300 feet in depth, while Loch Lochy exceeds 500 feet in depth, five of the lochs cover a superficial area in each case exceeding a square mile, and four exceeding two square miles, while Loch Arkaig and Loch Lochy each cover an area of about six square miles The two largest lochs (Arkaig and Lochy) drain into the River Lochy, while the remaining lochs within the basin (Pattack, East and West na h-Earba, Laggan, Ossian, Ghuilbinn, Treig, and an Dubh Lochan) drain into the River Spean, which joins the River Lochy shortly after its exit from Loch Lochy, the little Loch nan Gabhar and Lochan Lùnn dà-Bhrà drain by independent streams into Loch Linnhe. In these twelve lochs, which cover an area of about twenty square miles, nearly 2600 soundings were taken, or an average of 214 soundings per loch, and 129 soundings per square mile of surface, the aggregate volume of water contained in the lochs is about 85,855 millions of cubic feet, or more than one-half of a cubic mile, and the area draining into them is more than 270 square miles, or fourteen times the area of the lochs.

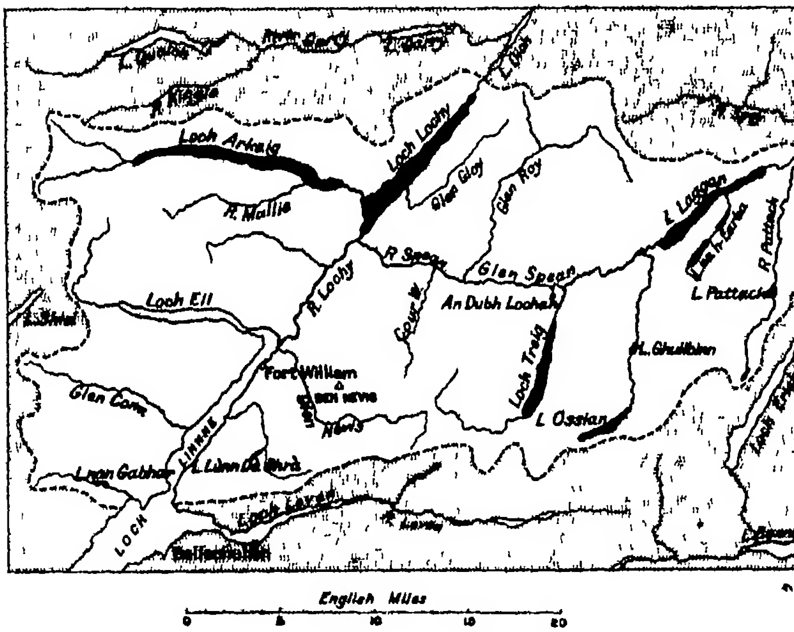


Fig 1—Index Map of the Lochy District

Loch Lochy (see Fig 2), the southernmost of the chain of lochs occupying the Great Glen utilised in forming the Caledonian Canal, is a straight loch, having the form of a narrow triangle with the apex at the north-east end, whence it widens gradually southward to Bunarkaig, where the maximum breadth of a mile and a quarter is found, the average breadth of the whole loch being three-fifths of a mile The superficial area is nearly 3800 acres, and the volume of water about 37,726 millions of cubic feet, the maximum depth being 531 feet and the mean depth 229 feet All the contour lines are continuous, the 100-feet contour enclosing an area little less than the total length of the loch, while the areas enclosed by the 200-feet 300-feet, and 400-feet contours are respectively 6½, 4½, and 3 miles in length The 500-feet contour encloses a very small area, one-third by one-eighth of a mile, just about the middle of the loch

Loch Arkaig (see Fig 3), a long, narrow, curved loch, trending nearly east and west, lying about a mile to the west of Loch Lochy, is of somewhat irregular outline, broadest in the middle parts, where the loch is nearly a mile wide, and tapering towards each end, the mean breadth being half a mile The superficial area is about 4000 acres, and the volume of water about 26,573 millions of cubic feet, the maximum depth being 359 feet and the mean depth 153 feet The basin is nearly simple, the slight irregularities being doubtless correlated with the curving outline. The 100-feet contour is continuous but the 200-feet contour is broken into two basins, and the 300-feet contour into three basins The largest 300-feet area, just about the middle of the loch, is two miles in length, and includes the maximum depth of 359 feet [1]

Loch Treig occupies a deep, narrow valley trending north and south among very high mountains in the region of Lochaber, the West Highland Railway running along the east side It is more than five miles in length, with a maximum breadth of three-quarters of a

[1] See Trans. Roy Soc Edin, vol xli pp 367, 599, 677, and 823, vol. xlv., p. 361, Proc. Roy Soc Edin, vol xxv, pp 1, 401, 593, 609, 637, 967, *Geogr Journ*, vol xxiv, p 429

[2] "Bathymetrical Survey of the Fresh water Lochs of Scotland" Under the direction of Sir John Murray, K C B, F R S, and Laurence Pullar Part xii., The Lochs of the Lochy Basin (*Geogr Journ*, vol xxviii, pp 592-615; with 8 plates of maps)

[1] It is odd that surveys were apparently made of Lochs Arkaig, Lochy, and Ness about eighteen years ago by a German military officer named Sandler, who lived for some months in the district. The results of these surveys have never been published, but a copy of that of Loch Arkaig was obtained from Mr Honeyman, factor to Cameron of Lochiel, which corresponded very closely with the results of the Lake Survey

mile, and a mean breadth of half a mile covering an area of 1540 acres, and containing 13,907 million cubic feet of water, the maximum depth is 436 feet, and the mean

Photo] Fig. 2—Loch Lochy, from the southern end [James Chumley

depth 207 feet The loch forms a narrow triangle, broadest towards the south and tapering towards the outflow the steep slope of the hills being continued under water The basin is simple, all the contours approximately following the shore-line, but the line of greatest depth is nearer the western shore The 400-feet area is about two miles in length, the two ends approaching very close to the west side, where the steepest slopes occur The valley is so narrow relatively to the depth of the loch that, in the central parts, the steep slopes reach far towards the middle and leave comparatively little level bottom but towards the south end, where the loch is broader and not quite so deep, there is a greater extent of nearly flat bottom It is interesting to note that seiches were first observed by the staff of the Lake Survey in Loch Treig

Loch Ossian lies at an elevation of about 1270 feet above the sea to the north of Rannoch Moor, trending north-east and south-west with its long axis slightly curved, and of nearly uniform breadth throughout It is 3¼ miles long, and nearly half a mile in greatest breadth the mean breadth being one third of a mile The superficial area is nearly 660 acres, and the volume of water about 1224 million cubic feet the maximum depth 132 feet, and the mean depth 43 feet The lake-floor is very uneven, both the transverse and longitudinal sections being undulate

Loch Laggan situated between the Highland and West Highland Railways, the coach road from Kingussie to Tulloch passing along the northern shore, trends north-east and south-west, and is of the usual elongate narrow form of Scottish lochs, narrowest in the central parts and somewhat expanded towards each end where deeper water occurs, the outline is very irregular, and the bottom correspondingly irregular with a number of larger and smaller islands in the narrower parts It is more than seven miles in length two-thirds of a mile in maximum breadth, the mean breadth being nearly half a mile, and the superficial area about 1900 acres The maximum depth is 174 feet, the mean depth 68 feet, and the volume of water about 5600 million cubic feet The shallower contour lines are continuous, and follow approximately the outline of the shore, but all the deeper contours are much broken up There are four 75 feet areas and six 100 feet areas, the largest and deepest approaching the west end

Lochan na h-Earba is the name applied to two distinct lochs (now differing by nearly 10 feet in level though they may once have formed a single loch) lying in a valley running nearly parallel to and about 1 mile to the south of, that occupied by Loch Laggan The *west loch* is the larger and deeper of the two, nearly two miles long by one third of a mile in greatest breadth, covering an area of about 203 acres and containing 408 million cubic feet of water, with a maximum depth of 81 feet and a mean depth of 35½ feet The basin is simple, the contour lines being continuous, but narrowing more decidedly than the outline from the centre to each end, the slopes being much steeper towards the centre of the loch The *east loch* is about half a mile distant from the west loch, the stream conveying the overflow from the west loch winding through the boggy flat between them It is 1¼ miles long by a quarter of a mile in greatest breadth, covering an area of about 140 acres, and containing 101 million cubic feet of water, with a maximum depth of 69 feet and a mean depth of 31 feet The deep water is all towards the upper end the lower half being very shallow

Besides the larger lochs thus briefly summarised details are given in the paper of Loch Pattack the highest loch surveyed in the basin with a maximum depth of 58 feet and a mean depth of 14 feet, of Loch Ghuilbinn with a maximum depth of 49 feet and a mean depth of 13 feet, of an Dubh Lochan, a very small but relatively deep loch near Loch Treig

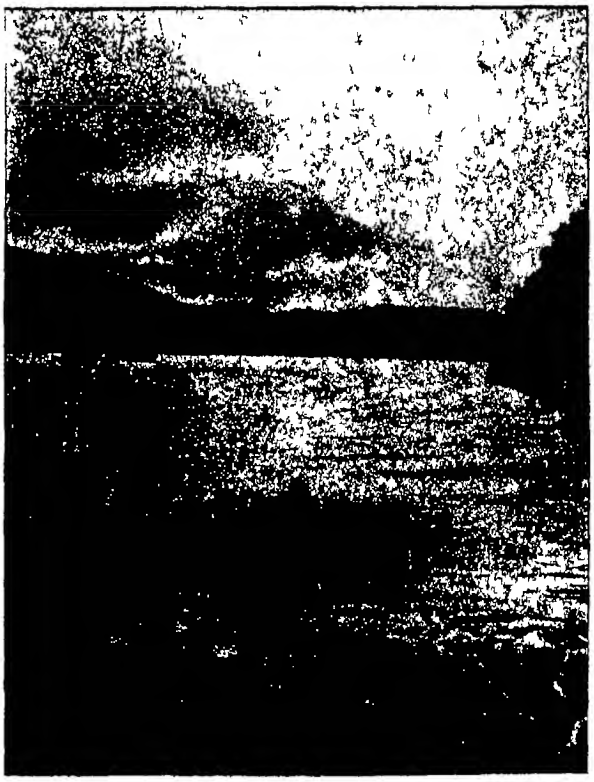

Photo James Chumley

Fig 3—Loch Arkaig, from the east end

with a maximum depth of 40 feet and a mean depth of 15½ feet, of Lochan Lunn dà Bhra with a maximum depth of 25 feet and a mean depth of 8¾ feet, and

of Loch nan Gabhar, a little weedy hollow only 5 feet deep, which is evidently being rapidly silted up. An interesting account is also given of the Red Lochan at Tulloch, a small pond lying in an extensive morainic terrace near the north end of Loch Treig, called in Gaelic by a name signifying "brown eye." It is only about 30 yards in longest diameter and 5 feet deep in the centre, fed only by rains and, though it has no outflow except by percolation through the gravel, its surface is maintained almost constantly at the same level. The water is always turbid and varies in colour from dull green to brown or red. When examined in May 1902, the water was brown, the collection with the coarse net was pale yellow, while that taken by the fine net was decidedly red; there were only two abundant organisms, the larva of an insect (Corethra) known as the "phantom larva," and a reddish-coloured rotifer, *Anuraea valga*, to which the colour of the water was evidently due, for none of the other organisms were abundant enough to be held responsible for the colour of the water. On placing the collections in formalin a blood-red sediment was deposited, which was found to consist chiefly of *Anuraea valga* and myriads of its red eggs. Examined subsequently at different seasons the changes of colour were doubtless correlated with the predominance of one or other organism. None of the other ponds in close proximity shared the turbidity and reddish-brown colour of the Red Lochan, the peculiarity being probably due to its being more closely shut in, the surrounding rim of gravel being 14 feet or more above the pond, and there is besides a fringe of birch trees. The water is stagnant, which favours the growth of certain organisms, particularly *Anuraea valga*. It is said that wildfowl never settle on the pond, and that the common frog cannot live in it. The following legend was related to Sir John Murray concerning this Red Lochan:—"Many centuries ago there lived in these parts a noted hunter named Donnuil. In return for some services rendered to the witch of Ben a Vreich, she offered to deprive the deer of the sense of sight or of smell so far as he was personally concerned. He chose to have the deer deprived of the sense of smell, 'for,' said he, 'I can easily cheat their eye.' The witch however told him that in the stomach of the last stag he would kill there would be found a ball of worsted thread. As time passed Donnuil became ill, and, while weak in bed, his daughter told him a fine stag was caught by the horns in some bushes near the house. He asked for his cross-bow, and although in bed he shot the stag through his bedroom window. Later on his daughter brought him a ball of worsted which had been found in the stomach of the stag. He knew his end was near; indeed, he died the same evening. On the following morning the Red Lochan had appeared at the place where the stag was killed."

The paper concludes with some interesting notes on the biology of the lochs by Mr. James Murray, who found that the plankton of Loch Lochy offered a remarkable contrast to that of Loch Ness, though the conditions seemed so similar, the quantity in Loch Lochy being many times greater and the species more numerous; but the special feature was the quantity and variety of the phytoplankton. In Lochan Lunn dà-Bhrà the Diaptomus was so deep red that when the nets were drawn from the water they seemed to contain blood; the same peculiarity was observed in An Dubh Lochan, but in a lesser degree.

The paper is illustrated by coloured maps showing the bathymetry and orography, and there are several woodcuts in the text, some of which are reproduced in this notice.

THE STRUCTURE OF METALS.[1]

THE lecturer said that his purpose was to give some account of researches in which he had been engaged for a good many years, dealing with the manner in which metals were built up and the manner in which their structures allowed them to yield when they were compelled to change their shape by being overstrained. A piece of metal was not a homogeneous single thing; it was a collocation of grains or granules, which built it up just as granules of ice built up a glacier. The grains of metal were irregular in shape and unequal in size. Their existence was revealed by polishing and etching the surface of the metal and examining it under the microscope, when the grains could readily be distinguished by differences of texture, and the boundaries between them could be clearly traced. Investigation showed that each grain was, in fact, a separate crystal, and the irregular boundaries were due to casual inequalities in the rates at which the various crystals had grown during their formation, which might occur when the metal was solidifying from a fluid state, or when it passed in the solid state through certain temperatures at which re-crystallisation took place. Each grain might be regarded as composed of an immense number of molecular brickbats grouped in perfectly regular tactical formation, but the direction in which these brickbats were piled was different in different grains; hence on being etched the polished surface showed differences in texture and in behaviour as to reflecting light. Microscopic photographs illustrating these features in iron and other metals were exhibited.

When the metal was strained beyond the elastic limit, and thereby compelled to change its form, the change of form took place by slips occurring between the layers of molecular brickbats in the individual granules. The discovery of these slips had been made by the lecturer in conjunction with Mr. Walter Rosenhain, by noticing certain lines to appear on the polished surface of a piece when subjected to severe strain. These lines, which they called slip lines, looked like minute crevasses, but were really steps caused by the slipping of one layer on its neighbours, just as cards might slip in a pack. In any one crystal grain there were at least three sets of independent parallel planes in which such slips could take place, and these allowed the grain to undergo complete alteration of form as a result of the straining. Microscopic photographs were exhibited showing three systems of slip lines on the surface, corresponding to slips in three directions throughout the substance of the grain. The true nature of these slip lines was made apparent by means of obliquely incident light, which showed them as little steps in the surface. An interesting direct confirmation of this had been afforded by recent experiments of Mr. Rosenhain, in which cross-sections of the stepped surface had been obtained.

Dr. Ewing next explained by aid of models, a theory which he had recently advanced as to the structure of the crystal granule itself. This theory might be regarded as an extension of the views he put forward fifteen years ago to explain the phenomena of magnetic induction by the mutual actions of polarised magnetic molecules. Cohesion in the crystalline structure might similarly be regarded as due to the mutual forces between polarised molecules, the polarity of which determined the regular tactical formation in which they grouped themselves to form the crystal. For this purpose he conceived of each molecule as possessing polarity along each of three rectangular axes, in other words, as having six poles exercising forces of attraction on the opposed poles of neighbouring molecules.

The lecturer proceeded by aid of the model, to demonstrate the process of crystal-building with these polarised molecules for brickbats. He showed how, under certain conditions, a group of dissenting molecules might be formed within the crystal grain possessing a certain degree of stability, though not in complete harmony with the molecules around them. Evidence for the existence of such groups was furnished by the microscope in the examination of iron and other metals. The process of straining was next considered, and it was shown that the conception of polarised molecules was in agreement with what was known of the actual behaviour of metals during, first, the elastic stage of straining, and, second, the stage where much greater yielding took place and permanent set was produced. The molecular theory explained how energy was dissipated in the process of straining, and also how elastic "fatigue" resulted. After any severe strain the piece was a long time in recovering its full amount of elastic quality, but the recovery could be accelerated by heating it. These phenomena were accounted for by

[1] Abstract of "Wilde" Lecture, delivered by Dr. J. A. Ewing, F.R.S., before the Manchester Literary and Philosophical Society on February 18.

the setting up of dissenting groups, as a result of straining, which resolved themselves after a time into the normal configuration. It further explained the fatigue of strength which was found to occur when a metal was subjected to repeated reversals of stress, a matter of great practical importance in the design of machines and engineering structures. The manner in which a piece broke, for example, after repeated bendings to and fro was discussed by aid of the molecular model. It was shown that the effects of slip are felt for some distance on either side of the plane of slip, a fatigued condition of the metal being established. This is especially the case when slip is many times repeated, backwards and forwards, and a condition is ultimately arrived at in which the cohesive bonds are broken and a crack results.

In conclusion, Dr. Ewing briefly referred to the relation between the molecular structure of the crystal grain, to which strength and elasticity were to be ascribed, and the finer structure which accounted in magnetic metals for the phenomena of magnetism. He had formerly shown that in the process of magnetisation in iron there was a turning round of a molecular axis possessing magnetic polarity. It was when the magnetically polar axes of all the molecules were turned round so as to face one way that the iron became "saturated." The polarity he was now concerned with was different in kind. It was not magnetic, and it existed in three directions, whereas the magnetic polarity with which the process of magnetisation was concerned was uniaxial. Moreover, the three-directional polarity concerned in crystal building did not suffer rotation when a magnetising force was applied. We had accordingly to think of the molecule as possessing polar axes which were non-magnetic and remained fixed under the control of forces of the same kind exerted by the poles of neighbouring molecules, and at the same time as possessing an inner structure characterised by uniaxial magnetic polarity, which was capable of rotation under the influence of an applied magnetising force while the non-magnetic polar axes remained fixed.

FORTHCOMING BOOKS OF SCIENCE.

MESSRS. BAILLIÈRE, TINDALL AND COX direct attention to:—"Practical Agricultural Chemistry," by F. Robertson; "Meat Inspection," by Dr. W. Robertson; "Blood Stains (a Medico-legal Book)," by Major Sutherland; "Trypanosomata and the Trypanosomiases," by A. Laveran and F. Mesnil, translated and edited by Dr. D. Nabarro; and a new edition of "The Röntgen Rays in Medical Work," by Dr. D. Walsh, with section on apparatus and methods by Dr. L. Jones.

Messrs. A. and C. Black announce:—"Notes upon the Island of Dominica (British West Indies)," by S. Grieve, illustrated; "Rudolf Eucken's Philosophy of Life," by W. R. B. Gibson; "The Sense of Touch in Mammals and Birds, with Special Reference to the Papillary Ridges," by Dr. W. Kidd; "How to Fish," by W. E. Hodgson; "Man, his Manners and Customs," by L. W. Lyde; and "Descriptive Geography of the British Isles," by F. D. Herbertson.

Messrs. William Blackwood and Sons promise:—"In the Footsteps of Marco Polo, being the Account of a Journey Overland from Simla to Pekin," by Major C. D. Bruce; "The Sovereignty of the Sea: an Historical Account of the Claims to the Exclusive Dominion of the British Seas and of the Evolution of the Territorial Waters, with Special Reference to the Rights of Fishing," by Dr. T. W. Fulton; "In Malay Forests," by G. Maxwell; and "Forest Entomology," by A. T. Gillanders.

In Messrs. Cassell and Co.'s list we find:—"Greenhouses and Conservatories, Constructing and Heating"; "Steel, its Varieties, Properties, and Manufacture"; "Domestic Hot Water Supply"; "Iron, its Sources, Properties, and Manufacture"; "Photographic Studios and Dark Rooms"; "Window Blinds"; "Tinplate Work"; "Rustic Carpentry"; "Pumps and Rams, their Action and Construction"; "Domestic Jobbing"; and "Zinc Working."

Messrs. Chatto and Windus give notice of:—"A History of Sumer and Akkad, being an Account of the Primitive Inhabitants of Babylonia, with Maps and Illustrations after all the Principal Monuments of the Period in the British Museum and Elsewhere, and a Special Binding Design after a Monument of the Period," by L. W. King; and "The Paradise or Garden of the Holy Fathers, being Histories of the Anchorites, Recluses, Cœnobites, Monks, and Ascetic Fathers of the Deserts of Egypt between A.D. CCL and A.D. CCCC circiter, compiled by Athanasius, Archbishop of Alexandria; Palladius, Bishop of Helenopolis; Saint Jerome, and others, now translated out of the Syriac, with Notes and Introduction," by Dr. E. A. W. Budge.

Messrs. Archibald Constable and Co., Ltd., announce:—"European Animals, their Geological History and Geographical Distribution," by Dr. R. S. Scharff; "Natives of Northern India," by W. Crooke; "Universal Dictionary of Mechanical Drawing," by G. H. Follows; "Railroad Curve Tables for the Field Engineer," by R. S. Henderson; "Cranes," by A. Böttcher, translated from the German, enlarged, and edited with a complete description of English and American practice by A. Tolhausen; "Searchlights," by F. Nerz, translated from the German by C. Rodgers; "Agglutinants and Adhesives," by H. C. Standage; "Irrigation, its Principles and Practice as a Branch of Engineering," by Sir H. Brown; "Design of Irrigation Works," by W. Bligh; "Experimental and Theoretical Applications of Thermodynamics to Chemistry," by Prof. W. Nernst; "The Elastic Arch, with Reference to the Reinforced Concrete Arch," by B. R. Leffler; "Machine Design," by C. H. Benjamin; "A Text-book of Hydraulics, including an Outline of the Theory of Turbines," by L. M. Hoskins; "Fuel, Water, and Gas Analysis," by J. B. Kershaw; "Gas, Oil, and Solid Fuel," by Prof. V. B. Lewes; "Gold and Precious Metals," by Dr. T. K. Rose; "Electrometallurgy," by J. B. C. Kershaw; "Electrical Distribution of Power," by J. H. Davis; "Gas Light and Heating," by W. H. Y. Webber; "Coal," by J. Tonge; "Iron and Steel," by J. H. Stansbie; "The Manufacture of Paper," by R. W. Sindall; "India-rubber and Gutta-percha," by H. L. Terry; "Wood Pulp and its Applications," by C. F. Cross, E. J. Bevan, and R. W. Sindall; "Steam Engines," by J. T. Rossiter; "Glass," by W. Rosenhain; "Electric Lamps," by M. Solomon; "Steam Locomotives," by V. Pendred; "Patents, Trade Marks, and Designs," by K. R. Swan; and "Photography," by A. Watkins.

Messrs. J. M. Dent and Co.'s list includes:—"Nature-study," by Prof. J. R. A. Davis; "Trigonometry," by C. Hawkins; "Fly-fishing," by Sir E. Grey, illustrated; "Our Gardens," by the late Dean Hole and G. S. Elgood; and "Farming," by W. M. Tod, illustrated.

Messrs. Duckworth and Co. announce:—"The Interpretation of Nature in Earlier Greek Art," by E. Löwy, translated and illustrated; and a new edition of "A Text-book of Plant Diseases," by G. Massee.

In Messrs. Everett and Co.'s list appears:—"Charts of the Diseases of the Horse, with Explanatory Notes and Prescriptions," by C. Gresswell.

Mr. Gustav Fischer (Jena) will publish:—"Die Bakteriologie des Auges," by Prof. Axenfeld, illustrated; "Das Dysenterietoxin," by Dr. R. Doerr, illustrated; "Geologische und Palaeontologische Abhandlungen," edited by E. Koken, Band viii., Heft iii., illustrated; "Die Grosshirnrinde des Menschen in ihren Massen und in ihrem Fasergehalt," by Dr. T. Kaes, i Teil, text, 2 Teil, illustrations; "Praktikum der Bakteriologie und Protozoologie," by Drs. K. Kisskalt and M. Hartmann; "Jahresbericht der Literatur über physische Anthropologie im Jahre 1905," by Dr. E. Fischer, edited by Dr. G. Schwalbe; "Normentafeln zur Entwickelungsgeschichte der Wirbeltiere," edited by Prof. F. Keibel, Siebentes Heft: "Normentafel zur Entwickelungsgeschichte des Koboldmaki (Tarsius Spectrum) und des Plumplori (Nycticebus Tardigradus)," by Prof. A. A. W. Hubrecht and F. Keibel, illustrated; "Progressus rei Botanicae: Fortschritte der Botanik; Progrès de la Botanique; Progress of Botany," edited for the International Association of Botanists by Dr. J. P. Lotsy, Erster Band, Zweites Heft; "Verhandlungen der deutschen pathologischen Gesellschaft," Zehnte Tagung gehalten in Stuttgart vom September 17-21, 1906,

Jahrgang 1906, illustrated, "Wissenschaftliche Ergebnisse der deutschen Tiefsee-Expedition auf dem Dampfer *Valdivia* 1898–1899," Funfzehnter Band, 1 Lieferung, die Tiefsee Fische by Prof A Brauer, Systematischer Teil, illustrated "Zoologische Forschungsreisen in Australien und dem Malayischen Archipel," by Prof R Semon Dritter Band, Monotremen und Marsupialier II, 2 Teil 3 Lieferung, illustrated, and "Klinisches Jahrbuch," Sechzehnter Band, Zweites Heft illustrated

Mr H Frowde promises —"Australasia," by J D Rogers, being the sixth volume of the "Historical Geography of the British Colonies", "The Dillenian Herbaria an Account of the Dillenian Collections in the Herbarium of the University, together with a Biographical Sketch of Dillenius, Selections from his Correspondence, Notes &c" by G C Druce, edited, with an introduction, by Prof S H Vines, F R S, "Ancient Khotan" detailed Report of Archaeological Exploration in Chinese Turkestan, carried out and described under the Orders of H M Indian Government by M A Stein, 2 vols, and "Surgical Instruments in Ancient Times," by J S Milne

Messrs Greening and Co, Ltd, promise —"Practical Fruit Culture" by J Whitehead, "Practical Glass Culture" by J Cheal, and "Home Pets," by H Compton

The list of Messrs Charles Griffin and Co, Ltd, includes —"The Design and Construction of Ships" by Prof J H Biles 2 vols illustrated, "The Problem of Flight" by H Chatley, illustrated "Practical Calculations for Engineers," by C E Larard and H A Golding, illustrated "Shaft Sinking in Difficult Cases" by J Riemer translated from the German by J W Brough, illustrated "The Analysis of Materials used in the Leather Industry," by S R Trotman, illustrated "Soil Bacteria" by Dr J Clark, illustrated, "General Foundry Practice a Practical Handbook for Iron, Steel and Brass Founders, Metallurgists and Students of Metallurgy" by A McWilliam and P Longmuir, illustrated "Physico-chemical Tables for the Use of Analysts, Physicists Chemical Manufacturers, and Scientific Chemists," vol i, "Chemical Engineering Physical Chemistry" vol ii "Chemical Physics, Pure and Analytical Chemistry," by J Castell-Evans 2 vols, "Medical Ethics" by Dr R Saundby, and new editions of "A Manual of Dyeing, for the Use of Practical Dyers Manufacturers, Students and all Interested in the Art of Dyeing" by Dr E Knecht, C Rawson and Dr R Loewenthal 2 vols "Principles and Practice of Brewing for the Use of Students and Practical Men," by W J Sykes, revised by A R Ling illustrated "The Work of the Digestive Glands," by Prof Pavlov, translated into English by Dr W H Thompson, illustrated

Mr W Heinemann's list contains —"A Handbook of Metabolism" by Prof C von Noorden, English translation edited by Dr I W Hall 3 vols, "The Nutrition of Man" by Prof R H Chittenden, illustrated, "The World's History a Survey of Man's Record," edited by Dr R F Helmolt vol v, "Eastern Europe" "Eclipse and O'Kelly" by T A Cook, illustrated and "Wild Flowers of the British Isles," written by H I Adams illustrated

Messrs Hodder and Stoughton promise —"Brain and Personality or the Physical Relations of the Brain to the Mind" by Dr W H Thomson, illustrated, and "The Book of the Open Air," by F Thomas, twelve monthly parts, illustrated

The list of Messrs Hutchinson and Co contains —"Extinct Birds" by the Hon W Rothschild, illustrated "The World's Peoples," by Dr A H Keane, illustrated, "In Wildest Africa," by C G Schillings, translated by F Whyte, 2 vols, illustrated, "Nearest the Pole," by Commander R E Peary illustrated, and "Maori and Polynesian," by J M Brown

Messrs P S King and Son direct attention to —"The Infant the Parent, and the State a Social Study and Review," by H L Heath and "Central Poor-law Conference, 1907, Report of the Proceedings of the Central Poor-law Conference held on February 19 and 20 at the Guildhall London", "Poor-law Conferences, 1906–7, Annual Volume containing the Reports of the Proceedings of the Central and District Conferences held from May, 1906, to February, 1907, with the Report of the Central Committee"

Mr John Lane's list contains —"Ornithological and other Oddities," by F Finn, illustrated, "Forms of Paralysis," by Dr J S Collier; "The Post-mortem Handbook," by Dr C R Box, "Minor Operations," by E M Corner, "Book of Rock and Water Gardens," by C Thonger, "The Book of the Chrysanthemum," by P S Follwell, "The Book of Fruit Bottling," by E Bradley and M Crooke, and a new edition of "The Tree Book," by M R Jarvis

Messrs Crosby Lockwood and Son give notice of —"Modern American Lathe Practice," by O E Perrigo, illustrated, "Graphical Handbook for Reinforced Concrete Design," by J Hawkesworth, with an appendix containing the requirements of the Building Code of New York City *in regard to reinforced concrete, illustrated*, "The Construction of Dynamos (Alternating and Direct Current), a Text-book for Students, Engineer-constructors, and Electricians-in-charge," by T Sewell, illustrated, "A Handbook of Wireless Telegraphy its Theory and Practice, for the Use of Electrical Engineers, Students, and Operators," by Dr J Erskine-Murray, illustrated, "The Twentieth Century Book of Recipes, Formulas, and Processes containing nearly 10,000 Selected Scientific, Chemical Technical, and Household Recipes, Formulas and Processes, for Use in the Laboratory, the Office the Workshop and the Home," edited by G D Hiscox, illustrated, and new editions of "Mechanical Engineer's Pocket-book of Tables, Formulæ, Rules, and Data, a Handy Book of Reference for Daily Use in Engineering Practice," by the late D K Clark, revised by H H P Powles, and "A Handybook for Brewers, being a Practical Guide to the Art of Brewing and of Malting," by H F Wright, illustrated

Messrs Longmans and Co's announcements include —"Design in Nature, illustrated by Spiral and other Arrangements in the Inorganic and Organic Kingdoms as exemplified in Matter, Force, Life Growth Rhythms &c, especially in Crystals Plants, and Animals," by Dr J B Pettigrew, F R S, illustrated, "Nature Round the House, a Simple Natural History for Small Students," by P Wilson, illustrated, "Hydraulics," by Prof S Dunkerley, 2 vols "Electro physiology of Plants," by Prof J C Bose, illustrated, "Investigation on the Theory of the Photographic Process," by Drs S E Sheppard and C E K Mees, "The Teaching of Mathematics in the Elementary and the Secondary School," by Dr J W A Young, and "Systematic Researches in Thermo-chemistry Numerical and Theoretical Results," by J Thomsen, translated by K A Burke

In the list of Messrs Macmillan and Co, Ltd, are to be found —"Inflammation," by Prof J G Adami, F R S, "Mining Tables" by Hatch and Valentine, "Geometry Papers," by R Deakin, "Steam and Other Engines," by J Duncan, and new editions of "Modern Views of Electricity," by Sir Oliver Lodge, F R S, "A Hunter's Wanderings in Africa," by F C Selous; and "Woolwich Mathematical Papers," edited by E J Brooksmith

Mr Elkin Mathews directs attention to —"The Days of a Year a Naturalist's notes from January 1 to December 31" "the Harvest of a Quiet Eye."

Mr Murray's list includes —"Life and Adventures of Captain Cook, R N, the Great Circumnavigator of the World," by A Kitson, illustrated, "Cretan Excavations and their Bearing on Early History," by Prof R M Burrows "Heredity," by Prof J A Thomson, "Recent Development in Biological Science," by W B Hardy F R S, "A Primer of Psychology," by L Brackenbury, "Notes on the Teaching of Elementary Chemistry, with a Sequence of Experiments on Air and Combustion," by J B Russell (teacher's edition)

Messrs A Owen and Co announce —"The Moon in Modern Astronomy," by P Fauth.

Messrs George Philip and Son, Ltd., will publish —"A New Physical Geography for Intermediate and Secondary Schools" by E O Williams, and "Builders of the Body," by E Miles

Sir Isaac Pitman and Sons, Ltd, give notice of new editions of "Great Astronomers," "In Starry Realms,"

and "In the High Heavens," three works by Sir R S Ball, F.R.S.; "Astronomy for Everybody," by Prof S Newcomb, with an introduction by Sir R S Ball, "By Land and Sky, the Record of a Balloonist," by Rev J. M Bacon, "Minute Marvels of Nature," by J. J Ward, and "Peeps into Nature's Ways," by J J Ward.

Messrs G P. Putnam's Sons' list contains —"The Family, an Ethnographical and Historical Outline, with Descriptive Notes, planned as a Text-book for the Use of College Lecturers and Directors of Home-reading Clubs," by Dr E L. Parsons, "Hunting Big Game with Gun and with Kodak how Wild Animals Look and Live in their Haunts, from Personal Experiences in the United States, Dominion of Canada, and Old Mexico," by W S Thomas, illustrated; "On the Great American Plateau, Wanderings among Canyons and Buttes in the Land of the Cliff Dweller, and the Indian of To-day," by T M Prudden, illustrated, "Diagnosis of Organic Nervous Diseases," by Dr C A. Herter, revised by Dr L P Clark, illustrated, "The Sporting Rifle," by W Winans illustrated; "Scientific Sanction for the Use of Alcohol," by Dr. J Starke; "The Muscles of the Eye," by Dr L. Howe, 2 vols; "Philosophical Problems in the Light of Vital Organisation," by E Montgomery, and a new edition of "A Manual of Prescription Writing, with a Full Explanation of the Methods of Correctly Writing Prescriptions, and Rules for avoiding Incompatibilities and for Combining Medicines," by Dr M D Mann

Messrs Alston Rivers, Ltd, promise —"Ten Years of Locomotive Progress, with an Introduction upon Modern Railway Policy and Practice," by G Montagu

Messrs. Scott, Greenwood and Son give notice of — 'Industrial Alcohol, a Practical Manual on the Production and Use of Alcohol for Industrial Purposes," by J G McIntosh, "Modern Flax, Hemp, and Jute Spinning," by H. R Carter, "Celluloid, the Raw Material, Manufacture, and Uses," by Dr F Böckmann, "Paper Testing," by Dr H P Stevens, "The Preparation of Paper for Special Purposes," by L E Andés, "Pottery Decorating," by R. Hainbach, "Grammar of Textile Design," by H. Nisbet, and new editions of "The Practical Compounding of Oils, Tallow, and Grease for Lubrication", "A Manual of Agricultural Chemistry," by H Ingle, "Cotton Spinning, for Honours Students," by T Thornley, "Workshop Wrinkles," by W N Brown, "Recipes for Flint-glass Making"

Messrs Smith, Elder and Co give notice of —"Animal Life," by Dr F. W Gamble, illustrated, and "The South Polar Times," reproduced in facsimile, the periodical brought out by the officers of the National Antarctic Expedition on board the *Discovery* during the Antarctic winters of 1902 and 1903, illustrated

Messrs. Swan Sonnenschein and Co, Ltd, direct attention to —"How to Study Geology," by E Evans, and a new edition of "Life by the Sea-shore, an Introduction to Natural History," by Dr M Newbigin

Messrs E and F N. Spon, Ltd, announce —"The Smith and Forgeman's Handbook of Practical Smithing and Forging," by T Moore, "English Weights, and their Equivalents in Kilogrammes," by F W A Logan, "The Stoker's Catechism," by W J Connor "A Treatise on the Grouping of Electric Cells," by W F Dunton "Experimenting with Induction Coils," by H S Norrie, "Mechanical Draft, a Practical Handbook for Engineers and Draftsmen," by J H Kenealy, "Types and Details of Bridge Construction," by F W Skinner, part ii, "Plate Girders", "Designs for Small Dynamos and Motors," by C P Poole, and new editions of "A Treatise on Surveying," compiled by R E Middleton, O Chadwick, and J Du T Bogle, part ii and "The Management of Electrical Machinery," by F B Crocker and Dr S. S. Wheeler

Mr Edward Stanford announces —Vol i of "Australasia" in Stanford's "Compendium of Geography and Travel," by Prof J. W Gregory, F R S illustrated

Mr Elliot Stock promises —"Natural History of the British Butterflies," by J. W Tutt, vol i, illustrated

The University Tutorial Press, Ltd, will issue — "Plant Biology," by Dr F. Cavers, and a new edition of "Physiography," by Drs R W Stewart and W Briggs.

Mr Fisher Unwin's list contains —"Woodlanders and Field Folk," by J Watson, "The Birds of Middlesex," by J. E. Harting, illustrated, "The Psychology and Training of the Horse," by Count E M Cesaresco, "The Principles and Practice of X-Ray Diagnosis and Therapy," by Dr J Rudis-Jicinsky, with the collaboration of C H Treadwell and Dr J Hoffman, illustrated, and "The Horse, a Pictorial Guide to its Anatomy," 110 drawings (reproduced by photolithography) by H Dittrich, with explanatory notes by Profs Ellenberger and Baum

Messrs Watts and Co announce —"An Essay Outline of Evolution," by D Hird

The following are Messrs Whittaker and Co.'s announcements —"Modern Practice of Coal Mining" by D Burns and G L Kerr, "Armature Construction," by H M Hobart and A G Ellis, "Electricity in Mining," by P R Allen, "Electric Lamps and Photometry," by L Gaster, "Motor-car Construction," by T Gray, "The Care of Motor Cars," by T Gray, and "An Advanced Text-book of Steam, Gas, and Oil Engines," by J W Hayward

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD —The master and fellows of University College have established a "Radcliffe prize" for the encouragement of research in medical science, it will be awarded every second year alternately with the Rolleston prize Its value is 50*l*, and it is open to all graduates who have not exceeded twelve years from the date of passing the last examination for the degree of Bachelor of Arts and are not Radcliffe fellows at the date of application Candidates must send in their memoirs to the secretary to the boards of faculties on or before June 1

CAMBRIDGE —The Master of Trinity Hall has consented to act, and will be formally appointed to act as deputy for the Vice-Chancellor for the period from March 22 to April 24, when the Vice-Chancellor will be absent in America representing the University at the opening of the Carnegie Institute

The subject selected for the Adams prize in 1908 is "The Radiation from Electric Systems or Ions in accelerated Motion and the Mechanical Reactions on their Motion which arise from it" The prize is open to the competition of all persons who have at any time been admitted to a degree in this University The essays must be sent in to the Vice-Chancellor on or before December 16 1908, privately The successful candidate will receive about 225*l*

A university lecturer in pathology will shortly be appointed The stipend is 100*l* per annum Candidates are requested to send their names and testimonials to the Vice Chancellor on or before April 19

The next combined examination for sixty-six entrance scholarships and various exhibitions at Pembroke, Gonville and Caius, King's Jesus, Christ's, St John's, and Emmanuel Colleges will be held on December 3 and following days Mathematics and natural sciences will be the subjects of examination at all the above-mentioned colleges A candidate for a scholarship or exhibition at any of the seven colleges must not be more than nineteen years of age on October 1, 1907 Forms of application for admission to the examination at the respective colleges, and further information respecting the scholarships may be obtained as follows —Pembroke College, Mr W S Hadley, Gonville and Caius College the Master, King's College, Mr W H Macaulay, Jesus College Mr A Gray, Christ's College, Rev J W Cartmell, St John's College, Dr J. R Tanner, Emmanuel College, the Master

DR H T BARNES, assistant professor of physics in McGill University, Montreal, has been appointed professor of experimental physics in succession to Prof E Rutherford, F R S

THE sixth annual students' soirée of the Sir John Cass Technical Institute will be held on Saturday, March 16. The programme includes special demonstrations and short addresses on scientific subjects in the laboratories and workshops of the institute.

ON April 23 the University of Glasgow will confer the honorary degree of Doctor of Laws upon Sir George Watt, author of the "Dictionary of the Economic Products of India"; Prof. E. Boutroux, Paris; Prof. J. Norman Collie, F.R.S.; Prof. U. Dini, Pisa; Prof. J. H. Poincaré, Paris; Prof. John G. McKendrick, F.R.S.; and Principal D. Macalister.

THE estimated expenditure on education, science, and art for the year ending March 31, 1908, is given in the Civil Service Estimates, recently issued, as 17,495,237*l*, which is a net increase of 310,955*l* upon the grants made in the fiscal year just ending. The following extracts show how some of the estimates compare with the grants made in the preceding year:—

	1507 8	Compared with 1906-7 Increase	Decrease
	£	£	
Board of Education	13,593,646	254,046	—
British Museum	171,041	1,043	—
Scientific Investigation, &c.	54,479	—	3,171
Universities and Colleges, Great Britain, and Intermediate Education, Wales	201,400	1,000	—
Public Education (Scotland)	2,022,554	50,426	—
Public Education (Ireland)	1,408,360	15,137	—
Queen's Colleges (Ireland)	4,700	—	161

The apparent decrease in the estimate under scientific investigation is explained by the fact that in 1906-7 the grant to the National Physical Laboratory for new buildings and equipment was 10,000*l*, instead of the 5000*l* to be granted to the laboratory in 1907-8.

THE executive committee has submitted to the trustees of the Carnegie trust for the universities of Scotland its sixth annual report, which is concerned with the administration of the trust during the year 1906. Under the scheme of allocation for five years of an annual grant of 40,000*l* among the four Scottish universities, which became operative on January 1, 1903, sums of 37,280*l* were claimed and paid during 1906. The grants for library purposes and for provisional assistance in teaching amounted for the year to 6400*l*. For buildings and permanent equipment the grants for 1906 reached 26,189*l*. Payments towards teaching endowments to the extent of 4700*l* were made, and there is under this head an unexpended balance of 25,132*l*. Under the scheme of endowment of post-graduate study and research appointments were made to seventeen fellowships and to thirty-seven scholarships. Grants of varying amounts were in addition paid to forty applicants. The total expenditure under this scheme was 6,903*l* during 1906, and it is estimated that during 1907 8094*l* will be spent. The expenditure upon the Royal College of Physicians laboratory during the year was, so far as the trust is concerned, 314*l*—this amount being independent of the capital invested in taking over the property of the laboratory buildings. The report directs attention to modifications in the scheme of payment of class fees adopted last year by the committee, the first limited payment of fees of further classes to those beneficiaries who had passed their graduation examinations up to date, and the second modification limited payment of fees of advanced classes to those who had proved their ability to profit by such classes. A striking diminution in the number of beneficiaries and in expenditure upon class fees followed the adoption of these modifications. The report is provided with extensive appendices which supply detailed information concerning the numerous activities of the trust.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 13, 1906.—"The Velocity of the Negative Ions in Flames." By Ernest Gold. Communicated by Prof. H. A. Wilson, F.R.S.

The experiments described in this paper may be regarded as a continuation of the investigations of the properties of ions in flames carried out by Prof. H. A. Wilson in this country and by Marx and Moreau on the Continent.

The determinations of the velocity of the negative ions previously made had led to the conclusion that the ions were of the nature of corpuscles loaded with electrically neutral molecules. The present series of experiments shows that this is not the case, but that the ions are probably free electrons.

The first part of the paper gives an account of experiments made with platinum disc electrodes immersed in a flame obtained by burning the gas from a large Bunsen burner at a row of holes in a quartz tube (quartz for insulation). It is shown that the conductivity of the flame is unaffected by putting salt on the electrodes, although the current is increased from $7{\cdot}3 \times 10^{-4}$ to 261×10^{-4} ampere, a result which enables the gradient to be determined from the current.

The value of the conductivity obtained and the number of ions per c.c. deduced from experiments by Prof. Wilson and the author (*Phil. Mag.*, April, 1906) enable an approximate value to be found for the velocity of the negative ions in an electric field. The velocity so obtained, 8000 cm. per second for an intensity of one volt per cm., was of a different order from those previously obtained (1000 cm. per sec.).

The latter had been found on the assumption that for small potential differences between platinum electrodes the gradient in the flame was uniform from electrode to electrode, the very close way in which Ohm's law was followed for small applied E.M.F.'s serving as a foundation for the assumption. The measurement of the gradient for applied E.M.F.'s of the order of one volt across 5 cm. is complicated by the variations in the potential taken up by a platinum wire in the flame due to changes in the temperature and ionisation. These changes are large compared with the quantities to be measured, and ordinary methods of deducing corrections leave possible errors of the same order as the corrected quantity. To avoid this difficulty a special arrangement was adopted, in which, by using a thermocouple as explorer, the actual variations due to the applied E.M.F.'s were separated from the incidental variations in the flame. It was found in this way that the fall of potential consisted of a rapid drop at the electrodes, at the negative electrode for the free flame, and at the positive when salt was vaporised beneath the kathode, together with a uniform gradient in the body of the flame.

The results so obtained gave the gradient necessary to drive the ions of salt vapour from the kathode to the anode while they travelled upwards with the stream of gas.

If v is the upward velocity of the flame gases, h the height of the electrodes, d the distance between them, and x the distance the salt vapour extends from the kathode, the velocity k of the negative ions for unit electric field is given by $k X/d \quad x=v/h$, where X is the gradient found as above. The velocity v of the flame gases was found by photographing the images of bright particles in the flame formed by reflection at a plane mirror attached to an electrically-driven tuning-fork.

The value found for the velocity of the negative ions for a gradient of one volt per cm. was found to be 12,900 cm. per sec.

The velocity of a corpuscle of mass m and charge e in an electric field of intensity X is $Xe\lambda/mu$, where λ is the mean free path and u the mean velocity of agitation of the corpuscles. Taking for e/m, λ, u, the values 10^7, 3×10^{-4}, $2{\cdot}32\times10^7$ respectively, we get for a field of one volt per cm. a value 13,000 cm. per sec. nearly, a result in close agreement with the value for the velocity of the ions found experimentally. It appears therefore that the

negative ions in flames are free electrons, and not atoms or loaded corpuscles

Interesting results, suggesting a field for further investigation, were found for the gradient when salt was vaporised beneath both electrodes

January 24.—"On a New Iron Carbonyl and on the Action of Light and Heat on the Iron Carbonyls" By Sir James **Dewar**, F R S, and Dr H O **Jones**.

The paper contains an account of the extension of the experiments, previously described, on the action of light on the liquid iron pentacarbonyl and on the action of heat on the resulting solid compound, diferrononacarbonyl In the course of the experiments, new and interesting observations were made, and a new compound of iron and carbon monoxide discovered

The action of light on iron pentacarbonyl alone or in solution results in the formation of $Fe_2(CO)_9$ and carbon monoxide, except in two cases, (1) when the solvent is nickel carbonyl, and (2) when the temperature is above 56° C

The absence of any action due to light above 56° C has been confirmed by using tubes fitted with a small manometer, which showed no change of pressure when no solid was deposited, and showed that the deposition of solid was a delicate test for any action

At 35° C solid was deposited, and pressure developed in five minutes in sunlight

At 45° C to 50° C solid was deposited, and pressure developed in thirty minutes in sunlight

At 56° C *no* solid was deposited, and *no* pressure developed in five to twelve hours in sunlight

The velocity of the reaction was measured, and it was found to be a reaction of the "first order" The rate of decomposition was compared with the rate of the reaction between ferric chloride and oxalic acid, which was investigated by Lemoine, it was found that iron carbonyl was slightly more sensitive to light than the mixture used by Lemoine

The rate of the reverse action of carbon monoxide on the solid, which takes place in the dark was also measured, and was found to be very small at the ordinary temperature, but to have a fairly normal temperature coefficient, the velocity was approximately trebled for an increase of 10° C

Thus a reasonable explanation of the absence of any action of light above 56° C can be suggested If the direct action induced by light has a very small temperature coefficient, as the reaction investigated by Lemoine has, the reverse action being about 240 times as rapid at 56° C as at 16° C would easily prevent the accumulation of appreciable quantities of the products of the decomposition

The action of heat on diferrononacarbonyl alone has been shown to produce a decomposition represented by the equation $2Fe_2(CO)_9 = 3Fe(CO)_5 + Fe + 3CO$. When the solid was heated in the presence of hydrocarbons ether bromobenzene, or iron pentacarbonyl however, *green* solutions were obtained, iron pentacarbonyl was produced, but no gas was evolved, if alcohol, pyridine, acetone, or acetonitrile was the liquid used, *red* solutions were obtained, but no gas was evolved with nickel carbonyl as solvent, gas was evolved and iron deposited From the green solutions, under suitable conditions lustrous green crystals were deposited, these were found to be a new compound *iron tetracarbonyl*, $x\{Fe(CO)_4\}$, where x is large, probably about 20

The new compound has a molecular volume of 84 for the unit $Fe(CO)_4$ and is very stable It is not decomposed by hot concentrated hydrochloric acid, is attacked by hot concentrated sulphuric acid giving carbon monoxide and *ferrous sulphate*, and is readily decomposed by cold nitric acid

Iron tetracarbonyl dissolves in hydrocarbons, ether, iron pentacarbonyl, nickel carbonyl acetone, and acetonitrile to give green solutions which do not change on heating for a short time, and which deposit the green compound unchanged when evaporated out of contact with air in pyridine and alcohol the compound dissolves to give a green solution, which changes slowly in the cold and rapidly on heating into a red solution

The green solutions exhibit a characteristic absorption band in the yellow while the red solutions show no selective absorption

Chemical Society, February 21 —Prof R **Meldola**, F R S, president, in the chair —The constitution of hydroxyazo-compounds W B **Tuck**. Several of the hydroxyazo-compounds were examined spectrographically and it was found that the absorption spectra of the *p*-hydroxy-compounds agree closely with those of their derivatives The ethers of *o*-compounds also agree with the *p*-compounds, but the benzoyl derivatives are similar to benzoquinonebenzoylphenylhydrazone —The influence of solvents on the rotation of optically active compounds, part ix, a new general method for studying intramolecular change T S **Patterson** and A **McMillan** —Displacement of halogens by hydroxyl, i, the hydrolytic decomposition of hydrogen and sodium monochloroacetates by water and by alkali, and the influence of neutral salts on the reaction velocities G **Senter** On the basis of the results obtained, the hypothesis put forward by R J Caldwell, that the accelerating influence of neutral salts on certain catalytic actions is due to the withdrawal of water and consequent concentration of the reacting substances, was criticised It is considered that the effect in question is due to the action of the ions of the salt on H' and OH' ions —The interaction of ammonium salts and the constituents of the soil A D **Hall** and C T **Gimingham** —The reduction products of *o*- and *p*-dimethoxybenzoin J C **Irvine** and Miss A M **Moodie** —Constituents of natural indigo, part ii A G **Perkin** Numerous Java indigos have been found to contain kampferol The leaves of *Indigofera sumatrana* contain a trace of what is probably kæmpferol —The velocity of hydrolysis of aliphatic amides J C **Crocker** —The rates of reaction of formamide, acetamide, propionamide butyramide isobutyramide, valeramide, capronamide with hydrochloric acid, have been determined at from 40° to 80° The reactions are bimolecular, and the order of the relative reactivities is the same for each temperature A relation between the reactivity of the amides at constant temperature and the strength of the corresponding organic acids was indicated —The rusting of iron W R **Dunstan** In order to explain the fact that the rusting of iron can take place in the absence of carbonic acid and that only iron, oxygen, and liquid water are necessary, the working hypothesis was suggested that the formation of hydrogen peroxide is concerned in the change, rusting being prevented by those substances which are capable of decomposing the peroxide (Trans Chem Soc, 1905 lxxxvii, 1548) The results of further experiments carried out by the author show that iron rusts freely in the absence of carbonic acid, provided that iron, oxygen, and liquid water are brought together —Contributions to the chemistry of the rare earths, part ii M **Esposito**. The methods of Muthmann and Böhm and Pattinson and Clarke for the preparation of ceria have been found to give a fairly pure product Lanthana and old didymia can be separated by fractional crystallisation of the oxalates from strong nitric acid Lanthana is best obtained by fractional crystallisation of the double ammonium nitrates After one hundred and ten fractionations, lanthana praseodymia, and neodymia were obtained in a state of considerable purity —Derivatives of multivalent iodine, part iii, action of heat on iodobenzene dichloride and on the *m* and *p*-nitro- and *p*-chloro-derivatives W **Caldwell** and F A **Werner** —The organic phosphorus compound formed by yeast-juice from soluble phosphates Preliminary notice W J **Young** A lead salt of the compound was prepared from the fermentation mixture by first removing any free phosphate by magnesium nitrate, and then adding lead nitrate Analyses of two preparations, in which the carbon hydrogen lead and phosphorus were determined gave the empirical formula $C_3H_5O_6PPb$ From a solution of this the free acid can be obtained which reduces Fehling's solution, gives Mohlisch's a-naphthol reaction is slightly dextrorotatory, and can be titrated with alkalis —Experi

ments on the synthesis of the terpenes, part x, synthesis of carvestrene and its derivatives W H **Perkin**, jun, and G **Tattersall** Continuing their work on the synthesis of carvestrene, the authors have prepared *m*-cineol by the action of magnesium methyl iodide on ethyl *cyclo*-hexanone-3-carboxylic acid, and the *cis*- and *trans*- modifications of *m* menthane-1 8-diol have also been obtained

Zoological Society, February 19 —Sir Edmund G Loder, Bart, vice-president, in the chair —Remains of a bear from the superficial deposits of a cavern in the mountains of Corsica, where bears, though now extinct, were formerly numerous, at least up to the sixteenth century Dr C I Forsyth **Major** Despite the fact that no truly fossil bears were as yet known from Corsica, Dr Forsyth Major considered the Corsican bear to have been autochthonous, whilst in his opinion the recent mammals of Corsica (and Sardinia) had been, almost without exception, introduced by human agency In any case, they could not be adduced as proofs of a recent connection of those islands with either of the neighbouring continents —English domestic cats R I **Pocock**. The author urged that the surest basis for their classification and the most satisfactory clue to their descent was furnished by the two distinct patterns found in so-called tabby cats In one type the pattern consisted of narrow vertical stripes, in the other of longitudinal or obliquely longitudinal stripes which, on the sides of the body, tended to assume a spiral or subcircular arrangement characteristic of the "blotched" tabby This distinction was long ago pointed out by Blyth One or the other of these types was to be found in cats of almost all breeds, whether "Persian," "short-haired," or "Manx" There appeared to be no intermediate stages between the two The cats of the "striped" type were no doubt descended from the European wild cat and the North African wild cat, but the origin of cats exhibiting the "blotched" pattern appeared to be unknown It was to the cat of the latter kind that Linnaeus gave the name *catus*, which was therefore no longer available for the European wild cat, this cat, therefore, must take the name *sylvestris* —Report on the deaths that occurred among the mammals and birds in the society's menagerie during 1906 Dr C G **Seligmann** 356 Mammals and 283 birds were submitted to *post-mortem* examination, and the results showed that (1) tuberculosis occurring in birds in the gardens was usually due to infection by the gut (2) the hearts of rheas, cassowaries, ostriches, and some of the larger storks kept in the gardens were often extremely flabby, and death in these birds was in a large number of cases due to cardiac failure (3) new growths were rare both in mammals and in birds, but one case of carcinoma arising in the kidney, and occurring in a Chilian pintail (*Dafila spinicauda*), had been observed, as well as two instances of benign new growths occurring in birds not inmates of the gardens —A peculiarly abnormal specimen of the turbot J T **Cunningham**. The specimen was captured near Padstow, on the north coast of Cornwall It was a young fish, measuring only 4 4 cm in length and a normal specimen of slightly smaller size, taken at the same time was completely metamorphosed to the asymmetrical condition of the adult In the abnormal specimen the right side was almost entirely destitute of colour as in the normal condition but both eyes were on this white side instead of being on the left side, as in normal turbot On the left side pigment was present over the whole surface except the head and the anterior part of the base of the dorsal fin which were white. The fish was kept alive in captivity for two months and was observed to lie always with its eyes uppermost so that the upper side was white and the lower side coloured —Ideas on the origin of flight Dr Baron I **Nopcsa**. The author stated that from the mechanical point of view a patagium and a set of flight-feathers were different organs He pointed out the osteological analogies between bats and pterosaurs, on the one hand, and between birds and dinosaurs on the other He suggested that bats and pterosaurs had arisen from leaping arboreal forms, whilst birds had come from a terrestrial, cursorial stock —The azygos veins in the Mammalia F E **Beddard**

Royal Microscopical Society February 20 —Lord Avebury, F R S president, in the chair —An early criticism of the Abbe theory J W **Gordon** This was a reply to a paper by Mr Conrady with the same title, read before the society on October 17, 1906. At the conclusion of his paper Mr Gordon exhibited on the screen some photographs of the spectrum produced by the fine ruling of an Abbe diffraction plate —Some Tardigrada from the Sikkim Himalaya James **Murray**.—Some Rhizopods from the Sikkim Himalaya Dr Eugène **Penard**.—An incident in ant life Major **Sampson**. A thick living arch of travelling ants was seen by Major Sampson, now in Southern Nigeria, across a sunny road, and in the centre hundreds of pupæ being carried along in the shade thus caused This is remarkable, because the African ant, as a rule, dislikes the sun

Physical Society, February 22 —Prof J Perry, F R S, president, in the chair —Transformer indicator diagrams Prof T R **Lyle**. The term "transformer indicator diagram" has been applied by Prof Fleming to any series of periodic curves which give the forms, relative phase positions, and magnitudes of the waves of current and E M F on both the primary and secondary sides of a transformer when working Such diagrams have been obtained by many investigators in different ways, but by none of the methods hitherto used has it been possible to determine directly and independently either the wave of magnetic flux F in the core, or the wave of magnetising-current turns usually represented by the vector sum $n_1C_1+n_2C_2$ It is shown in the paper that the integral $\int(n_1C_1+n_2C_2)dF$ for one cycle is equal to the total iron loss per cycle, and the advantage of being able to determine both $n_1C_1+n_2C_2$ and F directly and accurately is apparent By means of the wave tracer designed by the author, not only can the E M F and current waves be accurately determined, but also the wave of magnetic flux pulsating in the core of the transformer, and in addition the magnetising current wave, $n_1C_1+n_2C_2$, can be obtained with the same accuracy as any of the other quantities —Ionisation of gases by α particles of radium Prof **Bragg** The present paper contains an account of further progress in the work of determining the relative amounts of ionisation produced by the α particle of RaC in different gases and vapours The view is discussed that the ionisation (i) is connected with the expenditure of energy (e) of the α particle by the expression $\delta i/\delta e = kf(v)$, where k is a constant for each gas which may be termed the specific ionisation in terms of air as unity, the determination of which for various gases has been attempted in the present paper, and $f(v)$ is a function of the velocity of the α particle only It is established that the total number of ions produced by the α particles of RaC varies with the nature of the gas, and is for most compound gases and vapours examined about one-third greater than for air The conclusion is drawn that the primary action of the α particle is a subatomic one The production of ions may be considered a secondary consequence which varies with the energy expended the speed of the particle, and the nature of the molecule ionised The stopping-power of a gas is more nearly an additive property of the atoms in the molecule than any other property except mass, and this is an effect quite apart from the proportionality of stopping-power to the square root of the atomic weight For atomic weights below 30 the stopping-power, divided by the atomic square roots, is abnormally low an effect curiously similar to the case of atomic heats There does not appear any evidence that the chance of an atom being ionised is dependent upon whether it is already ionised, that is occasionally the molecule may lose several ions

Anthropological Institute, February 26 —Dr A C Haddon, F R S vice-president, in the chair —Note on a dolmen called "La Pierre Turquaise," at Presles, France A L **Lewis**. The monument consists of a chamber, with an entrance, formed by two small stones, which originally supported a third. The roof is formed of nine stones. The axis is between twenty and twenty-five degrees south of west and north of east The total length is about 45 feet The monument appears to have been sepulchral, but rites of some kind were also probably performed at it —The ethnology of modern Egypt Dr C S **Myers**. The measurements, notes, and photographs taken in this investigation led to the conclusions (1) that, compared with the "prehistoric" people of 5000 B C, the modern

inhabitants show no sensible difference in head measurements or in the degree of scatter of individual measurements about their average, (2) that the modern Copts throughout Egypt are less negroid than the modern Moslem population, (3) that both the Copts and the Moslems in Upper Egypt are more negroid than those in Lower Egypt, (4) that from the anthropometric standpoint there is no evidence of plurality of race in modern Egypt.

Geological Society, February 27.—Sir Archibald Geikie, Sec. R.S., president, in the chair.—The Lower Ordovician succession in Scandinavia: W. G. **Fearnsides**. The paper is a stratigraphical account of the Dictyonema shales, the Ceratopyge beds, the Didymograptus shales, and the Orthoceras limestone of Sweden and southern Norway, and is based upon field-observations of Scandinavian type-localities made by the author during the summer of 1906. The beds are discussed under the following headings:—(c) Didymograptus shales and Orthoceras*kalk*, (b) Glauconite shales and Ceratopyge*kalk*, (a) Dictyonema and Bryograptus shales, which are found to be applicable to all the sections visited. This stratigraphical evidence is considered in its bearing upon the question of the definition of the boundary between the Cambrian and the Ordovician systems, and the author follows the Scandinavian authorities in considering that, so long as the Dictyonema horizon is available, the evidence of sudden faunistic change within the series discussed is too slight to warrant a palæontological separation of the systems at any other horizon. A comparison of the British Tremadoc and Arenig series with these Scandinavian rocks concludes the paper, and it is maintained that the time has now arrived for British geologists to come into line with their Continental brethren and to include the Dictyonema and the overlying Tremadoc beds as the lowest series of the Ordovician system.—The occurrence of pseudomorphous pebbles of pyrites at the Crown Reef Mine (Witwatersrand): C. B. **Horwood**. Reference is first made to the existence of calcite "pebbles" in the Main Reef, which Mr. Julius Kuntz believes to be due to the replacement of quartz by calcite. Pellets of iron-bisulphide known as "buckshot" occur at the Rietfontein "A" Mine in the Buckshot Reef: they exhibit radiate fibrous structure, and are probably of concretionary origin. At the Crown Reef Mine a few "pebbles" of pyrites, some measuring as much as an inch in length, occur in a narrow band of conglomerate at the contact of the reef with a basic dyke.

DUBLIN

Royal Dublin Society, February 19.—Prof. A. W. Conway in the chair.—Electrical seed-testing: Prof. T. **Johnson**. A demonstration was given of the method of using the apparatus devised by Dr. A. D. Waller, F.R.S., for testing for a "blaze" current in electrical seed-testing.—Series in spectra: Prof. A. W. **Conway**. A sphere of positive electricity is supposed, capable of executing radial elastic vibrations of low frequency. In any mode a negative electron could at certain periods be at rest for some time at any one of the nodal surfaces. The frequencies of the oscillations of an electron at the various nodes would be connected by an equation

$$a+bn^{-2}+Cn^{-4}$$

where n is a natural number.

PARIS

Academy of Sciences, March 4.—M. Henri Becquerel in the chair.—The heats of combustion and formation of some nitrogenous principles playing a physiological *rôle*: M. **Berthelot** and Ph. **Landrieu**. Thermochemical data for hæmatin, bilirubin, and hæmoglobin *from the horse*.—The phosphorescence of uranium salts in liquid air: Henri **Becquerel**. At the temperature of liquid air the bands observed in the spectrum at ordinary temperatures are partly resolved into lines, and the bands not resolved into lines contract and are more sharply defined. The phosphorescent spectrum is similarly modified.—The alcoholysis of castor oil: A. **Haller**. Castor oil was treated with various alcohols containing 1 per cent. of hydrochloric acid, and the esters obtained submitted to repeated fractional distillation in a vacuum. Methyl, ethyl, *n*-propyl, and isobutyl ricinoleates were obtained, the physical constants of which are given. The presence in the oil of the glycerides of stearic, ricinoleic, and dioxystearic acids was confirmed.—The purification of sewage: A. **Muntz** and E. **Lainé**. In previous work the authors have found that for intensive nitrification peat forms the best medium for the work. This result has now been applied to the purification of sewage. The filter bed consists of spongy peat, to which chalk has been added in sufficient quantity to neutralise the acidity, together with a little garden mould to supply the necessary nitrifying organisms. After passing through two small septic tanks, the sewage is filtered through the peat-bed at the rate of 1 to 1.25 cubic metres per day per square metre of surface, and analytical data are appended showing the completeness of the purification.—The obliteration of the pleural cavity in the elephant: Alfred **Giard**. A continuation of the discussion raised by Mme. Phisalix.—Remarks on the preceding paper by M. Edmond **Perrier**.—The formula of addition of spherical functions: Niels **Nielsen**.—The constitution of the atom: H. **Pellat**. Starting with the present theory of the constitution of the atom as being formed of a centre positively charged around which gravitate negatively charged electrons, the calculation is made that for sodium, zinc, iron, and copper, the only light radiations possibly emitted by the vapours should be well in the ultra-violet. As this is not in accordance with the known facts, it is pointed out that some of the fundamental assumptions of the theory must be modified.—The refraction of bodies: Jules **Amar**.—Some new modes of formation and preparation of titanium tetrachloride: Em. **Vigouroux** and G. **Arrivaut**. Commercial ferrotitanium, from which the greater part of the iron has been removed by treatment with dilute hydrochloric acid, is dried and heated in a current of chlorine. A good yield of titanium tetrachloride is thus obtained, and details are given of the method of purifying it, especially from the accompanying ferric chloride.—The synthesis of tertiary amidines: phenyl-amido-ethane-oxymethane-phenylimino phenylamine: Emm. **Pozzi-Escot**.—The constitution of hordenine: E. **Léger**.—A method of synthesis of non-substituted β-ketonic nitriles: Ch. **Moureu** and I. **Lazennec**.—A new method of estimating ammonia in waters: Albert **Buisson**. The method is based on the product of an insoluble compound by the addition of mercuric chloride and sodium carbonate.—The origin of the formation of aldehydes in cheese: MM. **Trillat** and **Sauton**. The bite in cheese has been shown to be largely due to the formation of aldehydes. In the present paper the best means of preventing aldehyde formation is studied.—The toxic power of the definite principles in *Tephrosia Vogelii*: M. **Hanriot**.—The colloidal properties of starch: J. **Fouard**.—The relations existing between the oxyhæmoglobin and the gases of the blood: MM. **Piettre** and **Vila**.—The influence of the physical nature of the walls on the increase of activity of the pancreatic secretion by calcium salts: C. **Delezenne**.—The structure of the cubical form of sodium chlorate possessing rotatory power: H. **Copaux**. The cubical crystals of sodium chlorate owe their rotatory power to the macles of a quasi-cubic orthorhombic form slightly doubly refractive.—A contribution to the anatomical study of the Raphia of Madagascar: P. **Claverie**.—The edible fishes of Lake Melah (Algeria): J. **Bounhiol**.—A new form of anidian evolution: Jan **Tur**.—The existence in the Sipunculidæ of Schizogregarians belonging to the family of the Selenidiidæ: L. **Brasil** and H. B. **Fantham**.—Reclamation of priority on the subject of a note by M. SEX AND CHARACTER

Sex and Character. By Otto Weininger. Authorised translation from the sixth German edition. Pp. xxii+356. (London: W. Heinemann, 1906.) Price 17*s.* net.

WEININGER'S interest in his problem is much more philosophical than scientific, but he finds the basis of his theory in a biological idea, and thus challenges scientific criticism. His philosophy is of the non-empirical type, and he is strongly influenced by Plato and the transcendentalism of Kant. His psychology and ethics are thus static and non-evolutionary, and he is the less likely to find any strong support from modern thinkers, for whatever in these days may be our views as to the method by which it has come about, the *fact* of organic evolution is beyond dispute, and the application of evolutionary ideas to psychology and ethics hardly less compelling.

The book is an attempt to reduce the relation of the sexes to a single principle, and Weininger brings arguments from biology, psychology, logic, and ethics to enforce his claim to have established it. He begins by predicating a permanent bisexual condition in human beings, pointing out that the sexual condition in the embryo is derived from an earlier indeterminate stage, and that there are always traces of bisexuality in the adult, *e.g.* the down on a woman's face in the position of the beard and the presence of glandular tissue connected with the nipples in man.

"The fact is that males and females are like two substances combined in different proportions, but with either element never wholly missing. We find, so to speak, neither a man nor a woman, but only the male condition and the female condition. Any individual 'A' or 'B' is never to be designated merely as a man or as a woman, but by a formula showing that it is a composite of male and female character combined in different proportions, for instance as follows:—

$$A \begin{cases} aM \\ a'W \end{cases} \quad B = \begin{cases} bW \\ b'M \end{cases}$$

always remembering that each of the factors *a*, *a'*, *b*, *b'* must be greater than 0 and less than unity."

Weininger elaborates this biological idea and carries it into the field of psychology and ethics. He seeks to explain the periodic movements for the emancipation of women by the periodic appearance of unusual numbers of women approaching the male standard (his so-called hermaphrodites), and supposes that all such movements die out because the hermaphrodite individuals who create the demand for emancipation after a certain time are no longer produced, an argument which he supports by biological analogies, but though there have been such movements in the past, they were doomed to failure, because it is only in our own epoch that the fear of rape, which is the *real* reason for the suppression and prohibitions accorded to women, has become so small a probability that it may be disregarded in view of the enormous gain to intellect and character afforded by the fullest possible freedom.

Weininger proceeds to inquire what are the essentials of the ideal maleness and the ideal femaleness which form the ends of his series, and on his way elaborates his theories of psychology and ethics. Memory he takes as the basis of logic and of ethics, for without memory there can be no perception of identity, and hence no possibility of a syllogism. The perception of identity necessitates the supposition of a transcendental ego which is out of time, for the ego must be permanent and the same at all times to be able to recognise identity when it turns up. James, however, has shown that for the purposes of psychology all that is necessary is the present thought which contains and remembers and recognises all past thoughts. The thought, then, *is* the thinker, and the transcendental ego a needless and cumbersome abstraction.

How does this male psychology apply to woman? Thus dogmatically Weininger:—Woman has no memory, and hence no perception of identity, hence she is illogical and non-moral. She is incapable of forming concepts, all her ideas are in the vague stage in which the object perceived is inseparable from the character or feeling with which it is perceived. That is to say, in general, her mentality is in a less differentiated or articulated stage than man's. Here again we might find some grounds for seeing a partial truth in our author's contentions, if he were content to say that, on the whole, this was true of the average woman as compared with the average man, all due allowance being made for education and logical training; but he goes very much farther than this. "Woman has no ego," and moreover, "I must again assert that the woman of the highest standard is immeasurably below the man of lowest standard." Here common-sense observation and all anthropological, psychological, and ethical investigations give him an emphatic negative.

Woman, then, according to Weininger, is nothing (*Nichts*), the complete antithesis of man, who is something, an ego, a microcosm (*All*), though containing within him the possibility of nothingness (*Nichts*), of chaos, of insanity, of crime. What, then, is her place in humanity? "Woman is sexuality, man is sexuality and something more." Here, then, we have the secret of woman. She is nothing but the instrument of a blind instinct to perpetuate the race, all her practical interests are in sexual congress (the courtesan type), in procreation (the mother type), in match-making. "The idea of pairing is the only conception which has positive worth for women." "The female is concerned altogether with one class of recollections, those connected with the sexual impulse and reproduction."

The women of history and of daily experience clearly cannot be fitted into Weininger's conception of them, but that, he would say, is because of their extraordinary capacity for assimilating man's ideas, his morality, his ideals of chastity, of honour, and his respect for logic. When a woman accepts man's standards too thoroughly her nature (sexuality) re-

Y

volts, and hysterical crises result The patient alternately passionately repudiates her sexual instincts and brazenly asserts them It is hard to imagine how a creature without memory or logic could perform all the mental processes involved in this assimilation and repudiation

Weininger now turns on man Woman is nothing, and therefore non-moral, not immoral, but man in his relations with her is always immoral For he always regards her as a means to an end, and not as an end in itself, in sexual congress as the instrument of pleasure and physical reproduction, in love as the instrument of self projection and mental reproduction, but woman is part of humanity, and must be regarded as an end in herself The present writer, for one, fails to comprehend how a person who has no ego and is nothing can be regarded as an end in herself!

Specious and persuasive as our author shows that he can be it is clear that he is very far from establishing his principle The book is a remarkable one for the author's years—he was only twenty-one when he wrote it remarkable in the learning and thought which he brings to bear no less than in the largeness of its conception and the breadth with which the matter is treated It is brilliantly written and contains at once profound reflections and almost laughably unfounded statements of fact It is at times stimulating and suggestive, but nevertheless often irritating, because the central idea seems rather an obsession of a brilliant but inexperienced mind than a conception to which the writer has been driven by carefully considered facts

Weininger died by his own hand in 1903, and we are told by the friend who collected his posthumous papers that he felt within him criminal tendencies, and could no longer continue the struggle between these tendencies (*Nichts*) and his intelligible ego (*All*)

I A

SOME RECENT LOGARITHMIC TABLES

Tableaux logarithmiques, A et B By Dr A Guillemin Pp 48 of explanation, with two tables 35×55 and 46×35 cm (Paris Félix Alcan, 1906) Price 4 francs complete

Clive's Mathematical Tables Pp 40 (London University Tutorial Press Ltd, 1906) Price 1s 6d

Five-figure Mathematical Tables for School and Laboratory Purposes By Dr A Du Pré Denning Pp 21 (London Longmans, Green and Co, 1906) Price 2s net

DR GUILLEMIN'S two tables possess several interesting features Taking, in the first place Table A, which is used for working to six places of decimals, this contains the *antilogarithms*, calculated to six decimal places, of all decimals of three places from 0 000 to 0 999 In a third column are given the values of log a corresponding to values of log $(1+a)$, from 0 000000 to 0 000999 When it is required to calculate logarithms to six places of decimals, the principle employed is as follows —Let N be the number the logarithm of which is required, m the nearest number in the column of antilogarithms, so that $\log m = \log N$ to three places of decimals Then if $N = m(1+a)$ we have

$$\log N = \log m + \log (1+a)$$

By subtraction we find $N-m$, which is equal to ma From the tables we can find by inspection $\log ma$ to three decimal places, and subtracting $\log m$, which is known, we have $\log a$ to three decimal places The table then gives $\log (1+a)$ to three significant figures, and these figures are the second three decimals to be written after $\log m$ in order to give $\log N$ to six places

In the second table (Table B) the values of the antilogarithms are given to nine places of decimals, and the values of $\log a$ to six places In each table the number of entries is one thousand, the logarithms going from 0 000 to 0 999 With Table B, which measures 35 cm by 46 cm, it is possible to calculate any logarithm to nine decimal places, but the work involves something more than a repetition of the process used for Table A If, for example, it is required to find log 7, there is no difficulty in obtaining the first six figures 0 845098 but the remainder to be operated on in order to find the next three figures cannot be got until we have worked the whole thing backwards and calculated the antilogarithm of 0 845098 to nine decimal places

It is not often that logarithmic calculations have to be taken to nine decimal places, but if this has to be done the present method, which is very fully explained by the author avoids the use of cumbersome books of tables and it will probably be found, with a little practice not to take much longer—perhaps not even to take so long as the interpolation methods which such books of tables would necessarily involve

The other tables under review are good examples of a number of small tables which have been issued during the last few years with the object of saving elementary students in mathematics, as well as students in physics and chemistry, from the tedious work of looking out seven-figure logarithms in the large "Chambers" It has been felt for a long time past that working with four figures is sufficient for teaching purposes, on the other hand, the student of experimental science often requires the additional accuracy obtained by an extra decimal place But though several cheap books of four-figure tables have been issued during the past few years, we had to retain "Chambers" for teaching and examining junior students until about four months ago, as none of the other books we saw contained what was necessary One contained natural sines and cosines, but not their logarithms, another contained natural and logarithmic sines, but no cosines

Junior students are very fond of using natural sines when they ought to learn to use their logarithms They invariably get inaccurate results by clumsy methods, and it would not be a bad plan to remove the tables of natural sines from the books supplied for examinations

The proper arrangement for a table of trigono-

metric logarithms is one which shows clearly the dual use of the tables for reading off the logarithmic sines of angles and the logarithmic cosines of their complements With small books of tables this is best done by using the right-hand column and top line for logarithmic sines, the left-hand column and bottom line for logarithmic cosines This is the arrangement adopted by Dr Briggs in his "Clive's Mathematical Tables" The same arrangement is followed in regard to tangents and co-tangents The tables of secants and cosecants are another desirable feature By adding the logarithm of a cosecant instead of subtracting the logarithm of a sine many compound expressions may be calculated by a single addition sum It is a pity that logarithms of reciprocals are not also given The tables are given to five places, and corrections are given in all of them where the differences are irregular The explanatory matter is very useful to students, notably the definition of significant figures

Dr Denning, in his introduction remarks that "Criticisms and suggestions for future editions will be welcomed" The first criticism which suggests itself is that a book where logarithms of numbers less than four *have necessarily* to be taken from a table of antilogarithms, and logarithms of numbers greater than four from a table of logarithms, is far too ingenious to put into the hands of a beginner The object of this arrangement is, of course, to avoid the large and irregular differences that occur with logarithms of the lower numbers and antilogarithms of the higher ones If the book is *not* meant for beginners the arrangement is good, but for teaching the use of tables the complete tables of logs and antilogs should be given and students should be taught later on when to use each The insertion of corresponding tables for obtaining logarithms of reciprocals is a good feature It seems rather curious that no one has adopted the plan of bordering a table of antilogarithms with a bottom line and right-hand column containing the arithmetical complements of the numbers in the top line and left-hand column Such an antilogarithm table would give logarithms of reciprocals very simply

The arrangement of the trigonometrical tables is not very clear There are no head- or footlines to the middle page, and while the columns look to run on from one page to the next, they do not really do so The left-hand column of the first two pages goes from 0° to 15°, and we naturally expect to find 15° to 30° on the next page, but instead of that we find 30° to 45°, the entries for 15° to 30° being on the right-hand column of the first two pages The misprint "co-functions" at the foot of p 16 does not really introduce additional confusion The book contains tables of squares and cubes for those who like to indulge in such luxuries Pages of physical and chemical constants, electric units and data, together with some of the differentiation and integration formulæ also given, are really useful, and, finally, some "simpler mechanical relationships" and statements of the binomial and Maclaurin's theorems would be of greater value to the average student if they bore the heading "Things that Ought Not to be Learnt"

These criticisms do not preclude us from stating that the tables will be very useful to such science students as have learnt to find their way about in them

GEOGRAPHY AS A LIVING SCIENCE

Beobachtung als Grundlage der Geographie By Prof Albrecht Penck Pp 63 (Berlin Gebruder Borntraeger, 1906) Price 1 60 marks

THIS little work, which is choicely printed is a record of a delightful personality It contains the parting address of Prof Penck to the students of Vienna, and his introduction to those of Berlin, now the suzerain-city of the land where he was born The first words "Liebe Freunde" ring very truly in our ears, and the title of the pamphlet recalls to those friends scenes in very many lands Especially prized by the present writer is a little photograph—a mere imperfect sketch, if you will—in which Prof Penck is seen writing up his notes in the open air, on the very edge of one of the world's great landscapes, where the scarp of the African tableland goes suddenly down towards the sea Like his distinguished botanical colleague, Prof Engler, Penck has realised the tradition of Humboldt, and has felt that the German people "darf sich in geographischer Arbeit nicht auf sein Gebiet beschranken es muss solche auf der ganzen Erde leisten" (p 60)

The striking contrast of geographical position makes it necessary to urge the claims of travel more strongly in Berlin than in Vienna The romance of Vindobona and Carnuntum, of the Germanised city facing the great "Kessel, in den sich Volkerwoge auf Volkerwoge sturzte" calls us eastward in the first few pages, and we ask ourselves What has Berlin to offer after this? In the last pages, however, we meet our answer—Germany centres in the flat land of Berlin, but Germany has spread her wings Near the North Pole lies King William Land, near the South Pole lies Emperor William II Land, and the union of the German States has allowed all Germany to look towards the sea On this medium, which no longer divides but joins the continents, we trust that ships may bear in all directions the students of Berlin, imbued as they cannot fail to be with the high and genial spirit of their master

In the Austrian section of the pamphlet, Prof Penck shows how tectonic geography has specially developed in Vienna He urges, however, that the relations between internal structure and surface-features are not always so close as has been supposed The forms associated with the higher regions of the Alps are thus due less to the recent folding of the chain than to the surface-action of the glaciers of the Ice age and of modern times (p 16) which continuously carry away, by a nibbling action, fragments from the valley-walls The author believes that the Alps were far more rounded before the advent of the Ice age, though they possessed (p 20) a much

dissected Flysch zone, and that the contrast between the surface of the young folded chain and that of the old "Rumpf" of Bohemia is in reality a development of fairly recent times The Alps, moreover (p 18), appear to have gained in height, by a vertical movement, since the formation of the interglacial lakes, and thus their present preeminence is not to be ascribed to lateral thrust alone

The uniformity of level of peaks in the same district is then discussed, and it is argued that the cutting of valleys in a mass undergoing denudation influences the heights of the peaks along the valley-walls After a long time, where the hardnesses of the rocks concerned do not greatly vary, the upstanding points at any given distance from the centre of the chain will tend to be reduced to much the same level above the sea, and the impression given will be that they were originally points on a continuous dome It is clear that the author here asks us to be cautious in applying the fascinating doctrine of the "peneplain" and of subsequent elevation to every dissected highland

The consideration of the post-Pliocene uplift leads us on to the vigorous and partly post-Roman depression of the Adriatic region, with the compensating elevation of the Apennines, then follows a survey of river-courses in central Europe The movement of masses of land in vertical blocks, to which geomorphological studies in the Alps have directed attention (p 36), is shown not to be inconsistent with horizontal movements, and with folding, where one block rides over another (p 34) The relative importance of vertical movement and horizontal thrusting, and how far the one may be a manifestation of the other are left as problems for the future

So far, the results of recent observation, geographical it may be, but with a remarkably geological trend, have been summarised for the region of which Vienna is the natural centre A few words in praise of observational research conclude this section The title of the pamphlet is, however, really justified in the discourse to the students of Berlin which opens with a somewhat depressing picture of their natural environment Men, not mountains have made the greatness of the geographical school of northern Germany Prof Penck contrasts the influence of Karl Ritter, who regarded the earth from the point of view of its suitability for man with the later and more scientific attitude of von Richthofen In each case the geographical outlook depended on the stage reached contemporaneously in the development of scientific thought Ritter expressed (p 47) the teleological views of his time, Richthofen "nimmt die Erdoberfläche nicht als gegeben, sondern als geworden, naturgemass daher bei ihm die enge Fühlung zwischen Geographie und Geologie" Followers of Richthofen should insist on being observers, not mere critics and coordinators Modern means of communication have made travel a matter of money only, instead of both time and money, as in bygone years The small scale of the maps of the more recently explored countries masks the immense amount of work that is waiting to be done, and the district adjacent to a colonial railway station may well reward the student who goes out skilled in observation With such stimulating words Prof Penck enters on his new province in Berlin, and he may be sure that his friends in the four corners of the world will welcome those whom he has trained

GRENVILLE A J COLE

THE STRENGTH OF MATERIALS

Text-book on the Strength of Materials By S E Slocum and F L Hancock Pp xii+314 (Boston and London Ginn and Co, n d) Price *12s 6d*

THIS book is intended to provide for the needs of engineering students both in the class-room and in the laboratory, hence it is divided into two parts, the first part treating of the theoretical side of the subject and the second dealing with the experimental side The first two chapters are devoted to a general discussion of the relations between stress and strain as an introduction to the development of the more special rules applicable to the structural forms in common use by engineers and architects There is an unfortunate slip on p 10 in the paragraph dealing with the fatigue of metals, in quoting some of the results obtained by Bauschinger in his experiments, the material is stated to have been "cast iron"—it was, of course, "wrought iron" Chapters iii and iv deal with stresses and strains in beams, and there are two useful constructions not usually found in text books on this subject, namely a graphical method of finding the centre of gravity and the moment of inertia for a rail, or other similar section, and a graphical solution of the problem of finding the moment of inertia of a reinforced concrete beam of rectangular cross-section

In dealing with the flexure of beams in chapter iv, the problem of continuous beams is fully discussed, and, in addition to the method of three moments, other methods of solution of the problem based on Maxwell's theorem and on Castigliano's theorem, are explained

In the next two chapters the design of struts and shafts is dealt with, also the theorem of helical springs but there is nothing novel in the treatment of any of the problems which have to be solved

In the chapter which treats of the strength of spheres and cylinders under uniform pressure, a neat formula is obtained for the critical pressure just preceding collapse in the case of a hollow circular cylinder subjected to external pressure, and Lamé's formula for thick cylinders is deduced

Two subjects—flat plates and hooks—which in most of the text-books are usually treated in a somewhat unsatisfactory fashion are thoroughly investigated in chapters viii and ix, in the case of crane hooks it is pointed out that the ordinary assumption that the distribution of stress is the same as in a straight beam subjected to an equal bending moment and axial load is not even approximately correct From an analysis of the stresses in a curved piece subject to pure bending strain, a general formula for

the case of a crane hook is deduced, and the method of Résal is explained by which the application of the formula is much simplified The last two chapters of this section are devoted to arches and arched ribs, and to foundation and retaining walls, this is a part of the subject of the strength of materials which generally proves a great stumbling-block to the engineering student, and the authors are to be congratulated on the lucid and thorough fashion in which they have set forth the various solutions which have been found most satisfactory for problems which have been well-known subjects of controversy among engineers and mathematicians for a century or more

The six chapters of part ii are devoted to the physical properties of materials and the most modern methods of determining accurately the various physical constants required in the formulæ of part i Typical testing machines are illustrated and explained, and the various types of apparatus in general use for measuring the stresses in the material undergoing test are described The materials dealt with include iron and steel, reinforced concrete and the other building materials employed by engineers and architects, a number of useful tables are given, and also the standard specifications proposed by the American Society for Testing Materials

The authors have succeeded in producing a new English text-book in which the important subject of the strength of materials, the foundation upon which the whole structure of engineering science is based is treated in a far more complete and thorough fashion than has been the case in the majority of the text-books hitherto available to the engineering student and certain sections of it should prove of great service to those who are actively engaged in engineering design

SCIENCE IN POETRY

Nature Knowledge in Modern Poetry By Alexander Mackie Pp vii + 132 (London Longmans, Green and Co 1906) Price 2s 6d net

IN this book the author deals in a very interesting manner with the many references to the aspects of nature in the poetical works of Tennyson, Wordsworth, Matthew Arnold, and Lowell

We find these poets taking delight in alluding to animated nature in many different ways Not only do flowers, trees, and foliage of all kinds occupy a prominent place in their poems, but animal life figures almost as importantly, birds more especially

Tennyson's references to horses and dogs show an intimate knowledge of these animals, though they do not convey the spirit of one in the habit of taking part in sport, and the author points out that Tennyson was not a sportsman Matthew Arnold's love of dogs is also very obvious, and his poems show how much sympathy he had with them, and what a close observer he was of their ways and habits This comes out more especially in the poems dedicated to his household pets

Interest in the insect world is shown to a greater extent by Tennyson, for he alludes to it frequently, and always with the accuracy which reveals great knowledge Lowell refers more especially to the bee

Love of bird life is common to all these poets, but it is worthy of note, and also pointed out by the author, that the great characteristic of Tennyson's work is that he describes the bird's *notes* to a great extent, and has the happy knack of so doing that the bird he is referring to is unmistakable

We gather in many ways that Tennyson was the more truly scientific man of the poets referred to The character of his allusions and the accurate detail into which he goes are, moreover, beyond the knowledge of the casual observer Wordsworth was more an esctatic admirer, as the author tells us, "his outlook was broader and in one sense less intimate" than Tennyson's He was accurate in his descriptions, but seemed almost fearful lest an intimate knowledge should do away with the beauty and poetry of nature He says,

> "Sweet is the lore which Nature brings,
> Our meddling intellect
> Misshapes the beauteous forms of things,
> We murder to dissect"

And again,

> "Enough of Science and of Art,
> Close up those barren leaves,
> Come forth and bring with you a heart
> That watches and receives"

In the preface to "This lawn a carpet all alive," Wordsworth appears a little more in sympathy with science, but in spite of this he still conveys the feeling that he is of opinion that nature will reveal her mysteries unsought

Tennyson's love of geology is apparent in the frequent references to it and the similes he gives, which clearly show he must have read a good deal on this as indeed on many other less popular subjects for instance he does not shun allusions to the nebular hypothesis spectrum analysis, and astronomy It seems evident that he accepted the theory of evolution for many quotations might be made to show it, but the author contents himself with the following, from "Locksley Hall Sixty Years After"—

> "Evolution ever climbing after some ideal good,
> And Reversion ever dragging Evolution in the mud
> * * * * * *
> Many an aeon moulded earth before her highest, man, was born,
> Many an aeon too may pass when earth is manless and forlorn"

We see, therefore that these poets deal largely with things of scientific interest, and all lovers of nature will find the book of great and permanent value

OUR BOOK SHELF

Geometrische Kristallographie By Ernst Sommerfeldt Pp x + 139, illustrated (Leipzig W Engelmann, 1906) Price 7s net

THE closing decade of the last century witnessed much progress made in the development of the geometrical theory of crystal structure, and we may now have confidence in the certainty of our knowledge regarding the possible types of crystalline

symmetry This advance has not been without marked influence on the methods of determining the physical properties of crystals The old idea to consider a crystal is a solid bounded by plane faces, the relative positions of which harmonised with Hauy's law of rational intercepts, is giving way to the more logical principle that a crystal consists of a homogeneous arrangement of discrete particles in space Indeed, as has been frequently pointed out, a theory which ignores the internal structure cannot avoid the difficulty presented by a peculiar case of pseudo-trigonal symmetry To the new school, which is typified most completely by Schonflies's well-known treatise, the present work belongs

Dr Sommerfeldt devotes a considerable portion of his book to the determination of the thirty-two classes of crystal symmetry He establishes the four possible types of axes of symmetry in the usual way, and proceeds to evolve the classes in the following order —the holohedral groups, the merohedral groups, comprising those possessing centres of inversion those without such centres, but having mirror-image symmetry, and, lastly, those without such centres, and enantiomorphous In the discussion a modification of the "Fundamentalbereich" of Schonflies is introduced It is the smallest spherical triangle defined by the elements of symmetry The symmetry pertaining to each class and the shape of typical simple forms are clearly illustrated by means of the admirable plates, of which there is one for each class except that devoid of symmetry After a brief discussion of the zonal law and the linear and stereographic projections, the author proceeds to what he considers not the least interesting portion of the book, namely, the application of the methods of vector analysis to crystallography This form of mathematical analysis is undoubtedly graced by elegance, and presents the generalised formulæ in neat guise, but its unfamiliarity to the ordinary student of crystallography seriously militates against the general utility of the book The formulæ in question some of which by the way, do not lend themselves readily to arithmetical computation, and are, therefore not of immediate practical use—could be established without greater difficulty by means of ordinary analytical geometry Nevertheless, to the advanced student who may be versed in mathematics it would be interesting and stimulating to study a different method The book concludes with a very complete bibliography and a good index

Untersuchungen über kunstlichen Parthenogenese und das Wesen des Befruchtungsvorgangs By Prof Jacques Loeb German edition, issued with the author's cooperation, by Prof E Schwalbe Pp viii+532 (Leipzig J A Barth, 1906) Price 7 50 marks

THE greater part of this remarkable book appeared in English dress in the Decennial Publications of the University of Chicago, and has been already noticed in our columns As is well known, Prof Loeb set himself some years ago the task of discovering chemical or physical methods of stimulating development in unfertilised eggs Taking every precaution which he could conceive of he has been able to induce artificial parthenogenesis in the ova of sea-urchins, of the annelid Chætopterus and of the gasteropod *Lottia gigantea* He thinks that the list will be added to as our mastery of the technique increases, for he does not believe that there is any essential peculiarity in those ova which develop in response to the artificial stimulation As to the nature of the stimulation Loeb is more and more convinced that it depends on setting-up or increasing oxidation processes in the ovum, and also on the synthesis of nuclein substances from the protoplasmic materials It is possible, he says, that the two processes are interdependent, and that oxidative syntheses take place Everyone will wish more power to this ingenious experimenter's elbow in his untiring efforts to gain control of life

Handbook of Metallurgy By Dr Carl Schnabel Translated by Henry Louis Vol ii Second edition Pp xvi+867, illustrated (London Macmillan and Co, Ltd, 1907) Price 21s net

PROF LOUIS is to be congratulated on the completion of the translation of the second edition of Dr Schnabel's great work Little delay has been experienced in placing it in the hands of English metallurgists, as the corresponding German edition was not published until 1904 The volume which has just been issued contains the metallurgy of zinc, and shorter sections on cadmium, mercury, bismuth, tin, antimony, arsenic, nickel, cobalt, platinum, and aluminium As the first edition appeared nine years ago, there have been great advances in the metallurgy of some of these metals since it was written, and these have caused many alterations and a considerable enlargement in the present volume The changes are distributed throughout, the whole text having been carefully revised, but some of the most striking changes occur in the sections devoted to the production of aluminium on a large scale and to the electrolytic treatment of zinc Electrolytic methods generally are fully treated, the author expressing his indebtedness to the works of Dr Borchers for much of this part of the book

There is little to be said in criticism of Dr Schnabel's book The description of alloys is usually rather meagre, with curiously slight regard to the work of the last twenty years Then, again the rapidity with which the Silesian zinc furnace is giving place to the Belgo-Silesian furnace does not seem to be realised by the author In general however the information is full, accurate and up to date, and is conveyed in a pleasant, readable manner

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications]*

The Inoculation Accident at Mulkowal

I SHOULD like to direct the attention of your readers to this matter The evidence regarding the unfortunate Mulkowal accident as given in the *Lancet* and the *British Medical Journal* for February 2 and in the *Journal of Tropical Medicine* for February 1, shows that on October 30 1902 nineteen persons were inoculated from a single bottle of Haffkine's prophylactic labelled 53N while numerous other persons were inoculated from other bottles A week later all the nineteen inoculated from bottle 53N developed tetanus and subsequently died while none of the others suffered at all This gives a strong argument in favour of the view that the poison was associated with the contents of that particular bottle, but the evidence is clearly not mathematically absolute even on this point while it gives no indication whatever as to when the tetanus bacillus entered the bottle It might possibly have entered during the processes of manufacture and bottling or later through a loosened cork or in several ways during the opening of the bottle and the inoculation of the contents But the commission that was appointed to consider the subject seems to have somewhat hurriedly adopted the conclusion that it actually entered during preparation and not later Mr Haffkine as head of the laboratory, was

blamed, especially because he had omitted, for good reasons, to add carbolic acid to the prophylactic. Great alarm was produced. The idea that the poisoning was due, not to local accident, but to carelessness at the laboratory, caused, I have been told, a sudden and wholesale rejection of the invaluable vaccine by the people, with the probable result that thousands of lives may have been lost from plague.

Now it appears that the tetanus bacillus could not have entered the bottle at the laboratory at all! I agree with Prof. Simpson (*British Medical Journal*, February 9) in thinking that the arguments on this point are extremely strong. Had the contents of the bottle been polluted at the outset, they would have had a very offensive smell when used some time later, and would have produced a very rapid infection in the inoculated. As a matter of fact they had no smell, and produced a slow infection, while bottles filled simultaneously were quite sound. Moreover, evidence has been given tending to show that the prophylactic was polluted during the opening of the bottle. On what grounds, then, were the laboratory and its director indicted? Even if the bacillus had entered during the complicated process of manufacture the blame can hardly be attached to the director, who cannot himself superintend the preparation of each bottle. As for the omission of the carbolic acid, the inventor of the prophylactic was himself surely the best judge of how it was to be made.

The serious part of the affair seems to lie, not so much in the loss of life due to the accident itself, considerable as that was, but in the much greater loss which probably followed the suspicion thrown upon the prophylactic by the apparently erroneous judgment of the commission, and more even than this in a certain ingratitude shown in India to a man who is one of the very greatest benefactors it has ever had. Haffkine not only elaborated the method of immunisation by dead culture, but where many a man of science would have contented himself with merely writing an article on the subject, he addressed himself on the contrary, to the much more difficult practical verification. I well remember when he arrived in India with his anti-cholera vaccine and by his energy and perseverance gradually forced his ideas upon the people and the Government. When the frightful calamity of the plague overtook the country in 1896, largely in my opinion owing to the inadequacy of the sanitary organisation and to want of firmness and resolution in the authorities, when measure after measure failed and the people were dying by hundreds of thousands, then Haffkine was the only one who made any successful stand at all against the storm. Quickly inventing his anti-plague prophylactic and forcing the authorities along with him, though he could not control the disaster, he at least checked it by saving thousands, if not hundreds of thousands of human beings who now owe their lives solely to him. The fact that more than six million doses of the prophylactic have been issued in India alone attests the success and magnitude of his work. Yet he has received for it less than nothing. For services which compared with his are really of a trifling nature all kinds of officials receive in many cases pensions, promotion, and decorations. As for him, not only has he received no adequate recognition for his immense service, but he has been blamed for an accident which could not have been due to his fault, and it is doubtful whether he will ever return to a country which has treated him—I can only say—so ungratefully. Contemplating this history, we cannot help being filled with indignation at it. India seems to be becoming quite notorious for its treatment of scientific workers, suggesting ignorance both of science and of the importance of science. I remember the persecution suffered by Colonel King as the result of his work on vaccination, the complete want of gratitude shown to Mr. Hankin for his great work on the prevention of cholera, and several similar cases. While all kinds of people climb easily into the seats of honour, it seems that the men of real merit are fortunate if only they can escape without censure.

I think I shall be excused for writing somewhat strongly on a subject on which I have long felt still more strongly, and on which I have reason to know many others feel as strongly as myself without being as free as I am to express their opinions. It appears to me a foolish thing for a nation to treat great men as we have sometimes treated ours, and the case of Mr. Haffkine—to whom, as he is a foreigner, we are doubly bound to show national gratitude—seems to be a glaring example of such treatment. I hope that steps will be taken to press upon the India Office the need for a reconsideration of the affair; the reputation of the whole country is concerned in it.

March 19. RONALD ROSS.

Mean or Median.

THE article by Mr. Francis Galton in your issue of March 7 entitled "Vox Populi," is exceedingly interesting, and the variations in the estimates of individual competitors afford an admirable instance of the advantage to be derived from the use of the weighbridge at live-stock markets in preference to buyers and sellers relying on their own judgments, but the letter raises several interesting points as to the theoretical treatment of statistical data, to two of which I should like to allude.

In the first place as to bias. No doubt, in estimating carcase weights in such a competition as that referred to by Mr. Galton each competitor judges as truly as he can. But has a butcher (buyer) had his judgment to any extent warped in the course of years through having constantly had to judge of the weight of a beast (when buying) so as to be on the safe side, and secure himself from loss in the event of its not cutting up so well as he anticipated? If so, it might be expected that buyers would have an instinctive tendency to under-estimate the weights of animals, and similarly farmers (sellers) might be expected to over-estimate. This tendency on either side should, of course, not be large, as constant intercourse between buyers and sellers has raised such transactions almost to the point of a fine art. I should therefore like to ask Mr. Galton whether he has any information showing the proportion of these 787 competitors who were farmers and butchers respectively. It is very interesting to observe from the figures given that the estimated weights at each decile are throughout the whole series invariably below the weights which might be anticipated from the normal law of error. This rather looks as if buyers were in a majority in this competition, a not impossible suggestion, since although farmers doubtless attend such exhibitions in larger numbers than butchers, yet the latter would, in a weight-judging competition, probably be more numerous than the former, at least relatively if not actually.

The second, and more important point to which I desire to direct attention is the use of the median in this connection, and I could wish that Mr. Galton had also calculated the arithmetic mean of the 787 observations. I should in fact like to strike a note of hesitation in regard to the too general use of the median in preference to the mean. The former has several advantages, one of which is that it is a form of "average" which can be very readily calculated. It is also very useful in cases such as those referred to in Mr. Galton's letter in NATURE of the preceding week, where it is desirable to eliminate one or two "cranks" whose opinion might have undue weight among a relatively small number of other opinions; in cases, in fact, where the distribution of opinions is known to be very erratic. But is this the case here? I am not sure that Mr. Galton is quite right in regarding the present instance as a case of "vox populi" at all. It is to be remembered that the great bulk of the trade in English cattle—and consequently the determination of the price of our native beef—is the result of transactions such as the competition in question is intended to test. Cattle are practically sold by inspection, and the judgment of buyer and seller as to how much beef there is in a given ox is really much more a matter of skill than of popular judgment; their livelihood depends upon the accuracy of such judgments. In such circumstances is the median a nearer approximation to the truth than the mean? Here the question could be answered by calculating the arithmetic mean. I have not the actual figures, but judging from the data in Mr. Galton's article the mean would seem to be approximately 1196 lb., which is much closer to the ascertained weight (1198 lb.) than the median (1207 lb.).

I should accordingly like to ask Mr. Galton whether he would indicate what, in his opinion, are the chief considerations to be taken into account in giving preference to the mean or the median as the better measure of the "average"? It is a point upon which there is considerable difference of opinion, the recognition of the median is rapidly extending, and some statisticians incline to think that there is a growing tendency to quote it in cases where the ordinary arithmetic mean is preferable.

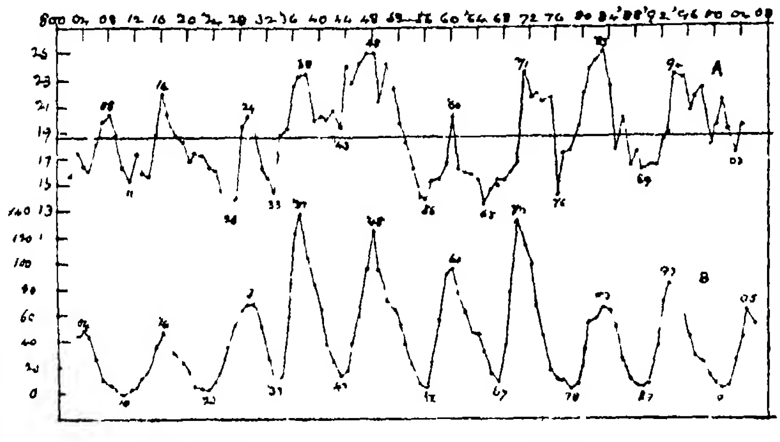
March 16. R. H. HOOKER.

Rothesay Rainfall and the Sun-spot Cycle.

THE rainfall of Scotland has been thought to show in its variations, an influence of the sun-spot cycle of eleven years (in the sense of most rain about maxima). Evidence of this was furnished not long ago by one of our ablest meteorologists, Dr. Buchan, in a paper to the Scottish Meteorological Society (Journal, 3 ser., Nos. xviii.–xix., p. 117).

For such an inquiry the record of Rothesay in Bute is singularly valuable, extending back as it does to the year 1800 in unbroken series.

The relation to the sun-spot cycle may be traced, I think, not only in the total annual rainfall of Rothesay, but also, with more or less distinctness, in the amounts for certain sections of the year, and even individual months.



A, Rainfall July, Rothesay, 1800–1906, smoothed with sums of *five*; B, sun-spot curve.

Thus it is met with in the rainfall of summer, and especially that of July.

I have prepared a curve of the July rainfall (A) in which, by a familiar method, each year-point represents the rainfall of five contiguous Julys (*i.e.* 1800–4, 1801–5, and so on). Below is the sun-spot curve (B). The amount of correspondence between these two seems remarkable, and not easily explained by fortuitous coincidence.

ALEX. B. MACDOWALL.

The Relationship between Diamonds and Garnets.

IN an able paper entitled "The Diamond Pipes and Fissures of South Africa" read before the Geological Society of South Africa rather more than a year ago, Mr. H. S. Harger refers more than once to the significance of the fact that diamonds have been found embedded in garnets. Perhaps the fact that the converse is also true, namely, that the garnet sometimes occurs embedded in the diamond, may not be without its share of interest. I have here at the present time a fragment of a Wesselton diamond, weighing a little more than a carat, containing a small, irregular garnet of about one-tenth of a carat. Originally the fragment seems to have formed a part of a shapeless diamond of perhaps two carats, which evidently enclosed either two or three small garnets, or garnets and diamonds.

J. R. SUTTON.

Kimberley, South Africa, February 20.

THE WEATHER REPORTS OF THE METEOROLOGICAL OFFICE.

THE commencement of the new year was marked by the introduction of a number of changes in the weather reports of the Meteorological Office.

Two notable events have contributed to bring about modifications in the daily report. Arrangements have been made for regular telegraphic reports from Iceland, and for occasional reports by wireless telegraphy from the ships of the Navy.

Thanks to the Danish Government and the Great Northern Telegraph Company, the cable to Faeroe and Iceland, long desired by meteorologists and fishery associations, was laid in the summer of last year. There is a touch of sadness in the reflection that Adam Paulsen, director of the Danish Institute, who led the way so assiduously towards this meteorological Canaan, only got a distant view of the promised land. In August, 1906, he issued a circular on behalf of the Danish Government, defining the terms of subscription for the service of meteorological telegrams from Iceland, but, as already reported in NATURE, he died before the arrangements were completed.

Reports from Thorshavn in Faeroe and from Seydisfjord, on the east coast of Iceland, have been received in London, in a provisional way, since the end of October, but the meteorological telegrams from Reykjavik, on the west coast, commenced on Friday, February 15, as part of the full system which includes messages from Blonduos and Akureyri, where the land line touches the northern fjords, and Grimstadir, between the last-named place and Seydisfjord, where the cable lands. The meteorological arrangements are not complete even yet, for the reports do not conform to the established international model, either in uniformity of the hour of observation or the extent of the information transmitted, but those who have seen what the new information means for the weather map of north-western Europe, what light it throws upon the meteorological situation of the northern Atlantic, will appreciate the satisfaction that is felt with the result of the negotiations even in their present stage. Paulsen has indeed carved for himself a memorial *aere perennius* upon the winds and weather of the stormy northern island.

It is to the Lords of H.M. Treasury that we owe the realisation of this long-cherished project so far as this country is concerned. It need hardly be said that the cost of the new service is very considerable. Their lordships have undertaken to ask Parliament to increase the grant for meteorology from 15,300*l.*, the figure at which it has stood since 1882–3, by 200*l.*, and the greater part of our share of the expenses for Iceland telegrams is thus provided for.

In order that the new information may be incorporated in the daily weather report the area of the charts has been extended to a more western longitude than hitherto, and the occasion has been utilised also to take in an area as far south as Gibraltar, and to meet a wish often expressed that a barometric chart of the 6 p.m. observations of the previous evening should be given. This appears as an inset chart on the same scale as "yesterday's" 8 a.m. chart for the whole of Europe, side by side with the 8 a.m. chart for "to-day." But six o'clock observations

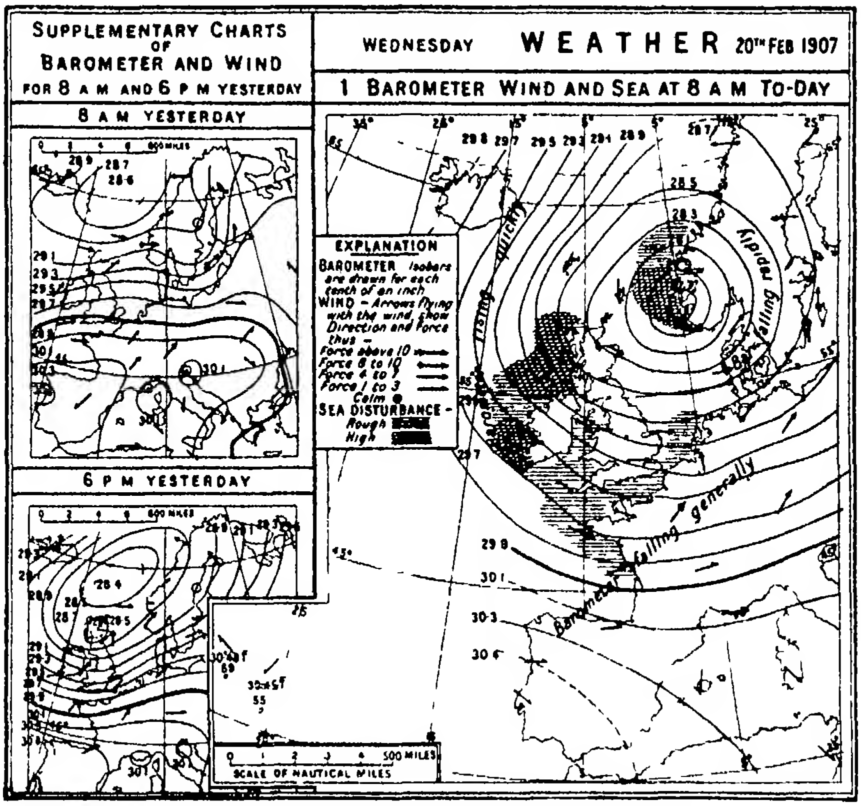
are only received by telegram from western Europe, and the eastern portion of the map would always be blank. Advantage is taken of this misfortune to get a western extension of the lower part of the 8 a.m. barometric chart, and thus provide for the observation from the Azores, for which we are indebted to Major Chaves and the Portuguese Government. It happens that the eastern point of the Azores and the western point of Iceland lie close to the meridian of 25° W., and it is a matter of importance to get observations from both these "centres of action" on the same chart. The bringing of Iceland into touch with Europe by the new telegrams emphasises the isolation of the Azores, and the chart is a pathetic appeal for the extension of the area to be reached by wireless telegraphy. But in the meantime the daily problem of drawing isobaric lines to connect the Azores pressure readings with the European and North Atlantic distribution affords an intellectual exercise which would bear comparison with some subjects of competition judged worthy of valuable prizes.

In order to represent the new arrangement of p. 2 the barometric charts for the issue of February 20 have been reproduced, completed for observations missing on the day. They show the development of the storm which caused the *Berlin* disaster at 6 a.m. on February 21.

The extensions of the daily charts have been carried out without sacrificing any of the information hitherto given on the inner pages of the daily report, except the map of weekly results which has occupied a place on p. 2 for some years. On p. 4 the table of hours of observation has gone to make space for wireless telegrams, for which arrangements have been made through the courtesy of the Lords of the Admiralty. Only two messages have appeared as yet, but they have been enough to show that the system, which needs careful organisation in order to avoid disastrous results arising from instrumental or telegraphic errors, is capable of satisfactory working.

The weekly report has been enlarged by two additional pages. The new features introduced last year have been continued. They include temperatures on the grass and in the ground, from a considerable number of stations, and observations in the upper air contributed by Mr. W. H. Dines from his new station at Pyrton Hill, Oxon., Mr. C. J. P. Cave of Ditcham Park, Mr. S. H. R. Salmon of Brighton, and Mr. J. E. Petavel, for the physical laboratory of the University of Manchester, working at Glossop Moor. To these have now been added a table of temperatures of the sea, at coastguard stations and elsewhere on all coasts. No one doubts the influence of the sea temperature upon the climate of this country, but few attempts have been made to deal with the numerical results. The tracing of the relation of sea temperature to the incidence of sea fog is the direct object of the new departure in obtaining the readings weekly instead of monthly as hitherto.

But the most important addition to the report, although it makes little show, is on the new front page. It is the first result of an attempt to deal with climatological work from the point of view of frequency distribution. The weather of the week for each of the twelve districts of the British Isles as regards warmth, rainfall, and duration of sunshine is characterised by a selection of adjectives for each element. To do this the results for the current week have to be referred to the mean values for the corresponding week, which are smoothed to give appropriate averages "for the time of year." The trouble is to define the characteristics of a week in such a way that when the weeks of a particular kind come to be counted for a season or a year, the result shall not be misleading. This seems at first sight an easy matter, but the frequency distribution of the values of the elements introduces a difficulty that is curious and interesting.



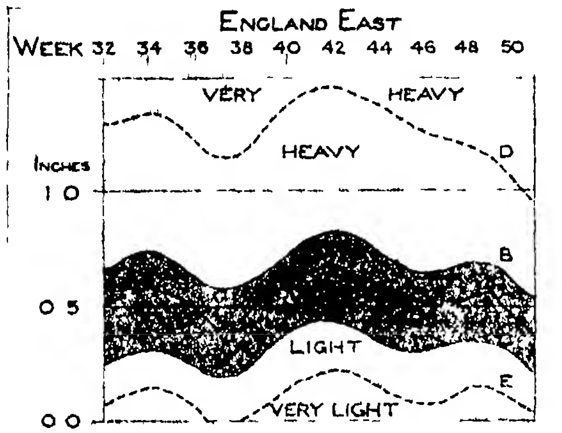
Form of the new Daily Weather Report of the Meteorological Office.

Take as an example the rainfall in a district like that of the eastern counties. The mean value for the week is by no means the most frequent value. The commonest kind of week is one with very little rainfall, and the frequency of weekly falls of successive intensities is less and less until we come to rare weeks of very heavy rainfall. The mean rainfall belongs to a group which is comparatively infrequent. Consequently, if we call a week with less than average rainfall a dry week, and it seems at first sight reasonable to do so, we shall find that in an ordinary season most of the weeks appear as dry

ones, and they are balanced by the heavy rainfall of a few wet weeks.

Thus in characterising weeks for counting it is necessary to deal with probable frequency of occurrence as well as with the relation of the week's fall to the average depth of rain. Frequency results are most easily expressed by odds. It has been sought to determine limits for a week of so-called "heavy" rainfall so that the odds are two to one against its occurrence, and the same for "light" rainfall. Further "very heavy" rainfall has been so defined that the odds are eleven to one against its occurrence, and "very light" in a similar way.

To determine the limits for these odds the weekly values for the twelve districts for the twenty-five years 1881 to 1905 have been dealt with. Smoothed mean values for each week have been obtained, and frequency results for groups of six or seven weeks, to get a sufficiently large combination of values to make the odds a reasonable representation of the probabilities of the case. Limits are then chosen so that of the whole number of rainfall values for a group of weeks, one-third are moderate, one-third heavy, one-twelfth very heavy, one-third light, one-twelfth very light. Sunshine and accumulated temperature above and below 42° are treated similarly. The adjectives selected for sunshine are "abundant" and "scanty," and for warmth "unusual" and "deficient."



Classification of Weekly Rainfall.—Portion of diagram for the District "England East" for the period from the 32nd to the 51st week. The line A is the smoothed 25 year average of the weekly rainfall. If the rainfall for any week fall within the central shaded belt, it is characterised as "moderate," if it fall outside this belt it is either "heavy" or "light"; if it fall above the dotted line D or below the dotted line E the word "very" is prefixed to the designation. The limits are so adjusted that ⅓ of the values for the 25 years 1881–1905 fall below the line C, ⅓ between the lines B and C, and ⅓ above the line B. One twelfth of the values fall above or below each of the limits D and E.

The work necessary for obtaining these limits has been very heavy, but incidentally a number of interesting points about the weekly values for the elements in the several districts and the frequency distributions have been disclosed which will be the subject of an official publication on the seasons in the British Isles.

The monthly report which began with the January number issued at the end of February, shows less change than was anticipated at one time. Negotiations were initiated with the view of making it a complete index of climatological work for the British Isles, to contain a line of data for each station contributing observations to the Meteorological Office, the Royal Meteorological Society, and the Scottish Meteorological Society. At present the three bodies collect and publish observations independently, but if a joint publication could be arranged, any person requiring climatological data would be able, by reference to a single publication, to know what information was in existence and where it was to be obtained. Unfortunately difficulties arose which could not be overcome in time, and as regards climatology the Report for 1907 is limited to the 170 stations in direct or indirect connection with the office. But Dr. H. R. Mill, the director of the British Rainfall Organisation, has expressed his willingness to contribute a rainfall map of isohyetal lines based on the monthly results for about 500 stations in the British Isles, and in the current issue this replaces the map showing rainfall values at the 170 stations which have always been regarded as too few for drawing isohyetal lines.

It ought, perhaps, to be added, as regards the daily weather report, that it is prepared and printed at the public expense, and is sent free to anyone who pays the cost of postage, wrappers, and addressing. Complaint has sometimes been made that it is not advertised as it should be, but as a matter of fact the "advertisable interest" rests with the Post Office. For the weekly report with which the monthly is included a subscription is charged to meet the cost of printing. But this report gives so compendious a statement of the weather in the British Isles, daily, weekly, monthly, quarterly, annual and average, in an annual volume of about 450 pages, that it ought to find a place in every reference library. It has now been in existence for more than twenty-five years, and its value as a homogeneous body of statistics increases with every additional year. Its weekly pages are too much like pemmican to be attractive to the general reader, but a disturbing reflection about the matter is that when its life has continued for fifty years, and the public becomes educated to appreciate its uses, there will be no means of meeting demands for the numbers which are now regarded as being merely of interest to the curious meteorologist.

TECHNICAL TERMINOLOGY

AN interesting feature of the progress of engineering science has been the gradual formation of the engineering vocabulary. Ever since the days of the early constructors there has been a steady application of fresh terms to technical practice, and it is not difficult to trace the methods by which this has taken place. But the process has operated to such an extent that what could almost be called a new language has arisen, and specimens could be quoted from the best examples of engineering literature which to scholars of a century ago would convey no meaning, though the origin of each individual term might be at once apparent to them.

Some of these terms have interesting histories by reason of the changes of sense they have passed through. The word "skid," for example, was originally the name of the buffer rope hung over a boat's side to protect it from injury. It was then applied to the shoe placed under a wheel to brake the motion of a carriage, and finally it was turned into a verb to express the vagaries of vehicles in muddy weather. "Switch" first applied in railway practice and connected with the peculiar motion of the bar so named was passed on to electrical machinery. The "salamander" is a newt of a kind supposed, according to an old legend, to be capable of living in fire. The newt, surrounded by his flames, is sometimes seen in heraldry, and from this source it was applied to certain kinds of foundry irons and crucibles. "Splay" is borrowed from architecture and in its original sense means an obliquity or bevel edge. The bevel edge is frequently used to expose some interior part, and hence the

origin of the term, which is simply a contraction of "display." The "tender," or attender, of the vessel or locomotive, and the "tender" supplied by the contractor, though of such different meanings, are derived primarily from the same Latin word, meaning "to reach out." On the other hand, the verb "fuse" comes from the Latin, meaning "to pour," and the noun "fuse," together with "fusee," from a word meaning "spindle." It is interesting to note that several words, such as magnetic, type, amalgamate, wire, and cable, have been borrowed from the technical vocabulary and applied to the language of ordinary affairs, and no doubt as mechanical appliances enter more and more into the essentials of social existence this process will be increasingly carried on. Perhaps the most interesting history of all is that of the word "pole," as used by electrical engineers. Its original is a Latin term meaning simply an axis of rotation. From this it has been applied to the particular axis on which the earth rotates, thence to the two points on that axis of special interest, to the ends of a suspended magnetic needle, and so to the points of intensity of any magnet. By analogy it has finally been applied to the terminals of an electric cell, and it is hard at the present day to see in its application—whether to the battery or the dynamo—any likeness to the original sense of the word.

Many of our oldest terms have simply accompanied the ideas they express into engineering practice from architectural, nautical, smithy, and domestic uses. Examples are swivel, lathe, pump, gauge, list (from the same root as "lust"), fish-joint, brake, and most of the terms connected with masonry construction. Some of Latin origin are interesting, *e.g.* piston (pinsere=to pound, *cf.* "pestle"), camber (camerare=to enclose or vault), filter (filtrum=felt), and vice (vitis=the tendril of a vine). Some are derived from European languages: scarf (Scand. skarf=a joint), cam (Dut. kam), bush (Dut. bus=a box), ratchet (Eng. rack), calipper (Eng. calibre), and jetty, rabbet, tunnel, pulley, quoin, from the French. Others the derivations of which have never been traced are sprocket, cotter, journal (in the mechanical sense), and spline.

Of the methods employed to-day for christening new engineering conceptions the favourite is the use of analogy. Probably more than a third of our expressions have been introduced in this way. In many the analogy is obvious—sleeper, bed, jacket, feed, booster (a U.S. colloquialism). Some are due to a likeness in appearance—crane, nose, shaft (from the arrow), groin (from its position), muff, worm, others to a similarity of function or movement—deadbeat, torpedo (the name of a fish), dog and jack (originally applied to any domestic implements of humble usefulness), pinion (from the joint of a bird's wing), valve (from anatomy), and siren (originally "one of certain sea-nymphs, who ... sang with bewitching sweetness," dictionary!). In one or two the analogy is more subtle. Thus a "washer" is really a kind of lubricant, and so was considered to resemble the film of water between the hands in washing. "Bogie" is said to be from "bogey," a fiend, the bogie coal-waggon being so called because from its suddenly turning when people least expected it, they used to exclaim that the new waggon was "Old Bogey" himself. "Steelyard," according to many dictionaries, owes its origin to the yard in London where steel was sold by German merchants, and where this kind of balance was in use.

Somewhat akin to this class are the one or two compound words we have formed—flywheel, manhole, breakwater, ingot (an ancient example, from "in" and Anglo-Saxon "géotan," to pour)—and words coined with the aid of suffixes, such as spin-dle (very old), tire (tie-r), troll-ey, tap-pet, span-ner.

Many technical terms have been formed directly from Latin and Greek words. There are old examples—pawl, carpentry, canal, cylinder, one or two of more modern date, such as electricity, annular, hydraulic, and a host of recent ones, telegraph, telautograph, microphone, vulcanite, dynamo, electrotechnics, asbestos, torque, rheostat, &c.

In general, it would seem that the terms used in construction work and machinery have been introduced mostly by the use of analogy, while the pioneers of industries—such as electrical engineering—more closely related to pure science, whose work has often been carried on in the university laboratory, have favoured the classical method in coining words.

Eight words used by electrical engineers form a class by themselves in that, instead of slowly making their way from some individual's suggestion to general recognition, they have been established by a parliament of scientific men, and have found an immediate and universal adoption. These are the electrical units. The original two—ohm and volt—were suggested by Sir C. Bright and Mr. Latimer Clark. These, together with ampere, coulomb, and farad, were made legal at the International Congress in 1881, and three fresh ones, joule, watt, and henry, were authorised by the Chamber of Delegates at the Chicago Exhibition in 1893. One striking feature of each of these words is its terseness, a virtue so often lacking to scientific expressions.

Proper names have been introduced in other ways as well. The most famous example is "macadam." Others are tramway (Outram's ways, from the inventor), galvanic, voltaic (in use before the unit was suggested), magnet, catalan (from Catalonia, the home of the catalan forge), derrick (the name of a hangman of the seventeenth century), and a queer hybrid sometimes seen in print, marconigram.

A few words have been abstracted from foreign languages. Such are quay (an old example), voussoir, turbine, barrage, tuyere (also spelt according to the dictionaries twyer, tweer, tuyer, and twier), automobile, and chassis.

About the only scientific term (outside the advertisement columns) that can properly be called an invention is the word "gas." This we owe to a Dutch chemist, van Helmont, of the sixteenth and seventeenth centuries. His explanation is that, "because the water which is brought into a vapour by cold is of another condition than a vapour raised by heat, therefore ... for want of a better name, I have called that vapour Gas, being not far severed from the Chaos of the Auntients." The word "click," formerly applied to the non-return valve, is an echoic formation, but it was not coined to describe the valve, its first use being to express the sound produced by such mechanical appliances. It seems a little strange that the engineer, whose work is so often associated with original invention, should so seldom resort to original methods in devising names for his productions.

There are still many cases of inventions that have come into general use which are badly in want of a short expressive title. Thus we have nothing better to describe the practice of signalling between mutually invisible points through the medium of the æther than "wireless telegraphy", the only name available for the class of prime mover which works by the explosion of a vapour is "internal combustion motor", and surely a handy substitute would be welcomed for "electric power supply," and some

more appropriate title for its particular vital organ than "central station." "Ferro-concrete" is certainly an improvement on "reinforced concrete," but it is a clumsy name for a material which does such important work in civil engineering. A similar case which existed until lately was the need of a substitute for "aerial navigation," but this has been most happily met by the suggested "aviation," a word which is both short in spelling and wieldy in pronunciation.

It is to be hoped that those who have to coin new engineering terms in future will follow the example of the old Dutch chemist and depart as little as possible from three-letter monosyllables. The times are growing too busy for more of the three- and four-syllabled obstructions of physicists and electricians to be tolerated.

A. H. DOWNES-SHAW.

SPORT IN CEYLON.[1]

FIFTEEN years' experience of the jungle, even though it be limited to one or two annual hunting trips, ought to suffice to make any keen sportsman (like the author of the volume before us) thoroughly familiar with the habits of all the larger forms of wild animal life to be met with in a circumscribed area somewhat smaller than that of Ireland. Mr. Storey has, however, not been content with his own great practical knowledge of the denizens of the Ceylon jungle and their ways, but has enlisted the aid of a number of his fellow sportsmen. With such an array of specialists, the book may be re-

FIG. 1.—Head of Ceylon Buffalo. From Storey's "Hunting and Shooting in Ceylon."

garded as a thoroughly up-to-date account of the sport to be met with at the present day in one of the most lovely of the islands of the East.

[1] "Hunting and Shooting in Ceylon." By H. Storey (and others). Pp. xxiii+365; illustrated. (London: Longmans, Green and Co., 1907.) Price 15s. net.

Unfortunately, this sport is nothing like what it was when Sir Samuel Baker shot and hunted in the island some sixty years ago, and if matters are permitted to go on as they are, it is the author's opinion that several of the game animals will be in danger of extermination, or at all events will be so reduced in numbers that Ceylon will cease to be a hunting-

FIG. 2.—Chital or Spotted Deer: the buck with the antlers in velvet. From Storey's "Hunting and Shooting in Ceylon."

field for European sportsmen. The two species most sorely harried appear to be the chital, or spotted deer (Fig. 2), and the elephant. As both probably represent races peculiar to the island, their extermination would be little short of a calamity.

In the case of the chital (and this also applies in a minor degree to the sambar deer) the mischief seems to be due to the killing of this beautiful animal by native hunters for the sake of its flesh, which is cured and dried. The remedy suggested by Mr. Storey is the prohibition of all trade in products of the chase within the island itself, the villagers being, however, permitted to kill such deer as they require for themselves. As regards elephants, of which the author believes there are less than two thousand in the wild state in the island, the destruction appears to be mainly due to the European sportsmen, whose exertions were formerly stimulated by a Government reward for every one of these noble animals slain.

As Ceylon elephants generally have no tusks to speak of, it is a little difficult to see why sportsmen are so keen on shooting them, and it is to be hoped that the destruction may be stopped in the near future. Wild tuskers (not improbably belonging to a race originally imported from the mainland) are now, Mr. Storey tells us, very scarce in the island, although, except in the case of "rogues," they are rigorously protected. Naturalists will be much interested in a giant race of (practically) tuskless elephants living in the Tamankaduwa district which are much larger than the ordinary Ceylon form, and commonly attain a height of between 9 feet and 10 feet.

The author's observations with regard to the wild buffalo of the northern districts of the island, and

the figures of the head he gives (one of which is here reproduced), are likewise of very great interest to naturalists, for they seem to indicate that the Ceylonese animal is a distinct local race of *Bos bubalis*. After stating that the horns are smaller and less regular in form than those of the buffalo of the Indian mainland, Mr. Storey observes that:—

"In India they seem almost all to curve boldly outward and upwards, finally curving in towards each other at the points. In Ceylon they are very irregular, and usually much shorter, though occasionally they may be more massive than Indian horns. The commonest form are those curving outwards and upwards [in] crescent form, but not with the bold, almost half-circular sweep of the Indian heads."

In this place it may be mentioned that as the author is not a photographer, he has been compelled to borrow the admirable photographs of scenery and animals with which the volume is illustrated from friends and brother sportsmen. To one of these we have already alluded; a second, showing the most beautiful of all Ceylonese animals, is reproduced as an example of the general excellence of the pictures.

Like all the big-game animals of the island, the chital is specifically the same as its Indian representative. The very fact that tigers are unknown in the island is, however, itself practically sufficient to indicate that all these animals are racially distinct from the mainland forms.

Although big-game animals naturally form the main theme, the author has something to say regarding smaller game, and likewise gives much information with regard to the physical characters and scenery of the country, while the requirements of novices contemplating a sporting trip are not forgotten. Although confessedly written from the point of view of the sportsman rather than naturalist, Mr. Storey's volume contains much which appeals to both classes, while it may likewise be commended as a delightful description of a tropical country to the general reader.

THE DEATH OF M. M. BERTHELOT.

THE tragic death of M. Marcellin Berthelot on Monday has awakened a feeling of sympathetic sorrow throughout the intellectual world. As a chemist, philosopher, a fearless exponent of scientific truth, and permanent secretary of the Paris Academy of Sciences, M. Berthelot's work and influence made him renowned among the greatest men of our time. The French nation has to mourn the loss of one of its leading citizens, and its sorrow is shared wherever knowledge and research are cherished.

Several conflicting accounts of the dramatic circumstances of M. Berthelot's death appeared in Tuesday's papers. One report states that he expired clasping the hand of his wife, who had been ill for a year and had crossed the dark river a few minutes before. According to another account, M. Berthelot was sitting in his study when the news of his wife's death was brought to him by a nurse, and he fell back in his chair dead. The *Times* correspondent states that when M. Berthelot entered his wife's room on Monday he found her dead, and the shock was so great that he returned to his study and there died suddenly himself.

France knows how to honour its illustrious men, so it is not surprising to learn that at the opening of Tuesday's sitting the French Government proposed to grant a credit of 800*l*. for a national funeral for M. Berthelot, and to adjourn the sitting as a sign of mourning. A similar expression of sympathy took place in the Senate, and the Academy of Medicine likewise adjourned its sitting. We learn from the *Times* that there will be no religious service in honour of the dead. The national civil funeral has been accepted by the family on the understanding that Mme. Berthelot should not be separated from her husband, who could not live after her.

We propose to give an account of M. Berthelot's life and work in another issue, and here limit ourselves to the expression of deep regret at his sad death, and of satisfaction that the French nation has so clearly shown its high regard for the great man it has just lost.

NOTES.

THE Goldsmiths' Company has made a donation of 10,000*l*. to the Lawes Agricultural Trust (Rothamsted Experimental Station) to be devoted to research in connection with the soil, and to be known as the Goldsmiths' Company's fund for soil investigation.

MR. A. LAWRENCE ROTCH, the founder and director of Blue Hill Meteorological Observatory, has been appointed professor of meteorology in Harvard University. The Blue Hill observations and investigations have been published for many years in the Annals of the Harvard College Observatory.

AT the annual general meeting of the Chemical Society on Friday, March 22, the president, Prof. R. Meldola, F.R.S., will deliver an address entitled "The Position and Prospects of Chemical Research in Great Britain."

MR. W. H. POWER, C.B., F.R.S., medical inspector of the Local Government Board, has been appointed chairman of the Royal Commission on Tuberculosis, in succession to the late Sir Michael Foster.

THE *Times* correspondent at Ottawa reports that on Tuesday a deputation of representative Canadians asked for a Federal grant towards the erection of a national memorial at Brantford, Ontario, in honour of Dr. Alexander Graham Bell, who invented the telephone in that city. In reply, Sir Wilfrid Laurier expressed himself in hearty sympathy with the movement.

A MINISTERIAL measure having for its object the amendment of the Patent Law was introduced in the House of Commons on Tuesday. The main purpose of the Bill is to prevent the patent laws from being used for the hindrance and suppression of British industrial development. It is proposed to simplify the procedure of compulsory licence, and instead of the applicant having to go before the Judicial Committee of the Privy Council, as at present, he will go, first of all, before the Controller and afterwards before a judge specially selected by the Lord Chancellor, who will be habitually dealing with patent cases. This method will tend very considerably to shorten the hearing of cases, because they will be dealt with by an expert judge. The Bill also provides that any applicant can go to the Controller three years after the granting of any patent and apply for the revocation of the patent on the ground that it has not been adequately worked within the United Kingdom. In addition to compulsory working, syndicates are to be enforced to deposit samples when the Patent Office requires them to do so, or else their application will be refused.

THE Geologists' Association has arranged an excursion to Plymouth from Thursday, March 28, to Tuesday,

April 2, so that members who can spend Easter in the west will be able to study the rocks and deposits of the Plymouth and Cornish areas under very pleasant conditions. The excursion secretary is Mr. G. E. Dibley, 7 Champion Crescent, Lower Sydenham, S.E.

EARL CARRINGTON, President of the Board of Agriculture, has accepted the invitation to open the second National Poultry Conference at Reading on Monday evening, July 8. The Mayor of Reading (Mr. F. Jackson) has intimated his intention to give a reception to delegates and members in the Town Hall, Reading, on that evening, when the official opening of the conference will take place.

A PRELIMINARY announcement has been issued regarding the arrangements for the fourth International Mathematical Congress, which is to be held in Rome on April 6–11, 1908. A large general committee has been formed representing the Reale Accademia dei Lincei and the Circolo matematico di Palermo. A special feature will be the organisation of lectures, or, to use the American term, colloquia, each embracing the survey of an extended region of mathematical science, and the following mathematicians have promised to lecture:—Profs. G. Darboux, A. R. Forsyth, D. Hilbert, F. Klein, H. A. Lorentz, G. Mittag-Leffler, S. Newcomb, E. Picard, H. Poincaré. The subscription is 25 francs for members, 15 francs for ladies' tickets. The treasurer is Prof. Vincenzo Reina, 5 Piazza S. Pietro in Vincoli, Rome, while Prof. G. Castelnuovo, at the same address, is general secretary of the organising committee.

THE sixtieth annual meeting of the Palæontographical Society was held at the apartments of the Geological Society, Burlington House, on March 15. The report of the council referred to the activity of students of palæontology in Great Britain at the present time, as witnessed by the number and variety of the memoirs offered for publication. Among instalments of monographs issued in 1906, one completed Mr. Reed's description of the Girvan Trilobites, and another began a new monograph of Cambrian Trilobites by Mr. Lake. The Carnegie trust for the universities of Scotland had defrayed the cost of five plates of Old Red Sandstone fishes described by Dr. Traquair. The society lost several subscribers by death in 1906, among these the Rev. J. F. Blake, who left his monograph of Cornbrash fossils unfinished. The funds had been augmented by a special sale of back stock to members, but many new subscribers were needed to raise the normal income to the amount received by the society ten years ago. Dr. Henry Woodward, F.R.S., Dr. G. J. Hinde, F.R.S., and Dr. A. Smith Woodward, F.R.S., were re-elected president, treasurer, and secretary respectively. Messrs. J. Hopkinson, W. D. Lang, H. Woods, and G. W. Young were elected new members of council.

THE Pharmaceutical Society of Great Britain has on several occasions benefited by the generosity of Sir Thomas Hanbury, whose death was announced in last week's NATURE. To the museum of the society he presented the valuable collection of ancient and modern materia medica made during many years by his brother Daniel, as well as the whole of the medicinal plants of his rich herbarium. These now occupy a special room of the museum, named the Hanbury Room. To the library of the society he presented a fine collection of scarce and valuable works on materia medica and botany, many of which are now extremely difficult to obtain. At the re-opening of the School of Pharmacy in 1903, at which he was present, Sir Thomas expressed the wish that his name should, in future, be associated with the Daniel Hanbury gold medal, which is offered biennially by the Pharmaceutical Society for original research in the natural history and chemistry of drugs, and he handed to the society securities, so that each recipient of the gold medal should at the same time be presented with the sum of fifty pounds. His generosity extended even to the School of Pharmacy, the silver medallists of each session receiving copies of "Pharmacographia" and "Science Papers," in which volumes the life-work of the late Daniel Hanbury are embodied. It is interesting to note that the munificence of Sir Thomas always had a practical aspect. His gifts were intended to help and stimulate personal effort, and were always given with discrimination after due consideration.

A SCIENTIFIC expedition under the auspices of the Royal Geographical Society, the funds for which had been found by the Alpine Club, had been arranged to explore Mount Everest from the Tibetan side. It was proposed that the party, under the command of Major the Hon. Charles Bruce, M.V.O., of the 5th Gurkha Rifles, should travel from Darjeeling north to Kampadzong, just on the Tibetan side of the Indian frontier. There it would have turned sharply and nearly due west to Kharta, from near which point the ascent was to have been commenced. Nepaul territory would nowhere have been violated. It was proposed, moreover, that the natives should have been dealt with directly by the English leaders, and that every precaution should be taken to avoid any cause of friction. The Home Government, however, refused the necessary permission. Mr. Morley, replying to a letter from Sir George Goldie, K.C.M.G., president of the Royal Geographical Society, said it was not possible, consistently with the interests of the policy of the Government for the Government of India to give encouragement or help to exploration in Tibet. Mr. Morley later in his letter made the unfortunate assumption that it was proposed to proceed "furtively" through Tibetan territory, a suggestion which Sir George Goldie repudiates very emphatically. It is conceivable that high Imperial policy should lead the Government to decide that the expedition was inexpedient, but it is difficult indeed to realise that Mr. Morley should have supposed that a body of distinguished geographers could countenance for an instant any scheme of a furtive character.

THE annual dinner of the Institution of Civil Engineers was held on March 13, when the president, Sir Alexander Kennedy, F.R.S., was in the chair. Lord Kelvin responded to the toast "Science and Literature," and is reported by the *Times* to have said it is interesting to remember that science has touched some of the noblest departments of art, for Leonardo da Vinci was one of the greatest engineers as well as one of the greatest artists of all times. Lord Kelvin also referred to the great achievements of Smeaton, the engineer of the Eddystone Lighthouse, and remarked that scientific engineering has grown up since the middle of the nineteenth century. About 1838 or 1839 the first professor of engineering in the British Empire was appointed, his chair being one established in the University of Glasgow. The demand of engineers for improved training in science has never flagged since then, and all our universities now have engineering schools. Lord Tweedmouth, in responding to the toast of "The Guests," remarked that the engineering profession

is very close indeed to the heart of the Admiralty. He referred to the services of Sir Alexander Kennedy in connection with naval construction, to the advice concerning dockyards given by Sir William Matthews, and to the distinguished work as a designer of ships of Sir William White. It is comparatively recently, he said, that the Admiralty has been so closely brought in touch with the civil engineer. But all the great works ordered by the Admiralty have been carried out by the advice of engineers.

AN unsettled type of weather prevailed over the whole of the British Islands during the past week, and the wind frequently attained the force of a gale on our coasts. A storm of more than ordinary severity was experienced in the north-west of England during the late hours of Saturday and the early hours of Sunday (March 16–17). In places on our north-west coast the wind attained the pressure of about 18 lb. on the square foot. The storm reached its greatest violence from about 9 p.m. to midnight, and afterwards the gale rapidly subsided. Unfortunately the strongest wind force was coincident with the occurrence of high water, and in consequence much damage was occasioned by wind and wave. Notwithstanding the windy character of the weather, thick fog has prevailed on our south-west coasts, resulting in the grounding of at least two large steamships, one going ashore late on Sunday night and the other in the early morning on Monday.

THE report of the Maidstone Museum, Public Library, and Art Gallery, for 1906 chronicles a very successful year, notably for the fact that presentations have been made by donors living at considerable distances from the borough. Misprints like Malay Peninsular and Osteolepus somewhat detract from the style of the report.

THE blue jay (*Cyanocitta cristata*), the killdeer plover (*Ægialitis vocifera*), and the bluebird (*Sialia sialis*) form the subject of the last three of the excellent series of illustrated leaflets issued by the (U.S.) National Association of Audubon Societies.

NEW or little-known perch-like fishes in the collection of the academy and the land-shells of the Ozark Mountains of Arkansas and Missouri form the subjects of papers in the issue of the Proceedings of the Academy of Natural Sciences of Philadelphia for December last.

AT the conclusion of an exhaustive memoir on the development of the common ring-snake (or grass-snake) published in vol. lxxxvi., part i., of the *Zeitschrift für wissenschaftliche Zoologie*, the author, Mr. Theodor Viefhaus, institutes a careful comparison to show in what respects the early stages of a number of other reptiles differ from those of the species described. The preamnion and the primitive groove are among the structures in which such differences are in many cases very notable.

THE report of the Royal Scottish Museum, Edinburgh, for 1906, contains a well-merited tribute to the services of Dr. R. H. Traquair, who retired in August last after a thirty-two-years' tenure of the post of keeper of the natural history department. Among the gifts received during the year, mention may be made of a giraffe from the Quasaengeshu plateau, British East Africa, presented by Lord Hindlip. This should be of the same race as the large mounted pair exhibited in the Natural History Museum.

TO the *Naturalist* for March, Mr. Arthur Whitaker contributes further notes on the breeding habits of British bats, and more especially the ordinary bat, or pipistrelle. July, it appears, is the great month for breeding among British bats, and it has been demonstrated that in the pipistrelle the period of gestation is not less than forty-one days, and is probably of about six weeks' duration. At birth the young pipistrelle is flesh-coloured, totally blind, and naked except for a few hairs on the muzzle. Fur begins to show in about a week, and soon after imparts a golden tinge to the back and a more silvery tint to the under parts. Even when only a few days old the young bats might be seen hanging altogether apart from their parents, but up to the thirty-first day (when the last died) they did not attempt flight on their own account.

INSECTS associated with or related to the Mexican cotton boll-weevil continue to engage the attention of the U.S. Bureau of Entomology, parts iii., iv., v., and vii. of Bulletin No. 63 being devoted to them. The most important of these is the Texan ant *Solenopsis geminata xyloni*, which attacks the boll-weevil in sufficient force to effect an appreciable diminution in its numbers. An examination made last autumn of 300 fallen squares and bolls of cotton collected indiscriminately showed that 40 per cent. of the weevils (in all stages) by which they were infested had been killed by the ants. The ant, which is widely distributed in Texas and western Louisiana, and may be found on totally different types of soil, is undoubtedly of considerable benefit as an established enemy of the weevil throughout nearly all the area at present infested by the latter.

A SUGGESTION for obtaining colour-correct photographs of flowers and natural objects without the use of colour screens is made by Mr. J. H. Crabtree in the current number of the *Photographic Monthly*. The method consists in using flashlight powders containing lithium and strontium compounds. It should be instructive to compare results obtained by photographing parrot tulips in this way with photographs taken with a carefully selected colour screen.

IT is at first somewhat surprising to note the great variety of fruits recommended for cultivation in Ceylon in a Circular (vol. iii., No. 14) issued from the Royal Botanic Gardens, as the lists include such European fruits as the pear, cherry, and blackberry, as well as tropical and sub-tropical productions. This is possible owing to the variations in climate at different elevations, and the author, Mr. H. F. Macmillan, arranges his lists according to a vertical scale. A second year's experimental trial of cotton cultivation at Maha-iluppalama forms the subject of another Circular (No. 18).

IN the Kew Bulletin (No. 2) is published the nineteenth series of "Diagnoses Africanæ," containing new species of Hibiscus, Adenium, Strophanthus, and a new Landolphia from Delagoa Bay, also the twelfth series of "Decades Kewenses," including an Aconite from Sikkim and two species of Vitex from Borneo. A collection of marine algæ from the Chatham Islands, from which two new species were obtained, is described by Mr. A. D. Cotton, and Mr. J. M. Hillier contributes some notes on economic products imported into Liverpool. The possibility of growing *Catalpa cordifolia*, allied to the ornamental *Catalpa bignonioides*, for timber in this country is answered in the negative by Mr. W. J. Bean.

THERE is a chance of unintentional misrepresentation or exaggeration when reports of scientific discoveries are presented by non-scientific writers, a notable instance having recently occurred in certain accounts of plant experiments made by Mr L. Burbank. In these circumstances an authentic account by a competent critic was desirable, and such is found in the article contributed by Prof. Hugo de Vries in the *Century Magazine* for this month. While it has happened that owing to the neglect of European records horticultural productions have been incorrectly described as new in America, there is no doubt as to the novelty of many interesting sports collected and developed by Mr Burbank; the Bartlett plum, thornless brambles, and the scarlet Californian poppy attracted Prof. de Vries's notice as he was on the look-out for possible mutations. But in so far as statements have been made that the practical results are opposed to scientific theories, such as the laws of Mendel, Prof. de Vries concludes that Mr Burbank has not studied these theories, being chiefly concerned with the practical value of his varieties.

MR W. E. COLLINGE, head of the department of economic zoology of the University of Birmingham, sends us particulars of a new gooseberry pest identified by him as a result of recent work upon the genus of mites known as Eriophyes, of which *E. ribis* (Nalepa), causing "big bud" on black currants, is perhaps the most familiar example. Mr Collinge has long held the opinion that many other fruit trees would ultimately be found to possess these mites. During the past week he has found a mite of the genus Eriophyes in a number of gooseberry cuttings received from Evesham. The species, which appears to be a new one, is rather longer than *E. ribis*, and a full description of it will be published. It is proposed to name the mite *Eriophyes grossulariae*. The purpose of the present communication is to direct the attention of all gooseberry growers to the new wood of their trees, upon which the buds appear to be dead or dying up. Such should be cut off and immediately destroyed by burning.

THE Phillips Academy, Andover, Mass., which claims to be "the only preparatory school in the world that possesses a fine museum and department of archæology," has issued two Bulletins prepared by Mr W. R. Moorehead, the curator of the Peabody Museum in connection with that institution. The greater part of the first is devoted to an account of the exploration of the Chaco group of Pueblos in New Mexico, from which many specimens of a familiar type were disinterred. More novel and interesting is the description of Flint Ridge, which in the opinion of the author "furnished more material for aboriginal usages than did any given area in the United States. Arrows and knives made of its multicolored chalcedony and chert are found in western New York and far down the Mississippi." The second Bulletin is a study of the "so-called gorgets," a class of perforated articles made of slate, so named because they are generally supposed to be neck ornaments. Various uses have been suggested for these curious objects—that they were ornaments or decorations without religious significance; that they were used as beads, buckles, or buttons; as weights or spindle whorls; for games; or, finally, as amulets. The authors, after a review of these various suggestions, conclude that they were used as neck ornaments with some religious significance, as "bracers," or wrist-protectors in using the bow, and for twine-twisting or netting; but the subject is far from being exhausted, and their origin and use are still obscure. On the whole, these pamphlets are a welcome indication of the importance of anthropological studies in the United States.

THE Transactions of the Institution of Engineers and Shipbuilders in Scotland (vol. l., part iv.) contains a paper by Mr J. G. Johnstone on the stability of submarines. Accidents have happened to several navigable submarine vessels, and as these vessels were of the type known as the diving submarine there has been much discussion regarding the stability of vessels of that special type. The author gives results of investigations into the static stability and the stability of motion of a special case. As the speed of future types is to be made greater, the more important becomes the necessity for such investigations, and it is urged by the author that tank experiments would be of special value.

THE coal-dust problem is discussed by Mr James Ashworth in *Engineering* of March 15. Dust of any sort is a source of danger in every mine that produces fire-damp. The records of various explosions show that the only certain arrestment of a coal-dust explosion occurs when there is an excess of dust, which smothers the flame through lack of air to maintain combustion, and that the most favourable atmosphere to encourage the spread of an explosion is that which contains a maximum percentage of water vapour and a normal quantity of floating coal-dust. Protection against disaster is therefore limited to safe lighting and safe blasting. The watering of dusty roads, which is compulsory in Westphalia, is no deterrent to wholesale devastation.

IN the Journal of the Franklin Institute (vol. clxiii., No. 2) there is an exhaustive article by Mr I. S. Sperry on the manufacture of rolled sterling silver. Within the past twenty-five years this manufacture has undergone a remarkable change. Instead of being confined to the wealthy, sterling silver is now found in very general use, the reason being, not the reduction in the price of silver, but in the cost of manufacture due to the use of rolled sheet metal. Articles which formerly were made from rods are now made by stamping from sheet-metal, with the employment of modern machinery in place of hand labour. The various operations employed in the production of the sheet-metal which is the foundation of the manufacture of modern sterling-silver ware are described and illustrated by Mr Sperry.

THE *Geographical Journal* for March contains a valuable discussion of the existing observations of the heights of the central African lakes and mountains, by Captain T. T. Behrens, R.E. The surfaces of the three principal African lakes having been connected with each other and with the Indian Ocean by a complete set of trigonometrical operations, Captain Behrens compares the results with earlier determinations by hypsometer and barometer, and he also deals with the heights of the principal peaks, which have been connected trigonometrically with more or less accuracy. A list of heights, based on mean sea-level at Mombasa, and carried to Lake Victoria by Uganda railway levels, is compared with means from travellers' observations, and also with values obtained by Dr Kohlschutter, who employs a modification of the usual formula which allows for the influence of local climatic factors. The results seem to indicate that the barometric and hypsometric observations give closer approximations to the truth than is generally supposed.

IN NATURE of February 8, 1906 (vol lxxiii, p 352), a brief account was given of the proceedings of the meeting of the International Meteorological Committee in Innsbruck in September, 1905 The k k Zentralanstalt für Meteorologie und Geodynamik has now published a volume of 154 pages (Vienna W Braumuller, 1906) which contains a full report of these proceedings and much other valuable information Thus, in addition to the reports of several special committees which dealt with cloud classification, earth magnetism, and atmospheric electricity, a valuable series of appendices is given consisting of communications to the commission relating to many different subjects of interest and importance which were considered The text of this volume is in the German language, but a resolution of the commission was passed at the fourth meeting to the effect that both English and French editions should be subsequently published

SINCE the discovery and practical application in Germany of processes for producing "synthetical" indigo, the planters of India have made strenuous efforts to improve their methods of dealing with the natural material In this connection, the report for the year 1906-7 of the work of the Indigo Research Station Sirsiah of the Bihar Planters' Association, which has just been issued presents interesting reading * The report, written by Mr Cyril Bergtheil is divided into three sections, namely, laboratory work, manufacture and agriculture Perhaps the principal point that merits notice is that relating to the discrepancies between the results obtained by a number of different analysts who were entrusted with the examination of the same samples of indigo The same material was analysed at Calcutta, Bradford Manchester, and Berlin, and results were returned by the different analysts varying from 71 per cent to 96 per cent of indigotin The question of the analysis of indigo has recently been the subject of several papers but it is by no means yet decided which is the best and most trustworthy method for the purpose, although Mr Bergtheil confidently recommends the processes he has adopted The question of analysis is one of great importance, and it is clear that no real progress in indigo research can be made until it is satisfactorily settled What appears to be a decided improvement in indigo culture is described in the report with reference to the germination of the seed of the Java plant It would appear that this seed does not usually germinate satisfactorily owing to its possessing a "cuticle" which is impermeable to water To remedy this, it has been found advantageous to soak the seeds for half an hour in concentrated sulphuric acid, and subsequently to wash with water very thoroughly before sowing Good seed treated in this way has been found to germinate to the extent of 100 per cent The report also deals in detail with the work done on the farms established recently to supply seeds of the Java indigo plant

UNDER the title "A Junior Course of Comparative Geography" Messrs G Philip and Son Ltd, have just issued Course A of the "Progressive Course of Comparative Geography," reviewed in the supplement to NATURE of March 14 (p v) The price is 2s 6d net The same publishers have sent us a copy of the seventh edition, revised to date, of their "Handy-volume Atlas of the World," by Mr E G Ravenstein The price of this compact little volume is 3s 6d

IT is clear from the thirty-seventh annual report of the Natural Science Society at Wellington College that the society is in a flourishing condition There is a balance in hand of 113l for which it is to be hoped, some useful scientific purpose will be found The Saturday scientific lectures, which have become a feature of the work of the society, were continued during the Michaelmas and Lent terms The meteorological report of the society is as complete as usual

THE most recently published parts of the Transactions of the Royal Society of Edinburgh are vol xli, part iii, for the session 1904-5 and vol xlv, part i, for the session 1905-6 The papers included in these publications cover those read before the society during a period of about eighteen months The contents are very varied, and amongst subjects of special interest in the first-named part may be mentioned the fresh-water plankton of the Scottish lochs, the structure of the series of line- and band-spectra, the hydrodynamical theory of seiches, and the plant remains in the Scottish peat mosses In the second of the publications are, with others, papers on the varying form of the stomach in man and the anthropoid ape the normal temperature of the monkey and its diurnal variation, and on the effect of changes in the daily routine on this variation the elevation of the boiling points of aqueous solutions of electrolytes and the relationship between concentration and electrolytic conductivity in concentrated aqueous solutions

THE report for 1906 of the Agricultural Research Association for the north-eastern counties of Scotland is devoted almost entirely to an account by Mr T Jamieson of work on the utilisation of nitrogen in air by plants in continuation of the observations described in NATURE a year ago (vol lxxiii, p 531) Mr Jamieson claims that he has obtained further evidence of the absorption of nitrogen from air by plants but the views of scientific experts upon the doctrine he desires to establish were stated in the notice of the previous volume We have not the space available to enter into a detailed statement of Mr Jamieson's position and point out the unsound foundation upon which it rests We must therefore refer our readers to the volume just published for particulars of experiments which Mr Jamieson puts forward as material for a new agricultural science The criticisms of his views expressed at the York meeting of the British Association last year, and also in other places, are dealt with at the end of the present volume

OUR ASTRONOMICAL COLUMN

COMET 1907a (GIACOBINI) —The following elements and ephemeris have been computed for comet 1907a by Herr M Ebell from places observed on March 9, 10, and 11 —

Elements

T = 1907 March 23 5206 Berlin

$$\left.\begin{aligned} \omega &= 319^\circ\ 34'\ 3 \\ \Omega &= 97^\circ\ 40\ 0 \\ i &= 141\ 20\ {}^{\cdot}5 \end{aligned}\right\}\ 1907\ 0$$

log q = 0 31176

Ephemeris 12h (M T Berlin)

1907	α (h m)	δ	Brightness
March 19	6 40	−9 26	0 81
23	6 33	−6 22	0 74
27	6 27	−3 34	0 67

Brightness at time of discovery (mag 11 0) = 1 0

From the above it will be seen that the comet is travelling through the constellation Monoceros towards the northern part of Orion, and that its brightness is decreasing fairly rapidly At present it crosses our meridian at about 6 30 p m, and sets at about 11 30 p m

In No. 10 (March 11) of the *Comptes rendus* M. Giacobini states that the comet is a round nebulous object of 20″ diameter, having an eleventh-magnitude nucleus, and, apparently, a tail in position-angle 180°.

SEARCH-EPHEMERIS FOR COMET 1900 III (GIACOBINI).—In No. 4150 (March 7) of the *Astronomische Nachrichten* Herren Abold and Scharbe publish a search-ephemeris, extending from March 5 to April 2, for comet 1900 III. As the probable time of perihelion passage is very uncertain they give three ephemerides, in which T is taken as May 5, June 8, and July 13 respectively, June 8 being considered the most probable. No perturbations have been taken into account, and as on March 13 the calculated brightness was but 0·4 of that observed on February 15, 1901, it is feared that the hopes of re-discovering this object are but small.

SOLAR OBSERVATIONS AT CATANIA.—In No. 2, vol. xxxvi., of the *Memorie della Società degli Spettroscopisti Italiani* Prof. Riccò publishes the summarised results of the solar observations made at the Catania Observatory during the third and fourth quarters of 1906. There was a marked decrease in the daily frequencies of spots, faculæ, and prominences during the fourth quarter as compared with the third, which, however, showed an increase in the daily frequency of all three phenomena on comparison with the results of the second quarter.

INTENSIFICATION OF "CONTRAST" BY MEANS OF A POLARISCOPE.—Some interesting suggestions concerning the intensification of contrast in astronomical observations by the employment of the polariscope, are made by Dr. Felix Biske in No. 2, vol. xxxvi. (February) of the *Memorie della Società degli Spettroscopisti Italiani*.

Dr. Biske points out that under certain conditions of the atmosphere and positions of the body observed it is possible to polarise the light received so that the ratio of the amount of light from the body to that of the sky is increased, thus rendering the details of the observed object more easily visible. It is suggested that by this means the observation of the corona whilst the sun is not eclipsed may be facilitated, and that comets, the light from which often shows a fair amount of polarisation, may be observed more easily. Similarly the planets Mercury and Venus and the moon may under certain conditions be observed when by the ordinary method this would be very difficult or impossible.

THE MINOR PLANET (588) [1906 T.G.].—In No. 4155 of the *Astronomische Nachrichten*, Dr. Bidschof gives a new set of elements and an ephemeris for the minor planet (588), which it will be remembered is remarkable for its extraordinary aphelion distance, lying an astronomical unit beyond the mean distance of Jupiter. The elements are based upon observations made during 1906, and differ somewhat from those previously published by Dr. Berberich. This interesting object will be unfavourably situated for northern observers for several years, but it is to be hoped that the southern observatories will endeavour to keep it under observation.

The present magnitude of the planet is about 15·0, and it was re-observed by Prof. Wolf in a position in fair accordance with Dr. Bidschof's ephemeris, on January 22.

RESEARCHES IN STELLAR PHOTOMETRY.—Under the title "Researches in Stellar Photometry during the Years 1894 to 1906," made chiefly at the Yerkes Observatory, the Carnegie Institution of Washington has published a beautifully prepared and illustrated volume containing the results of Mr. J. A. Parkhurst's careful and systematic study of twelve variable stars having long periods and faint minima. The observations were carried out first with a 6-inch reflector, then with a 12-inch refractor, and finally with the 40-inch refractor of the Yerkes Observatory. Argelander's method of comparison was employed, and during the later years the comparison stars were carefully standardised with a Pickering equalising wedge-photometer. In addition to the tabulated results giving the individual observations of the variable and of the comparison stars, Mr. Parkhurst gives the complete light-curve for the period of observation, of each variable, and a plate reproduction of a photograph showing the region surrounding each star, the majority of these are on the scale of 1 mm. = 13″·5 (approx.). As an example of an attack on an important phase of the sidereal problem, the volume is almost unique in the wealth of detail it contains and the lavish manner in which the results are presented.

MARSUPIALS OR CREODONTS?

THE vexed question as to the real affinities of the marsupial-like carnivores of the Santa Cruz beds of Patagonia has once more been brought prominently to the front by the appearance of a memoir on their osteology and dentition in the fourth volume of the reports of the Princeton Expedition of 1896–9 to Patagonia. In this memoir the author, Mr. W. J. Sinclair, takes up a very decided position, remarking that these so-called sparassodonts (as represented by Prothylacinus, Borhyæna, Amphiproviverra, &c.) possess a number of characters either peculiar to marsupials or common to that group and only a few other orders. These, it is urged, will convince the reader that sparassodonts are true carnivorous marsupials, not worthy of even separate subordinal rank. Mr. Sinclair goes, however, even farther than this, and considers himself justified in including the Patagonian carnivores in the same family group as the existing Tasmanian pouched wolf or thylacine, which he separates from the Dasyurida under the designation of Thylacinidæ (or Thylacynidæ). It is added that, "although there is sufficient similarity in structure to warrant placing the Patagonian and Tasmanian thylacines in the same family, it must not be inferred that the existing genus is the direct descendant of its extinct South American forerunners. The study of the group has failed to show a closer relationship than probable descent from a common Santa Cruz ancestor. While retaining the fundamental family characters, both lines have diverged, and in some respects the Santa Cruz forms are more advanced than the existing genus."

Among the structural features on which the author relies as evidence of the marsupial nature of the Patagonian fossils are the dental formula, the reduction in the number of successional cheek-teeth, the inflection of the angle of the lower jaw, a number of peculiarities in the conformation of the skull, and the perforation of the transverse process of the seventh cervical vertebra by the arterial canal. On the other hand vacuities in the bony palate and epipubic (marsupial) bones, both of which are characteristic of most existing marsupials, are wanting.

As regards the dental formula of the cheek-teeth, this, in the opinion of Dr. J. L. Wortman (*Amer. Journ. Sci.*, vol. xi., p. 336, 1901) and the present writer, is identical in the sparassodonts, carnivorous marsupials, and creodonts, and is therefore of no importance, except to indicate the mutual relationship of all these three groups. By all zoologists of the present day it is, I believe, admitted that the reduction of the replacing teeth in modern marsupials to a single pair of premolars in each jaw is a secondary feature, so that the presence of a larger number of such teeth in the sparassodonts indicates the more primitive nature of those mammals, and one allying them to creodonts. Some of these sparassodonts differ, however, from all the more typical representatives of the latter group in having four, in place of three, pairs of upper incisor teeth, and thus resemble carnivorous marsupials; but since this feature is likewise regarded by Dr. Wortman (*op. cit.*, p. 335) as of secondary origin, it is no bar to the derivation of sparassodonts from creodonts, while it indicates that the latter are not likely to be the descendants of the former. As the author himself regards the presence of vacuities in the palate and the inflection of the lower jaw as being likewise secondary features in marsupials, all these lines of evidence point to the conclusion that creodonts are the most primitive of the three groups under consideration.

It follows from this, on the author's assumption that the Patagonian carnivores are thylacines, that palatal vacuities have been independently developed in several families of existing marsupials, and a similar argument will hold good with regard to the reduction of the

successional cheek-teeth. Such independent developments seem, however, in the highest degree improbable.

The fact that in the existing thylacine the epipubic bones do not ossify may perhaps be held to indicate that a similar condition obtained in the Miocene sparassodonts, although such a loss is improbable in these early forms, more especially as one of them is considered to have been partially arboreal. Be this as it may, it is quite clear (unless we again admit a series of independent developments) that the sparassodonts cannot be regarded as belonging to a grade of marsupials in which these bones had not yet been evolved, because we find them fully developed in the Oligocene opossums.

The most important argument of all against the marsupial nature of these Patagonian carnivores is, however, one derived from the nature of the enamel of their teeth, which does not appear to have come under the author's notice. According to the observations of Mr. C. S. Tomes (Proc. Zool. Soc. London, 1906, p. 45) the enamel of the sparassodont teeth is histologically identical with that of creodonts and modern carnivores, and quite unlike that of all marsupials.

Seeing, then, that sparassodonts, which are later in age than certain undoubted marsupials, differ from existing carnivorous marsupials as a whole in the minute structure of their dental enamel, by the lack of epipubic bones, the absence of unossified spaces in the floor of the skull, and apparently by the larger number of successional premolars, it seems improbable that they are really members of that group. On the other hand, they resemble creodonts in their complete palates, in the absence of epipubic bones, and to a great degree as regards the replacement of the cheek-teeth, while it is highly probable that many of the cranial characters referred to as being marsupial may really be primitive ones. The one essentially marsupial feature is the presence, in some cases, of four pairs of upper incisors.

On the whole, therefore, it seems advisable to regard the Patagonian carnivores as creodonts showing a tendency (it may or may not be parallelism) towards the marsupial type. That creodonts, sparassodonts, and carnivorous marsupials are, however, related groups, and that the former are not improbably the oldest and most primitive of all known mammals (perhaps directly descended in "Gondwanaland" from anomodont reptiles), appears almost certain. And it may further be suggested that these early creodonts have developed in one direction towards the sparassodont type, in a second towards the carnivorous marsupials, while in a third line they have developed into the modern Carnivora. Beyond this it seems at present impossible to go.

It should be added that the present writer was at one time of opinion that sparassodonts were marsupials.

R. L.

THE GODS OF HEALING OF THE EGYPTIANS AND GREEKS.

DR. R. CATON recently delivered a short course of lectures on the above subject in connection with the Institute of Archæology at the University of Liverpool. After referring to the works on medicine written by Athosis, the son of Menes, and also by the Pharaohs Usaphais and Semti in very early times, he described briefly the cults of Isis, Serapis, Thoth, and I-em-hotep, and gave a short account of the temples in which the work of healing took place. Of these, quite the most important was the temple of I-em-hotep at Memphis. All these shrines of healing are destroyed, excepting the small temple of I-em-hotep on the island of Philæ. Dr. Caton referred to the large number of medicinal agents used by the Egyptians, and to the practice of incubation or temple sleep. In the temples of Isis and Serapis, and probably in the more important shrines of I-em-hotep, the sick slept in or adjacent to the temples in the belief that the god would manifest himself to them or speak to them in dream or vision, and suggest the method of cure. Such dreams or visions were interpreted by the priest, and the treatment adopted was supposed to be founded in accordance with them. Sometimes no dream was vouchsafed, or no interpretation could be drawn from it bearing on the disease; in that case the priest did the dreaming. The priests of I-em-hotep had also to do with the embalming of the body, and, partly through this, they acquired a considerable knowledge of anatomy, and learned certain facts regarding the circulation of the blood. Some of the medical papyri contain remarkable details as to the blood-vessels and the movement of the blood; probably the Greeks obtained from them all the knowledge they possessed on this subject.

In Greece and Magna Græcia various gods and demi-gods were supposed to possess medical powers. Men Karou at Laodicea was a health god much in vogue in Asia Minor, and a large medical school was associated with his temple.

Apollo, Amynos, Asklepios, Hygeia, Amphiaraus, Trophonios, Aphrodite, and the Chthonic deities Pluto, Demeter, Persephone, and others of lesser importance were eminent for their health-giving efficacy in Greece. Of these the cult of Asklepios was by far the most important. At numerous splendid temples, rich with the finest products of Greek art, the worship of the god and the cure of the sick were carried on for centuries.

Epidaurus was perhaps the most important of these shrines; it was a centre from which the cult was disseminated through other parts of Greece and the colonies. Trained priests, and also the sacred serpents, which were believed to be the incarnation of the god, were sent thence to carry on the work of healing in such places as Athens, Corinth, Delphi, Pergamon, Cnidos, Rhodes, Cos, and many other cities.

In all incubation was the initial step and the guide as to treatment. Probably the people would have had no confidence in the methods used but for the belief that the god himself had suggested them; even the priests themselves may in part have been believers. Many of the priests were physicians, who in the course of ages compiled much valuable information; they possessed useful methods of treatment in regard to rest, to diet, to the remedial use of exercise and of baths, and medicines. The ritual was beautiful and impressive, and their practice seems to have been humane in all respects except one. The god and his priests must have no dealings with death or with birth. If either were impending, the unhappy patient was at once expelled from the holy precinct. Not until the time of the Antonines were the special "houses of Birth and of Death" provided external to the precinct for these two classes of sufferers.

At Cos the influence of Hippocrates seems to have been directed always towards the effacement of superstition and the founding of medicine on truth and fact alone. His influence seems to have had no effect as regards the practice of incubation, for it continued through Pagan and into Christian times.

As the East was Christianised the cult of Asklepios was the last to disappear, but the healing went on in the same manner (excepting that the sacred serpents seem to have vanished). The Panagia, or a Christian saint, took the place of Asklepios, and incubation went on unchanged. The practice spread over large parts of Europe, and was even to be found in England during the Dark Ages.

It still exists on many of the islands and on some of the shores of the eastern Mediterranean. Details of the ancient and modern practice of incubation are to be found in the writings of Dr. Rouse and Miss Hamilton, who have both devoted close attention to this curious usage.

An interesting feature of the life of these ancient health resorts was the provision made for the entertainment and amusement of the sick visitors. A great open-air theatre was always at their disposal, where the works of the Greek dramatists would wile away many an hour of weariness and languor.

In later times an Odeon, or music-hall, was sometimes provided. The races of the stadium and the exercises of the gymnasium and palæstra would be good for many of the youthful convalescents to take part in, and amusing for others to witness. The health temples were usually placed in elevated situations, where pure mountain breezes would invigorate the visitant, and pure, fresh water was

abundant. Beautiful country scenery, as well as masterpieces of architecture and art of other kinds in the precinct, would attract his attention, awaken his interest, and tend to prevent him dwelling too much in thought on his own ailments. There can be little doubt that the sick were in general much benefited by their residence at the Asklepieia of ancient Greece.

THE SNOW-PEAKS OF RUWENZORI.

THE paper read by the Duke of the Abruzzi at the special meeting of the Royal Geographical Society on January 12, of which a short report was given in NATURE for January 17 (p. 282), has been printed in full

The paper as printed supplies information as to the basis for the determination of the heights of the snow-peaks, fourteen of which were climbed by the Duke. With one exception, they all depend on observations with the mercurial barometer referred to Bujongolo as a lower station, which again was linked with Fort Portal, and through this with Entebbe, by barometer readings as nearly simultaneous as possible. Some of the heights above Bujongolo were also fixed by Captain Cagni by vertical angles, the results agreeing closely with those of the barometer observations. The Duke's figures are mostly about 100 feet to 200 feet in excess of those derived from Captain Behrens's triangulation, and it is possible that when the altitude of Fort Portal above the Victoria lake has been

The Highest Peaks of Ruwenzori.

in the February number of the *Geographical Journal*, accompanied by a small selection of Signor Sella's striking photographs. One of these, showing the highest summits of the range, we are enabled to reproduce herewith by the courtesy of the editor of that journal. The twin peaks in the background on the left are the culminating points of the whole range, named by the Duke after the queens of Italy and England. They belong to the group of peaks named by him Mount Stanley, while the remaining summits shown in the photograph form together the group to which the name Mount Baker is applied, the highest point of which is King Edward Peak (the most central in the picture). As is well shown, the two *massifs* (like the whole six which constitute the snowy portion of the range) are separated by a comparatively deep depression, to which the name Scott Elliot Pass has been given by the Duke.

fixed trigonometrically, a small correction will have to be applied throughout. The general accordance in the heights of the six separate *massifs* is somewhat striking, none falling below 15,000 feet, while the highest point of all is only 16,816 feet. None of the peaks offers any serious difficulties to the climber, for the Duke says that the obstacles met with during the ascent of the Queen Margherita peak could have been avoided by another route.

The Duke's conclusions as to the geological history of the range were summarised in our former article, but it may be added here that attention is directed to the probable existence of internal fractures traversing the whole range in a generally north-south direction, which would account for the separation of the several groups of summits. The general hydrographic system can be grasped from the

rough sketch accompanying our former report, which shows how the Bujuku derives its supplies from a much larger part of the snowy area than does the stream hitherto considered to be the upper course of the Mobuku. The Duke was not able to define so clearly the drainage on the side of the Semliki, but he says that the streams flowing west from the four main passes leading in that direction all unite to form the Butagu, the valley of which has been the usual line of approach to the snows on this side. In the Ice age the whole of the valleys of the Bujuku, Mobuku, and Mahoma (south of, and parallel to, the Mobuku) were filled with glaciers of the first order, which must have united and descended the Mobuku valley for some distance. Similarly, glaciers descending from the three southernmost of the groups must have united to form a great westward-flowing ice-stream. At present the lowest point reached by a glacier (that which feeds the Mobuku) is 13,682 feet. The permanent snows are included in a circle ten miles in diameter.

It should be mentioned that the Royal Geographical Society proposes to apply the Duke's name to the most southerly of the snowy *massifs*, instead of that of Thomson, who himself never saw Ruwenzori, important as his work was for the general opening up of this part of East Africa.

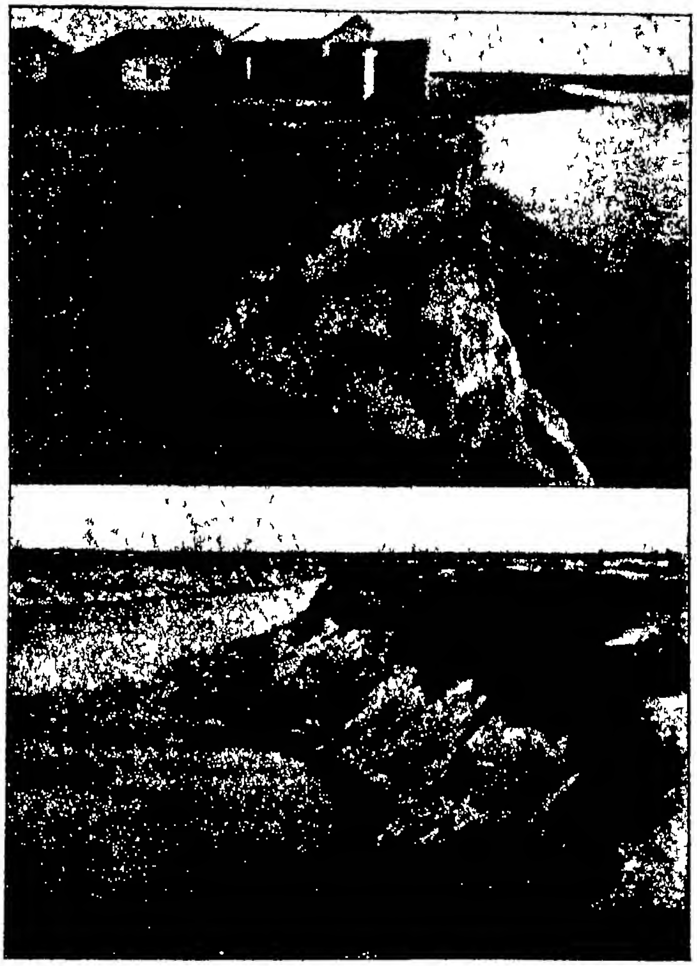
MAN AND SUPERMAN.

MR. ARTHUR J. DAVIS, of the U.S. Reclamation Service, describes in the *National Geographic Magazine* for January the startling changes that are now taking place in the region north of the Gulf of California. For 150 miles from the apex of the gulf, an area of delta and alluvium and old sea-bottom extends to the north-west between the mountains. The upper part of this basin forms the Imperial Valley, and lies in the territory of the United States. Below the Mexican frontier, the Colorado River, emerging from the hills, has built up a huge alluvial barrier above the level of the land to the north of it. This in its growth cut off the head of the ancient gulf, and led to the gradual disappearance of the water by evaporation.

The Imperial Valley thus came into existence, with part of its floor 300 feet below the level of the adjacent sea, and a variable lake without an outlet, the Salton Sink, at its northern end. From time to time the Colorado River, in seasons of flood, has diverted itself from the elevated delta into the Salton Sink, and the lake has grown in consequence. At other times it has banked itself out of this region, has flowed again into the Gulf of California, and has left its temporary northward-running channels, the Alamo and New Rivers, practically dry and sand-filled.

The ease with which the northern lowland could be irrigated led to the formation of a canal about seven years ago. Its mouth, however, became silted up, and a spot was then selected above a steeper slope, where the velocity of the water leaving the Colorado was greater and more effective. In May, 1905, however, the first serious flood-waters deepened this new channel, and supplied far more water northward than was required. The "Salton Sea" rose rapidly, and the Southern Pacific Railroad along its margin was equally rapidly moved to higher ground. Striking alterations occurred in the old valley-floors as they were invaded, and the cataract of the New River, cutting its way back to the frontier town of Calexico, flowed there in a channel 45 feet below the level of the farm-lands. The peril became so great in 1906 that a huge dam was constructed on the delta, in order to compel the Colorado River to return to its former route into the Gulf of California. Mr. Davis's account of this titanic struggle—the printer makes him speak of "herculanean efforts"—forms very interesting reading. The dam having been completed last November, it was estimated that the enlarged "Salton Sea" would dry up in about twelve years; but in December the water of the Colorado worked its way round the dam, and resumed its rush into the Imperial Valley.

The great cataract in the New River was in January eating its way backward, that is to say southward, at the rate of a mile in three days, with a width of some 1700 yards and a fall of 100 feet. The farms in the Imperial Valley are unable to avail themselves of the water so copiously



Upper figure.—Partial destruction of the town of Mexicala, Mexico, by the New River. *Lower figure.*—The New River cutting into the farm lands near Imperial, California, forming banks 70 feet in height, which are constantly falling in.

supplied, since it lies below their level; a great inland sea is arising and dispossessing the railroad and the people whom it serves; and the probability of the diversion of the whole Colorado River northward threatens to deprive of water the settlers in Arizona and Mexico from the Grand Cañon down to the Gulf of California. It needs the philosophic spirit of a Lyell to regard physiographic changes of such magnitude with admiration rather than dismay.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—Lord Curzon was elected Chancellor of the University on Thursday, March 14. The votes recorded were:—Lord Curzon, 1101; Lord Rosebery, 440. There are 6576 members of Convocation, so that about one-quarter of them came to Oxford to vote. Lord Curzon was a commoner of Balliol, afterwards a fellow of All Souls, and he gained the Lothian and Arnold prizes. He received an hon. D.C.L. in 1904 on the occasion of the late Chancellor's installation.

The statute brought forward in Congregation on May 12 to provide an official residence for the Savilian professor of astronomy adjoining the observatory in the parks was lost by 55 votes to 156. In the course of the debate on the proposal, the Warden of All Souls', one of the Radcliffe trustees, stated that the trustees would welcome a scheme for the cooperation of the University and Radcliffe Observatories.

CAMBRIDGE.—A lecture will be given by Sir Frederick Ely on "The Practical Side of Famines in India" on Wednesday, April 24, at 5.30 p.m., in the museum of archæology. The lecture will be open to members of the University and others who are interested in the Indian Empire.

THE King of Spain has, *La Nature* reports, created a chair of automobilism at l'École des Arts et Sciences at Madrid. The professor will be expected to give all the practical and theoretical instruction young chauffeurs require.

A PARAGRAPH referring to the Indian Institute of Science appeared in the *Pioneer Mail* a few weeks ago, and was printed in an abridged form in these columns. Dr. Morris W. Travers, F.R.S., director of the institute, writes to say that he has had numerous applications for admission to the institute, so the statement in the *Pioneer Mail* that it will be difficult to obtain students is scarcely correct. As to the standard required for degrees in Indian universities, Dr. Travers remarks:—"It is true that I have expressed disappointment at the standard of the work required for degrees in the Indian universities, and am of the opinion that the practical teaching is quite inadequate. I have met only one research student, and have heard of one other."

A CONFERENCE on the teaching of hygiene and temperance in the universities and schools of the British Empire will be held in London on St. George's Day, April 23. The conference is convened by a committee formed to stimulate general interest in the scientific teaching of hygiene and temperance as an integral basis of national education, and to bring before the country during the visit of the Colonial Premiers information as to what is being done in various parts of the Empire. Among the members of the committee are Sir Lauder Brunton, Sir Thomas Barlow, Sir Victor Horsley, Mr. Mayo Robson, Dr. Claude Taylor, and Prof. Sims Woodhead. Further information and tickets of admission to the conference may be obtained from the honorary organising secretary, Miss St. John Wileman, 11 Chandos Street, Cavendish Square.

A RECENT article in the *Pioneer* of Allahabad deals with the work and usefulness of the Thomason Civil Engineering College at Roorkee, United Provinces, which is the leading engineering college in India. In 1891 the college was transferred from the Public Works Department to the Education Department, affiliated to Allahabad University, and its educational staff strengthened on the purely scientific side. The Government of the United Provinces has decided again to extend the college, and the improvements will call for an expenditure of three and a half lakhs. The important part which a properly organised technical institution may play in industrial development should be borne in mind when the extensions or changes at Roorkee are under consideration. Higher technical education is, of course, costly to provide, but the development of technical institutions on broad scientific lines is an urgent need in India, and in endeavouring to meet it the close relation between pure and applied science must be remembered. It is to be hoped that further developments at Roorkee will continue along the lines proved to be successful at home, and result in a strengthening of Thomason College and other Indian educational institutions.

THE council of King's College, London, with the assent of its court, has concluded an agreement by which the departments of the college dealing with arts, laws, science, engineering, and medicine (preliminary and intermediate studies) are to be incorporated in the University of London on terms similar to those recently adopted in the case of University College. An indispensable condition to the incorporation of the college is the raising of a sum of 125,000*l*. Of the sum in question 22,000*l*. is needed to pay off the debt on the college, 37,000*l*. to pay off the debt on King's College School, which will thereafter be placed under separate government, and 66,000*l*. to form an endowment fund and enable the college to occupy the whole of its premises. An appeal is being made to the public to provide this amount. The appeal has been endorsed by the Senate of the University of London, and already encouraging promises of support have been given. The Goldsmiths' Company and the Clothworkers' Company have each given 5000*l*. In addition to the 125,000*l*., the council asks for 20,000*l*. for the endowment of the theological department. Donations may be given generally to the fund in aid of the incorporation of King's College in the University of London, or else to any of the specific objects above mentioned. No sum will be devoted to the theological department unless specially given for that purpose.

THE eleventh annual distribution of prizes and certificates to the students of the day college and evening classes of the South-Western Polytechnic, Chelsea, took place on March 15. In the unavoidable absence of the Lord Chief Justice (Lord Alverstone), Sir Owen Roberts presented the awards. The principal, in the course of his report on the session 1905–6, spoke of the satisfactory character of the work carried on, and directed special attention to the large increase of student entries in the natural science department. He referred to the need which existed for more continuous work on the part of the students, and instanced the fact that during last session the average hours worked by each adult student in the day classes was only 234, or the equivalent of eight weeks' full work out of thirty-six weeks possible. The institute's record in respect of examination honours and degrees had been well maintained. The equipment of the various departments had been largely increased, and was being rapidly brought up to the standard of modern requirements. Sir Owen Roberts, in addressing the students, expressed satisfaction at the close relationship between the institute and London University. He urged the desirability in the case of persons actively engaged of some study to take them outside their ordinary occupation, and which was provided by the scheme of work carried out in the institute.

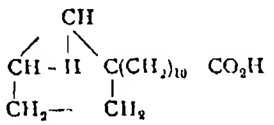
THE inaugural lecture of the new Sibthorpian professor in the University of Oxford develops a plea for the reconsideration of agriculture by the University. Although Dr. Somerville has been appointed professor of rural economy, his present duty is to lecture upon forest botany, and he makes it clear that this is not his own interpretation of the term "rural economy." Those who read this lecture will agree that a good case is made out for agriculture as a university subject. Dr. Somerville, as becomes a new professor, contents himself with making suggestions. Outsiders interested in the development of agriculture will probably wish that it had been possible to make demands, for it is surely time that Oxford was doing something for agriculture. The first page of this lecture tells us that Sibthorp endowed the chair in 1796; we read further that for a century it was the only university chair of its kind in England; but when, after following Dr. Somerville's account of the progress of agricultural education during this century, we pause and ask what Oxford's share has been, we find that it has been practically *nil*. Occasional lectures have been given, and once or twice attempts have been made to introduce an agricultural course, but the University has rejected the schemes of the advocates of agriculture, and now, 110

years after Sibthorp's foundation, Oxford's new professor is pointing out that while sixteen of the twenty-five university graduates recently appointed to the Indian Agricultural Department have been trained in Cambridge and Edinburgh, "Oxford has not supplied a single candidate for these Imperial posts." We should like to urge reconsideration of the subject on other grounds. Agriculture needs the support of the English universities, and in the past it has suffered through their neglect. By her influence on the young landowners who pass through her colleges Oxford might make her teaching felt on many an English estate.

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, March 7.—Prof. R. Meldola, F.R.S., president, in the chair.—The constitution of chaulmoogric and hydnocarpic acids: M. **Barrowcliff** and F. B. **Power**. A study of the oxidation products of chaulmoogric acid leads to the conclusion that it exists in a state of tautomerism between 1-α-carboxy-n-dodecyl-Δ^4-*cyclo*pentene and 1-α-carboxy-n-dodecyl-1:4-*bicyclo*pentane. Hydnocarpic acid, $C_{16}H_{28}O_2$, is a homologue of chaulmoogric acid. Its constitution may accordingly be represented by the following formula:—



—Hydrolysis of amygdalin by acids: R. J. **Caldwell** and S. L. **Courtauld**. The authors have studied the action of acids in comparison with that of enzymes on this "bioside," and the results show that though amygdalin is ultimately resolved by acids into hydrogen cyanide, benzaldehyde, and two molecular proportions of glucose, the separation of the glucose is effected in two stages. By carefully hydrolysing amygdalin by means of a normal solution of hydrogen chloride at 60° the authors have prepared mandelonitrile glucoside.—Mandelonitrile glucosides. Prulaurasin: R. J. **Caldwell** and S. L. **Courtauld**. Fischer's glucoside bears the same relation to prulaurasin as amygdalin bears to the isoamygdalin described by Dakin, which is to be regarded as the derivative of inactive mandelonitrile, amygdalin and Fischer's glucoside being derived from *l*-mandelonitrile. Sambunigrin must be regarded as the β-glucoside of *d*-mandelonitrile.—The hydrolysis of amygdalin by emulsin: S. J. M. **Auld**. The hydrolysis of amygdalin by emulsin may proceed in three ways depending on the mode of attachment of the emulsin. The experiments so far carried out by the author indicate that benzaldehydecyanohydrin and the αβ-disaccharide are formed, and the latter then resolves into two molecules of dextrose.—Electrolytic reduction, part iii.: H. D. **Law**. The products of electrolytic reduction of the aromatic aldehydes in alkaline solution are compounds of the hydrobenzoin type, but this reaction is completely altered when a methyl group is substituted in the *ortho* or *meta* position of the benzene nucleus. Compounds of a resinous nature are obtained in the latter case.—New cerium salts: G. T. **Morgan** and E. **Cahen**. The aromatic sulphonates of this element are usually soluble crystalline compounds resembling the thorium sulphonates previously described by one of the authors.—Volume changes which accompany transformations in the system $Na_2S_2O_3 \cdot 5H_2O$: H. M. **Dawson** and C. G. **Jackson**. The changes which take place in the system $Na_2S_2O_3 \cdot 5H_2O$ when subjected to certain temperature variations, have been investigated by the dilatometric method.—Depression of the freezing point of aqueous solutions of hydrogen peroxide by potassium persulphate and other compounds: T. S. **Price**. Potassium persulphate causes a less molecular depression of the freezing point of aqueous solutions of hydrogen peroxide than it does of water, and the conclusion is drawn that an unstable compound is formed in solution.—The formation and reactions of imino-compounds, part iii.: the formation of 1:3-naphthylenediamine and its derivatives from o-toluonitrile: J. F. J. **Atkinson**, H. **Ingham**, and J. F. **Thorpe**.—The action of ethylene dibromide and of propylene dibromide on the disodium derivative of diacetylacetone: A. W. **Bain**.

Mathematical Society, March 14.—Sir W. D. Niven, vice-president, in the chair.—Mr. G. W. **Evans-Cross** exhibited his calculating machine, the myriometer. The instrument has several different forms, which are all, in principle, modifications of the slide-rule. In the form in which the instrument can be used for multiplication, the rule consists of a number, equal to that of the digits in one factor, of slips placed diagonally in a frame, and the slide carries as many cursors as there are digits in the other factor. The instrument will give exact results for numbers of six or eight digits. In other forms the instrument can be used for various calculations relating to commerce, such as the reduction of the interest on a stated sum from one percentage to another. In another form slides can be set so as to give the calendar of any year, B.C. or A.D., and all the new moons of the year.—Invariants of the general quadratic form modulo 2: Prof. L. E. **Dickson**. Complete sets of independent invariants, and also of linearly independent invariants, are obtained for quadratic forms of not more than five variables in the field of order two, and those invariants of quadratic forms of six variables which can be deduced are also given. It is shown that the complete classification of quadratic forms can be accomplished by means of invariant functions.—Linear partial differential equations of the first order: J. **Brill**. The paper is occupied with a general review of the theory, and an endeavour to ascertain the relations of exceptional solutions to the solutions of classified types.—The reduction of the factorisation of binary septans and octans to the solution of an indeterminate equation: Dr. F. **Stuart**.—An informal communication on the representation of functions by means of series of a special type was made by Prof. A. E. H. **Love**.

PARIS

Academy of Sciences, March 11.—M. Henri Becquerel in the chair.—Some details of the spectroheliograph: H. **Deslandres**. Remarks on a recent paper by M. Millochau in the *Comptes rendus*. Many of the details described by M. Millochau as new have been used by the author for years, and further details of working are now added.—A new contribution to the study of the stinging flies of intertropical Africa: A. **Laveran**. A detailed account of the various species found in the districts of Senegal, Mauritania, the Upper Senegal and Niger, French Guinea, the Congo Free State, and Mozambique.—The direct dehydration of dimethyl-isopropyl carbinol: Louis **Henry**. The dehydration of this alcohol might be expected to give rise to pure tetramethylethylene, and it was with this object in view that the experiments were carried out. The reaction proved to be not quite so simple, the fractionation of the hydrocarbons obtained by the action of acetic anhydride upon the alcohol giving tetramethylethylene and methyl-isopropylethylene, the former hydrocarbon being about three-quarters of the total product.—Some new results obtained in the detection and estimation of methane: Nestor **Gréhant**. An improvement of an apparatus previously described.—The perpetual secretary announced the death of François Joseph Herrgott, correspondant for the section of medicine and surgery.—A new comet: M. **Giacobini** (see p. 498).—The elastic deformations which leave invariable the lengths of a triple infinity of right lines: G. **Kœnigs**.—Waves of shock and combustion. The stability of the explosive wave: MM. **Crussard** and **Jouguet**. It is assumed that the combustion is incomplete in the wave, but is completed behind adiabatically and reversibly according to the law of dissociation, and the consequences of this assumption are worked out.—The conditions of formation of electrified centres of feeble mobility in gases: Maurice **de Broglie**. Experiments on carbon monoxide flames and flames containing hydrogen lead to the conclusion that the presence of centres of feeble mobility in the gases issuing from flames appears to be related to the production in the flame of solid or liquid products, or to the presence of some centres previously existing in the normal state in the atmo-

spheric air.—A contribution to the study of the latent photographic image: Eug. **Demole**. Some experiments on the reversal of the image caused by the presence of a feeble oxidising agent, such as potassium ferricyanide. The author puts forward a theory of the process based on the formation of a hypothetical silver hypobromite.—An exact method of separating ammonia and methylamine: Maurice **François**. The method is based on the fact that ammonia is readily absorbed by yellow oxide of mercury, whilst methylamine is not acted upon by this reagent.—The constitution of the azo derivatives of ethyl benzoylacetate: A. **Wahl**.—The β-chlorethyl and vinyl ketones: E. E. **Blaise** and M. **Maire**.—The influence of manganese salts on alcoholic fermentation: E. **Kayser** and H. **Marchand**. The effect of adding manganese salts to a fermentable liquid is to increase the amount of sugar fermented, the yields of alcohol, glycerine, and volatile acid all being greater.—A new glucoside, hydrolysable by emulsin, extracted from the seeds of a Strychnos from Madagascar: Em. **Bourquelot** and H. **Hérissey**. The name bakankosine is given to the new glucoside, and its method of preparation, properties and products of hydrolysis are given in detail.—The cytological peculiarities of the development of the mother cells of the pollen of *Nymphaea alba* and *Nuphar luteum*: W. **Lubimenko** and A. **Maige.**—The ecological characters of the vegetation in the eastern region of the Kabyle and Djurjura: G. **Lapie.** The forest vegetation in this region presents well-characterised zones standing clearly in relation with the climatological, topographical, and edaphical conditions.—A phenomenon of plant pseudomorphosis analogous to the pseudomorphosis of minerals: N. **Jacobesco.**—A spiky formation characteristic of the last dorsal vertebra in man: R. **Robinson.**—The tectonic north of Meurthe-et-Moselle: René **Nicklès** and Henri **Joly.**

CALCUTTA

Asiatic Society of Bengal, February 6.—The exact determination of the fastness of the more common indigenous dyes of Bengal and comparison with typical synthetic dyestuffs, part i., dyeing on cotton: E. R. **Watson**. The author gives a summary of the available evidence as to the fastness of the indigenous Bengal dyes, and points out that this evidence is wanting in precision and is in many cases self-contradictory. The author has prepared samples of cotton dyed with the more common Bengal dyes, so far as possible according to native methods, and has tested the fastness of these dyeings (1) to light, (2) to washing with soap, (3) to alkalis, (4) to dilute acids such as perspiration, testing at the same time by the same methods a representative collection of dyeings with synthetic materials. Tables are given in which the fastness of each dyeing under each condition is expressed quantitatively. The dyestuffs turmeric, safflower, *palas* (*Butea frondosa*), *latkan* (*Bixa Orellana*), red sandal (*Pterocarpus santalinus*), and *padauk* (*Pterocarpus dalbergioides*) are of very inferior fastness. *Manjista* (*Rubia cordifolia*), catechu (*Acacia catechu*) and *bakam* (*Caesalpinia Sappan*) compare favourably with the great majority of synthetic dyes.—*Breynia vredenburgi*, an undescribed echinoid from the Indian Ocean: Major A. R. S. **Anderson**. The genus Breynia was founded in 1847 by Desor for Spatangidæ characterised by the simultaneous presence of the three kinds of fascioles, internal, peripetalous and subanal. Only one living species had hitherto been described, *Breynia australasiae*, from the Pacific Ocean. Another species was discovered by Major Anderson at Port-Blair in the Andamans and has been named *Breynia vredenburgi*. The original specimen is now in the Indian Museum.—Note on the common raven (*Corvus corax*): Lieut.-Col. D. C. **Phillott.**

ULTRAMICROSCOPES

Les Ultramicroscopes Les Objets ultramicroscopiques By MM A Cotton and H Mouton Pp 232 (Paris Masson et Cie, 1906)

THE magnitude of an object which can be rendered visible by the ordinary use of the microscope has a lower limit which is well understood and can be succinctly expressed It depends not merely upon the construction of the instrument, but also upon the character of the light employed and upon the liquid used for immersion The instrument should possess a large numerical aperture, which is again increased by immersion in the ratio represented by the index of the immersing liquid, the result being the scientific expression for the power of the instrument, with a given magnifying power, to resolve close lines or points As regards the light itself, the limit of resolution is proportional to the wave-length, so that shorter wave-length implies greater power of resolution When special light is not selected for employment, the mean value of the wave-length is 0 55 μ, where μ signifies 0 001 of a millimetre

Taking full advantage of these principles and of the high index, 1 66, of monobromonaphthalin as an immersion liquid, it may be said that the smallest visible objects have a magnitude not less than 0 17 μ Bodies smaller than this are called ultramicroscopic Some plan other than the usual microscope method must be adopted in order to make their existence appreciable, and it is upon this subject that MM Cotton and Mouton have written the very valuable and learned book before us In it will be found accounts, not merely of their own work, which is far-reaching and in practical points highly ingenious, but also of that of other investigators in the same field

There are two methods at present in existence, which may be called respectively that of ultra-violet light and that of diffraction in a dark field The first method aims at taking advantage of the short length of ultra-violet wave-lengths The sources of light are electric sparks formed between wires, which may be of magnesium, producing wave-lengths of 0 280 μ, or of cadmium, producing those of 0 275 μ, the former being more intense, the latter more homogeneous Such waves produce no effect upon the eye, though much upon fluorescent screens and photographic plates But they are readily absorbed by glass Hence the media (excepting air and immersing liquids) through which they pass on their way to the fluorescent screen or photographic plate, as the case may be, must be of quartz, and those above the stage of the microscope must, to avoid effects of double refraction, be of fused quartz Thus the whole apparatus is highly specialised On the other hand, the rays employed being homogeneous, there is no chromatic aberration to be considered in the design of the lenses.

The image formed by the objective is again magnified by the ocular, employed in such a way as to form a second real image at the place where finally is placed the fluorescent screen or photographic plate With such an apparatus the limit of magnitude of the objects detected would be reduced to 0 09 μ

The second and more recent method of detecting ultramicroscopic bodies is to employ their power of diffracting the light which falls upon them They thus become mere point sources of light, but diffraction discs are formed upon the retina of the eye, as in the case of stars the dimensions of which are far too small to subtend an appreciable angle, even with the most powerful telescopic aid

In the microscope, then, the illuminated ultramicroscopic object merely appears as a star of light The form of the object is entirely unobserved, its presence only being appreciable when certain conditions are fulfilled These are that the illumination shall be intense, that the field shall be profoundly dark, and that the objects themselves shall be sufficiently sparsely distributed in the field It is advantageous, too, to employ those rays which make as small an angle with the illuminating beam as is consistent with other conditions

To ensure the dark field it is strictly necessary that *none of the illuminating light shall*, except by diffraction, pass into the objective

First, we have described in detail the apparatus of Siedentopf and Zsigmondy In this the light from a narrow slit is focussed in such a way as to pass horizontally through the transparent medium under observation, forming a much diminished image of the slit exactly in the point of view of the microscope In this image the width of the tape of light producing it corresponds to the length of the slit, and the depth to the width of the slit The depth of the illuminated region thus becomes, with a knowledge of the diminishing power of the train of lenses strictly calculable, this being of importance in estimating the number of particles rendered visible in a cubic millimetre No part of the illuminating beam can, except when diffracted by small particles, pass into the objective The mean direction of the rays which do so pass will be at right angles to the illuminating beam The plan has the great advantage that an immersing liquid can be employed in the examination of solids, such as glasses tinted with metals, or of liquids beneath a covering glass The adjustments must, however, be extremely nice, and require that the whole apparatus should be mounted upon one bank

The authors have devised a simpler plan of illuminating the subsurface regions of a medium by taking care that incidence with the surface shall be at an angle exceeding the critical angle To this end a small but intense beam of light is brought from a small arc downwards at an angle of 51° to the vertical This passes at vertical incidence through the bevelled edge of a glass plate about 1 cm thick upon the microscope stage It is then totally reflected upwards by the lower surface towards the upper one

Upon this is placed the microscope slide, with an intervening drop of cedar-wood oil, so that total reflection does not occur again until the upper surface of the cover glass is reached, when the ray is again sent downwards and passes away through another bevelled edge. It will be understood that the preparation does not contain air. On this plan no immersion liquid can be employed in the usual place between the cover glass and the objective, but, on the other hand, the rays diffracted by small particles come off from the main beam at angles considerably smaller than a right angle.

Several chapters of the book are devoted to the investigations which have been or can be carried out by these ultramicroscopes, of high interest to many. As examples, we may cite the distribution of silver, gold, and other metal particles in the coloured glasses containing them, and in the hydrosols of such metals, the Brownian movements of ultramicroscopic bodies in colloids, and the translation of such bodies by electric current. Especially interesting is the description given of the motions of silver particles in the hydrosol of that metal prepared by the Bredig process of forming a submerged electric arc between silver wires. The particles, below certain dimensions, remain in stable suspension. They are quite ultramicroscopic, but still are capable of diffracting light. When an electric current is passed through the liquid contained in a layer, not too thin, between top and bottom planes of glass, quartz, mica, &c., the microscope being focussed at the middle of the layer, at a point about equally removed from either electrode, the points of light seen move equably in a direction from the kathode to the anode, the speed being proportional to the potential gradient. For one volt per centimetre the speed is about 3·78 μ per second. Above and below this central region, *i.e.* in beds adjoining the top and bottom boundaries, the motion is in the opposite direction, somewhat slower and less equable, and variable with the size of the particles.

If the boundary surfaces are of glass, these inverse beds are each about 25 μ in depth, and if the thickness of the whole layer is diminished until it is only 50 μ, it is these inverse beds which survive, the central one being gradually extinguished. The motion will then be entirely from anode to kathode.

The material of the boundaries affects the depth of the inverse beds, which with quartz is rather less than 25 μ, and seems to disappear with gypsum. Mica has much the same effect as glass in this particular.

The particles have such exceedingly small mass that their ultimate velocities in the central region are acquired instantaneously, and if the electrodes are connected with an alternating source of electromotive force, the points of light move backwards and forwards in harmony with the stress through a distance proportional to its mean value and to the period, the constant being sensibly consistent with the speed under uniform stress quoted above. If a three-phase machine is connected with three electrodes, the particles describe closed curves.

THOMAS H. BLAKESLEY.

ANCIENT AND MODERN SHIPS.

Ancient and Modern Ships. By Sir George C. V. Holmes, K.C.V.O. Part i., Wooden Sailing-ships. Pp. xv+168. Part ii., The Era of Steam, Iron, and Steel. Pp. xii+219. (London: Printed for His Majesty's Stationery Office by Wyman and Sons, 1906.) Two vols., cloth-bound, price 2s. 3d. each.

THESE volumes belong to the series of science handbooks issued by the authorities of the Victoria and Albert Museum at South Kensington. The author was for a long period secretary of the Institution of Naval Architects; he is well qualified for the task he has undertaken. Within extremely narrow limits of space (about 400 pages) he has produced a readable account of ancient and modern ships, in which a large amount of trustworthy information has been summarised and admirably illustrated. Although the original intention of these handbooks may have been the assistance and instruction of visitors to the collection of naval models in the museum, they will undoubtedly prove of interest as books of reference to all who are interested in the history of shipbuilding. Their moderate price ought to secure a large circulation.

In the first volume wooden sailing-ships are described. This part of the work was published in 1900, but has been revised and re-issued in company with the larger second part, in which the history of the era of steam, iron, and steel is traced, so far as mercantile ships are concerned. War-ships, considered as fighting machines, are not dealt with, but the influence of peculiarities in their construction upon the development of mercantile shipbuilding is illustrated. Formerly, the naval models at South Kensington included those of war-ships; when the Royal School of Naval Architecture was transferred to Greenwich (more than thirty years ago) the Admiralty also concentrated there its collection of war-ship models. South Kensington retained the mercantile models, and the present collection includes loans from private firms, as well as models which are national property. It is much to be desired that the collection should be made complete and should illustrate adequately the development of the British mercantile marine. If Sir George Holmes's handbooks should increase public interest in the collection and lead to its proper development, a good purpose will have been served. At all events, he has produced a work which will enable laymen to reach an intelligent understanding of the history of shipbuilding and the principles governing the structural arrangements of ships.

Beginning with an admirable account of ancient Egyptian vessels, the author describes boats still existing and to be seen in the Cairo Museum, although they were built nearly 5000 years ago. Ships of the Mediterranean and Red Seas—Phœnician, Greek, Roman, and Venetian—are next dealt with. Another chapter is devoted to the ancient ships of northern Europe, of which specimens have been discovered in Scandinavia in recent years.

Mediæval ships are briefly described and excellently illustrated, this section ending with an account of the famous *Sovereign of the Seas*, built about the middle of the seventeenth century A long chapter on modern wooden sailing-ships concludes this volume, and brings the history up to the construction of the great sailing three-deckers in the Royal Navy, which formed our most powerful war-ships until the middle of the nineteenth century On the mercantile side the gradual development of sailing-ships is traced, and the famous "clippers" are described

In the second volume steam navigation and the use of iron and steel for shipbuilding form the main topics. An interesting account is given of early wooden steamers It is worth note in passing that this year is the centenary of the completion of the *Clermont* by Robert Fulton, and her trials on the Hudson River The development of types of mercantile steamers is described, and numerous examples are included, amongst them being the *Great Eastern* and many vessels now employed on ocean or cross-channel service Tables of dimensions and particulars for Transatlantic steamers are given in an appendix On the structural side the book is valuable, it traces the influence of the use of iron and steel on dimensions and strengths of ships, and the differences between mercantile and Admiralty methods of construction A brief discussion of the external forces acting upon a ship at sea, and the resultant stresses on the structure, is given in one appendix, in another the puzzling subject of tonnage measurement is made as clear as it can be made to general readers This necessarily brief notice leaves many points unmentioned, the volumes should be read by all interested in the history of shipbuilding

FREQUENCY CURVES AND CORRELATION

Frequency-curves and Correlation By W Palin Elderton Pp xiii+172 (London Published for the Institute of Actuaries by C and E Layton, n d) Price 7s 6d

AS stated in a short preface by the president of the Institute of Actuaries, the object of this little volume is "to give a detailed description of the basis and practical application of those modern statistical methods that are associated with the name of Prof Karl Pearson" The work was undertaken, we understand, by Mr Elderton, at the invitation of the council of the institute, and we not only concur with the president in his commendation of the "public-spirited manner" in which Mr Elderton acceded to their request, but think that the action of the council of a professional society in thus endeavouring to place the results of recent research before the members in a convenient form for consideration is well worthy of note

In view of its purpose, the illustrations introduced are, of course, mainly of an actuarial character, but we have no hesitation in saying that the volume will be of great service to statisticians in other fields Much of Prof Pearson's work has been given in the Philosophical Transactions of the Royal Society, the *Philosophical Magazine*, and other publications which are not readily accessible to the ordinary statistician, and Mr Elderton's work will be most useful to the student by providing a short and handy summary of some of the more important results

After a brief introductory chapter, the author passes at once to the subject of frequency distributions, and the mean and standard deviation are defined (chapter ii) The method of moments is then treated in some detail, including the calculation of moments by the direct and the summation methods (iii) The deduction of Prof Pearson's curves from the hypergeometrical series is then given (iv), and their fitting by moments (v)

The subject of correlation is introduced in chapter vi , this is treated mainly from the standpoint of the normal distribution, but it is also shown that the formulæ may be regarded as obtained by the fitting of straight lines to the points in a "dot diagram," using the method of moments In chapter vii Prof Pearson's method of calculating the coefficient of correlation from any fourfold table, for measured or unmeasured characters, is described, and there follow two short chapters on probable errors (viii), and on Pearson's test for goodness of fit (ix) respectively The concluding chapter gives briefly the theory of the coefficient of contingency A few appendices deal with frequency curves other than Pearson's, with the integrals of the normal function and other matters

The exposition is careful and lucid, but some of the actuarial illustrations will prove rather a stumbling block to the non-actuarial reader Proofs are given which assume a fair mathematical knowledge, necessarily including the integral calculus, but the more lengthy and difficult proofs are omitted In some respects the work strikes one as a little limited in scope, but this arises naturally enough from the fact of its being addressed to a special public

There are only one or two points we have noted in reading that seem to call for mention In connection with the summation method of calculating moments, we would direct attention to the work of G F Lipps (Wundt's Phil Studien, xvii 538 *et seq* , 1901), and to the chapters on "die Summenmethode" in the Wahrscheinlichkeitsrechnung of Bruns (1906) Even if the *name* "method of least squares" be avoided, we would submit that this is no reason for omitting the short and simple proof that $\Sigma(x-by)^2$ is a minimum if $b=r\sigma_1/\sigma_2$ Without this proof the meaning of the coefficients of regression remains, in the general case, vague and indefinite In the chapter dealing with the coefficient of contingency, it might be as well to point out that the coefficient cannot attain the value unity unless the number of classes be indefinitely great, it cannot, in fact, exceed $\sqrt{(t-1)/t}$ for a $t\times t$-fold classification at the best

We cordially commend the volume to the attention of all students of statistics G U Y

CAVES AND WATERWAYS

La Spéléologie au XX^e Siècle By E A Martel Tome vi of *Spelunca* (Paris Société de Spéléologie, 1906)

THE completion of this volume deserves separate mention Its 800 pages contain a critical review by M Martel of practically all papers bearing on caves published in the last six years Since these papers, in their turn, refer to a large amount of earlier work, we have here a complete exposition of what is at present known of "spelæology" We pointed out, when noticing one of the separate parts, how the editor's comments render the abstracts readable and illuminating The papers have been classified, for the most part geographically, and the volume becomes practically an unconventional text-book of the lore of caves The range of subject permitted may here and there raise a smile, but it dies away in admiration of M Martel's energy Marcellin Boule, for instance, is cited on p 694 as describing a lava-flow in Auvergne intermediate in age between the epoch of the mammoth and that of the reindeer On p 727, again we read how a cave near Sévérac-le-Château —and memories of causse and cañon are recalled by the very name—was discovered in 1902 to contain a chapel, with accessories brought there during the persecution of the Catholic priests in 1793 A moment's reflection shows us that both references may prove of value Traces of man among French volcanic deposits need not be regarded as of Pliocene age The occurrence of religious emblems in caves may be due as much to a desire for secrecy as to the association of the cave itself with any form of ceremony It is thus hard to think of any worker in anthropology or natural history who would not gain information from M Martel's aid The alleged glacial deepening of Alpine valleys, and the formation of *cluses*, are discussed on p 526 Even writers on radio-activity may learn something from the notes on subterranean waters on pp 610–612 To most readers, the gradual growth of our knowledge regarding the incised drawings and paintings on the roofs and walls of caves (pp 654 705) will prove of surpassing interest M Martel presses home his contention that the bold representations of animals, sometimes amazingly faithful, are records or trophies of the chase

Three photographic illustrations are given of paintings in the cave of Altamira, near Santander, which Martel himself has visited Cartailhac (p 703) records how the discovery of these was made by a child, in the company of less observant scientific excavators Alcalde del Rio (p 704), in a paper published in 1906, mentions, in the cave of Hornos de la Peña, "a figure in a human attitude, but apparently an ape" M Martel adds that it has a tail, but why does he suggest, on p. 706, that M Piette's "être de caractère simiesque," engraved on a bone, is "probablement imaginaire"? Surely the Neolithic or even earlier artists, who saw so much that was wonderful and worth reproducing in the animal world around them, had hardly yet risen, or descended, to the consciously imaginary and grotesque?

M Piette has himself sent us a paper on "Fibules pléistocènes" (*Revue préhistorique*, 1906, p 1), in which he writes confidently as to his anthropoid from Mas-d'Azil He describes also a pendant ornament of incised reindeer-horn from Gourdan, on which a similar erect anthropoid, this time tailless, is clearly shown The figures which he publishes are of immense interest, and M Martel will doubtless note them in a future volume of *Spelunca* Though "spelæologists" cannot be allowed to found a science of their own, geologists, zoologists, anthropologists, and historians may well hope to link a friendly arm in theirs GRENVILLE A J COLE

OUR BOOK SHELF

Die chemische Energie der lebenden Zellen By Prof Oscar Loew Second edition Pp viii+133 (Stuttgart Fr Grub, 1906) Price 3 marks

THE great part played by the proteins in building up living cells has resulted in the ascription by physiologists to these substances of an indispensable *rôle* in vital processes If, however, protoplasm be regarded as a protein molecule, the difficulty at once arises how to account for the great differences in stability between the living and the dead protein This difficulty Pfluger, as well as Loew, attempts to get over by assuming a different constitution for the protein in the living body from that which is familiar to us in the dead protein as analysed in the laboratory Whereas, however, Pfluger ascribed the lability of the living protein to the presence of cyanogen groups which underwent transformation to amino-groups, Loew explains the difference by assuming the simultaneous presence in the plasma protein of aldehyde and amino groups, basing his hypothesis largely on the fact that the cells of certain vegetable organisms give a black reaction with dilute ammoniacal silver only so long as they are alive, the reaction failing when the cells have been killed by heat, acids, or alcohol

This blackening Loew and Bokorny assumed to be due to the presence of a reserve protein of special character, allied in the grouping of its constituent molecules to that which obtains in the living protoplasm

In the present book, the first edition of which appeared in 1898, the author examines the behaviour of living cells, the nature of their work, and the assimilation of food-stuffs in the light of his theory The great amount of work which has been carried out of late years by Kossel, Fischer, and their pupils on the constitution of the protein molecule, which has resulted in the separation of a large number of approximate principles, all distinguished by the possession of amino-groups, Loew dismisses with the airy suggestion that, during the action of the hydrolytic agents, acids or trypsin, a shifting of the intra-molecular groups has taken place, with the result that the amino-acids, &c, obtained at the end of the hydrolysis cannot be assumed to throw any light on the structure of the protein molecule itself Since in the plant organism it is probable that protein is formed from formaldehyde and ammonia by a process of polymerisation, the author imagines that the resulting product, in consequence of the presence of numerous aldehyde and amino-groups, must form a

molecule of extraordinary lability The first product of such polymerisation, which might be, as the author suggests, the aldehyde of aspartic acid, would further condense so as to form a body having the formula ascribed by Liberkuhn to the simplest protein This substance, "primitive peptone," by polymerisation of two molecules might form albumoses, and by the union of three molecules might form albumen

Although the facts brought together by the author are interesting, and although we must grant the possibility of aldehyde groups existing in some parts of the protein molecule, and perhaps being responsible for some of the chemical interactions which occur in the living cell, the new facts brought forward are too trivial effectively to modify our opinion on the structure of the protein molecule, which is based on the solid work of Fischer and his pupils

La Découverte de l'Anneau de Saturne par Huygens By Jean Mascart Pp 58 (Paris Gauthier-Villars, 1907) Price 2 francs

IN this small volume of 58 pages M Mascart tells the history of the discovery of Saturn's rings from the time of Galileo's dramatic anagram concerning the *altissimam planetam*, and his subsequent tragic disappointment and despair, to the time when, after many questionings and discussions Huygens finally established his accepted theory This history is most interesting, and includes a number of extracts from Huygens's corespondence on the subject, showing us how he had to fight for the acceptance of his theory and then had to fight again for the vindication of his priority in the matter The numerous reproductions of original drawings by Gassendi, Hélvétius, Riccioli, Huygens, Wallis, and others give an additional interest to the work, which is concluded by a lucid recapitulation of the later theories, such as that of Otto Struve, and discoveries concerning Saturn's unique appendage W E R

German Science Reader Part 1 Mathematics, Physics, and Chemistry Compiled by C R Dow Pp 85 (London J M Dent and Co, 1906) Price 2s

TWENTY pages of this book are devoted to mathematics, twenty-three to physics, nineteen to chemistry, and the remainder to a vocabulary of words not usually found in elementary class-books of German The mathematical portion is a synopsis of principles of mathematics with enunciations of problems, while the two remaining sections consist of definitions and descriptions of some physical and chemical properties of matter Any student of science who has an elementary knowledge of the German language should be able to read the book with the aid of the vocabulary, and the task would be more to his taste than reading or translating Grimm's or Andersen's fairy-tales No grammatical rules are given, as instruction in these is assumed to have been obtained in an earlier course

Céruse et Blanc de Zinc By M G Petit Pp 154 *Préparation mécanique des Minerais Résumé pratique* By F Rigaud (Paris Gauthier-Villars and Masson et Cie, n d)

BOTH these volumes are publications in the now well-known "Encyclopédie Scientifique des Aide-Mémoire" The first deals with the preparation and use in painting of white lead and zinc white respectively The second book provides a practical account of the various processes in use for the mechanical preparation of ores by separating them from their stony matrix

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

The Ballot-Box.

IN reference to the weight judging competition, Mr Galton says that "the average competitor was probably as well fitted for making a just estimate of the dressed weight of the ox as an average voter is of judging the merits of most political issues on which he votes" These competitions are very popular in Cornwall, but I do not think that Mr Galton at all realises how large a percentage of the voters—the great majority, I should suspect—are butchers, farmers, or men otherwise occupied with cattle To these men the ability to estimate the meat-equivalent weight of a living animal is an essential part of their business, and, as an instance of their training I may mention that one of the butchers here has a son under thirteen years of age who is an adept at this work, and is already, I am told, one of the best weight judges in the district This boy has been trained to it by his father, and already surpasses his instructor Moreover, many of the competitors doubtlessly compete frequently, compare notes afterwards, and correct future estimates by past experience Now the point of all this is that, in so far as this state of things prevails we have to deal with, not a *vox populi*, but a *vox expertorum* I am afraid that the majority of such competitors know far more of their business, are far better trained, and are better fitted to form a judgment than are the majority of voters of any party and of either the uneducated or the so-called "educated" classes I heartily wish that the case were otherwise

F H PERRY COSTE

Polperro, Cornwall March 21

I INFERRED that many non-experts were among the competitors, (1) because they were too numerous (about 800) to be mostly experts, (2) because of the abnormally wide vagaries of judgment at either end of the scale, (3) because of the prevalence of a sporting instinct such as leads persons who know little about horses to bet on races But I have no facts whereby to test the truth of my inference It would be of service in future competitions if a line headed "Occupation" were inserted in the cards, after those for the address FRANCIS GALTON

MR HOOKER, in NATURE of March 21 seems not to have quite appreciated my principal contention in the letters "One Vote, One Value" and "Vox Populi" of February 28 and March 7 respectively It was to show that the verdict given by the ballot box *must be* the Median estimate, because every other estimate is condemned in advance by a majority of the voters *This being the case* I examined the votes in a particular instance according to the most appropriate method for dealing with medians, quartiles, &c I had no intention of trespassing into the technical and much-discussed question of the relative merits of the Median and of the several kinds of Mean, and beg to be excused from not doing so now except in two particulars First, that it may not be sufficiently realised that the suppression of any one value in a series can only make the difference of one half-place to the median whereas if the series be small it may make a great difference to the mean, consequently, I think my proposal that juries should openly adopt the median when estimating damages and councils when estimating money grants has independent merits of its own, besides being in strict accordance with the true theory of the ballot box Secondly, Mr Hooker's approximate calculation from my scanty list of figures, of what the mean would be of all the figures, proves to be singularly correct he makes it 1196 lb (which is the mean of the deviates at 5°, 15° 95°), whereas it should have been 1197 lb This shows well that a small *orderly* sample is as useful for calculating means as a very much larger *random* sample

and that the compactness of a table of centiles is no hindrance to their wider use I regret to be unable to learn the proportion of the competitors who were farmers butchers, or non-experts It would be well in future competitions to have a line on the cards for "occupation" Certainly many non-experts competed, like those clerks and others who have no expert knowledge of horses, but who bet on races, guided by newspapers, friends, and their own fancies

FRANCIS GALTON

Ketene

WHILE engaged in a research on the polymerisation of unsaturated compounds, we were led to try the action of a strongly heated platinum wire on various organic substances It is unnecessary at this stage to discuss our general results, and we will therefore deal at once with the action of the wire on acetic anhydride This substance when treated with the hot wire yielded a compound boiling about −65° and freezing about −130° which on standing at ordinary temperatures condensed fairly rapidly, yielding a brownish-yellow oil which, like the gas, has an extremely pungent smell We have not yet succeeded in obtaining the new body in a completely pure state, but as our work has been interrupted for some time, we venture to give the following preliminary data

On exploding one volume of the gas with excess of oxygen, there was a contraction of 1·01 volumes, and 1·85 volumes of carbon dioxide were formed while 1·86 volumes of oxygen had disappeared The corresponding numbers for the reaction $CH_2 CO+2O_2=2CO_2+H_2O$ are 1 1 2 2

Another sample gave a density of 39·9 ($H_2=2$), while that calculated for $CH_2 CO$ is 42 This sample was, however far from pure

The gas is absorbed by all the ordinary reagents, including water It combines with bromine, and appears to give a crystalline compound with bisulphites It chars when treated with phosphorus pentoxide or concentrated sulphuric acid These two reagents themselves produce traces of the gas when they are allowed to act on acetic anhydride We would add that we have also obtained the substance from acetone and it seems probable that it can be obtained by our method from all substances containing the group —CH_2—CO—

We would suggest that the body is the parent substance of Staudinger's ketenes We hope to be able to publish a fuller communication shortly

Technical Terminology

THE writer on engineering terms in NATURE of March 21 (p 490) says that a single word is required to denote a central electric generating station

Perhaps *megadyne* would be acceptable, signifying "great power," and suggestive of the dynamo equipment of the station As a convenient abbreviation *mega* would readily enter into common use

HIGHER EDUCATION IN THE UNITED STATES

THE most recent report issued from the United States Bureau of Education at Washington gives detailed information respecting recent developments of the various grades of education in the States down to June 30, 1904, and in it the Commissioner of Education gives a prominent place to the work of universities and colleges The statistics now provided make it possible to supplement the article published in these columns (vol lxviii, p 25) dealing with university education in the United States, and to give some indication of the progress which has been made in American institutions of higher education during recent years

There has been, in the first place, a large increase in the number of students attending universities and colleges in the United States. Whereas in the year 1899–1900 the total number of men students was, roughly, 61,800, and of women students 25,300, the numbers in 1903–4 had become, for men, nearly 72,000, and for women nearly 31,000.

The number of professors and instructors has increased in a similar manner In 1899–1900 the number of such teachers in institutions for men and for both sexes was 12,664 men and 1816 women, in 1903–4 these numbers had become 15,342 men and 2272 women In institutions for women alone the increase is not so decided The number of men teaching in these institutions was in the former year 697, and in 1903–4 only 631 The number of women, however, shows a marked increase from 1744 to 1834

It is interesting and instructive, too, to study the rise and fall in the popularity of the various subjects taken up by students At the two periods under comparison there were some remarkable differences In 1899–1900 the number of students studying classics and other subjects of general culture (as the report calls it) was roughly 57,000, but in 1903–4 the number had reached 65,000 In the earlier year the number of students in classes of pure or applied science was well on towards 26,000; in 1903–4 this number had increased to 32,000 The relative popularities of humanistic and practical studies may be said to have undergone little change at institutions of the rank under consideration But in this connection it must be remembered that at the great technological institutions, which are not included in these statistics, large numbers of men are engaged entirely in studying branches of applied science

The total value of property possessed by the institutions for higher education in the United States amounted in 1899–1900 to about 72,120,000*l*, and in 1903–4 this large sum had increased to 93,043,000*l* The endowment funds in the former year were valued at 33,240,000*l*, while in the latter year this provision for future contingencies had grown to 41,313,000*l*.

The value of gifts and bequests received by institutions for higher education during 1899–1900 was 2,399,000*l*, in 1903–4 the amount had increased to 2,740,000*l*, and last year as much as 5,000,000*l* was raised in this way Twenty-five institutions in the former year received from private donors gifts of as much as 20,000*l*, and in 1903–4 as many as twenty-nine institutions were equally fortunate

For the first of the years with which we are concerned in this comparison, the total income, excluding benefactions, amounted to 5,712,000*l*, of which about 2,234,000*l* was received in the form of tuition and other fees In 1903–4 the total income had reached 8,066,000*l* In connection with this sum, the Commissioner for Education remarks —"It is a well-known fact that the income derived from fees received from students forms only about one-third of the total income the remainder necessary to meet the expenses of the institutions being derived from endowment funds, State aid, and miscellaneous sources."

In 1903–4 the State and municipal aid to higher education amounted to 1,984,600*l*, as compared with 893,000*l* in 1899–1900

It is thus seen that the striking disparity between public and private efforts in behalf of higher education in the United States and Great Britain, pointed out in the article to which reference has already been made, has, in the interval of four years with which we are here dealing, become more accentuated, and, instead of having made up leeway, we appear to have fallen even further behind

The annual amount raised by private munificence for American universities and colleges has in a few years been doubled; and, as recent notes in these columns have shown, there is no sign of any decline in the generosity of the men of wealth in the States. The amount of money raised in this way in the United Kingdom during the period 1871–1901 was only one-eighth of that contributed in the United States in the same time; and if the present scale of American gifts be continued, the comparison at the end of 1931 will be such as to leave us at a still more hopeless disadvantage.

All the statistics here brought together tell the same story; alike as regards number of students, number of university teachers, total value of university property and total annual income, from whatever point of view looked at, there is evidence of a strong and healthy growth in the system of higher education in the United States, and, though it can by no means be suggested that similar work in this country has remained stagnant, the most optimistic student of British affairs will hardly maintain that our universities and colleges can show progress and development at all commensurate with that the report of the Commissioner of Education reveals as true of the United States. It is clear that patriotic men of science among us cannot afford to relax their efforts to increase the efficiency of our universities and colleges, and to supplement their number. Students of science do not need to be reminded of the intimate connection between cause and effect but it behoves them to take every opportunity to convince statesmen and the public that industrial supremacy is, in the long run, one of the effects of an adequately equipped and generously endowed system of higher education.

A. T. S.

THE ASIATIC SOCIETY OF BENGAL

THE Asiatic Society of Bengal, since its foundation in 1784 by that pioneer of oriental studies, Sir W. Jones, has played a leading part in the exploration of the natural history, philology, antiquities, and other branches of scientific inquiry connected with the East. Its Journal has been enriched by contributions from many eminent authorities, among whom may be named, in addition to its founder and older scholars such as H. H. Wilson, Prinsep, Sir A. Cunningham, Jerdon, Blyth, and Ball, men like Drs. Hoernle, Grierson and Annandale, Messrs. T. H. Holland and V. A. Smith, who are happily still at work. Like all scientific organisations in the East, it has suffered vicissitudes. The short and broken residence of Europeans in the country, pressure of official work, lack of native co-workers, want of libraries of reference, and last, not least, the indifference of the Indian Government, which prefers that its servants should devote their spare time to the judgments of the High Courts or the circulars of the Board of Revenue rather than to the science and literature of the country, have at times interrupted its progress. But under its present managers it seems to be inspired by a new spirit of enthusiasm. Its membership has increased within the last year by more than 50 per cent., the Indian Government has at last begun to regard it seriously, and through the Lieutenant-Governor of Bengal, who now acts as president, has suggested a scheme for bringing its work into closer relation with that of European officials.

These gratifying signs of progress are reflected in its new publications. Besides its well-known Journal, it has commenced the issue of a series of monographs prepared by competent writers, well illustrated and sold to the public at a very moderate price. These memoirs cover a wide range in the fields of natural science, philology, and anthropology. Among the most energetic naturalists is Dr. N. Annandale, the author of "Fasciculi Malayenses" and a study of primitive life in the Hebrides and Orkneys, who has now found a fresh field of activity as curator of the fine Calcutta collections. It is one of the ironies of fate that his name will survive in the scientific literature of the future linked with that of a new species of earwig, *Anisolabis annandalei*. He has recently contributed to the Journal a valuable series of papers on the fresh-water fauna of India, special monographs on Malaysian barnacles and the common Hydra of Bengal, and has opened an almost new field of study in his monograph on the "Fauna of a Desert Tract in South India," Rāmanād, in the Madura district, a region which might naturally, for zoological purposes, be regarded as worked out, but where his trained eye has discovered much new and interesting material.

In anthropology the society is judiciously working in connection with the Ethnographical Survey recently revived and extended by Lord Curzon, and has received from it several valuable communications. Mr. Sherring, who recently published an account of explorations in western Tibet, gives a further account of the Bhotiyas and Mr. A. H. Francke of the Dards of the same region, the late Father Dehon, S.J., describes the religion of the Uraons of Bengal, and Mr. E. H. C. Walsh discusses the remarkable cup-mark records in the Chumbi Valley. Here, again, Dr. Annandale has made a new departure in the first of a series of notes dealing with the arts, industries, and implements of the more primitive tribes, which describes the blow-gun, which seems to have been imported into southern India by the Malays. Studies such as these will, we trust, lead to the foundation of an Indian Pitt-Rivers museum, the ample materials for which at present in existence will soon disappear unless their collection is taken up in earnest.

In another direction the society has started a valuable work by establishing a medical section, which proposes to organise the workers now engaged in the study of tropical disease. In this connection the monograph by Messrs. Hooper and Mann on earth-eating, already described in NATURE (vol. lxxiv., p. 543, September 27, 1906) is full of interest. This remarkable craze appears to be spreading rapidly among the coolies in tea-gardens in Assam, and the dangers resulting from the practice are attracting serious attention. It is not a racial characteristic, but is found in all parts of the country; it appears to depend on the purely mechanical effect of various kinds of earth in relieving gastric or intestinal irritation. When once indulged in, the craving becomes uncontrollable, and leads to serious disease of the digestive canal.

All classes of students will accept these new publications as a record of excellent scientific work, and will congratulate this historic society on its recent satisfactory progress.

ROBERT WARINGTON, F.R.S.

WE regret to learn of the death of Mr. Robert Warington, F.R.S., at Harpenden on March 20. Mr. Warington was the son of Robert Warington, F.R.S., for a long time chemist for the Society of Apothecaries, and was born in 1838. Being of delicate health, he was educated entirely at home, and learnt his first chemistry from his father. In 1859 he worked for some time as a voluntary assistant in the Rothamsted Laboratory, and in 1862 went to the Royal Agricultural College at Cirencester as assist-

ant first to the late Dr Augustus Voelcker, and then to Prof A H Church In the next nine years Warington was chemist at Sir John Lawes's tartaric acid works, but in 1876, being desirous of devoting himself entirely to research, he came again to the Rothamsted Laboratory, where he remained until 1890

Although Warington's chief interest was in agricultural chemistry, he published a number of papers dealing with inorganic chemistry, and a detailed account of the various salts of tartaric and citric acids as they occur in their natural sources and in the manufacture of these substances

On his return to the Rothamsted Laboratory in 1876, Warington introduced several improved methods of analysis to save time or ensure greater accuracy in the routine determinations, there also he carried out the investigations on nitrification by which he made his name In 1877 appeared the paper of Schloesing and Muntz which showed that the production of nitrates in the soil must be due to living organisms, this work was repeated by Warington, who continued to investigate the conditions favourable to the process He showed that light would inhibit the change and that the drying of the soil was sufficient to destroy the organism, he also investigated the distribution of the organism, and showed that it was confined to the surface layers of ordinary soil, being only present in any quantity in the portion usually stirred by the plough Observing that the oxidation of the ammonia or urea employed sometimes stopped at the stage of nitrite, he succeeded in demonstrating that the process in ordinary soils takes place in two stages due to different organisms, one oxidising ammonia to nitrous acid, the other completing the oxidation to nitric acid Warington had actually accomplished the final step in the isolation of the two organisms, though he had not brought his work to the stage which satisfied himself, when his researches were unfortunately interrupted, and before he could resume Winogradsky published his elegant method of isolating the nitrous and nitric organisms by the use of a nutrient silica jelly

The circumstances which led to Warington thus missing the credit of the crowning point of his long researches on nitrification undoubtedly caused him bitter disappointment, he continued to live in Harpenden, but took no further part in research In the course of his investigations on nitrification Warington also observed and studied that other process of denitrification, by which previously formed nitrates are reduced again often with loss of the nitrogen as gas In later years this subject became very prominent for a time but the essential conditions of the action had been laid down before in Warington's papers He also investigated the method of estimating small quantities of nitrates by means of indigo and devised a standard process which, in a simplified form is now used by most water analysts

Warington gave a course of lectures in America for the Lawes Agricultural Trust in 1891, these were afterwards published by the United States Department of Agriculture, he was also Sibthorpian professor of rural economy at Oxford, 1894–7

His "Chemistry of the Farm" was published in 1881, and has since gone through fifteen editions, though only a small book, it is noteworthy for its lucidity and compactness in the handling of a mass of experimental data it is a model text-book which has no rival in any language, and on it the present generation of agricultural chemists in this country has been educated

Warington was elected to the Royal Society in 1886, his connection with the Chemical Society, of which his father was one of the founders, dates back to 1863, he was vice-president from 1889 to 1893, and in its Transactions appeared nearly all his original work

Warington's scientific work is distinguished by clearness and precision, the range is not wide, but everywhere it shows the minute care and the regard for accuracy with which he worked, in these respects his work only reflected his personal character.

A D. H

M P E BERTHELOT

THE death of M Berthelot was briefly recorded in the columns of NATURE last week The writer has been asked, as a former pupil of the great master, to give some account of his life and work

Marcelin Pierre Eugène Berthelot was born in Paris on October 25, 1827 He was the son of a medical man, Dr Jacques Martin Berthelot, and was educated at the Lycée Henri IV. In 1846 he obtained the prix d'honneur de philosophie at the concours-général, open to the best students of the highest classes of the lycées of Paris In February, 1851, he became assistant (préparateur) to Balard, the discoverer of bromine, who held the chair of chemistry at the Collège de France He kept this minor position until December 1859, when he was appointed professor of organic chemistry at the École supérieure de Pharmacie In 1865 a chair of organic chemistry was created for him at the Collège de France, which he held until his death In 1870–1 he acted as president of the Comité scientifique de défense during the siege of Paris In 1873 he was elected member of the Academy of Sciences, of which he afterwards became perpetual secretary In 1876 he was appointed inspector-general of higher education, in 1881, senator for life He was Minister of Public Instruction from December, 1886, to May, 1887, and Minister of Foreign Affairs in 1895–6 In 1900 he was elected a member of the French Academy

The French nation has from the time of the Revolution turned more than once to its scientific men for help in the conduct of national affairs The names of Lavoisier, of Lazare Carnot, mathematician and organiser of victory, of Fourcroy, of Dumas, and of Paul Bert recur to the memory But if Berthelot took an untiring part in public affairs, and especially, as member of the Conseil supérieur de l'Instruction publique, in educational affairs, it is not as an administrator or as a minister that he will be remembered, but as a chemist, and perhaps the greatest, as he was the most prolific, chemist of his age

Of his first studies in chemistry I have found no account, but we know that Claude Bernard in 1848 asked him for chemical assistance in his early work on glycogen

It was in 1850 that he published his first paper, on a method of liquefying gases Between that date and 1883 the Royal Society's catalogue records against his name the titles of between 600 and 700 papers, it is probable that their total number falls little, if anything short of a thousand, and to these must be added eighteen or twenty books, some of them, it is true, being only the summaries of published papers, but others, and especially his works on the history of chemistry, in a large measure independent publications To estimate justly the value and influence of this colossal contribution to science would be the work of months rather than of a few hours, and, indeed, the very mass of the work has perhaps hidden something of its significance and of the importance of the underlying ideas

Berthelot first gave his measure in his doctoral

thesis on glycerin and the fats, published in 1854. Chevreul had compared the fats to compound ethers, or esters, as we should now call them. Berthelot showed that the relation of glycerin to ordinary alcohol was comparable to that of phosphoric acid to nitric acid, thus introducing the important notion of polyatomic alcohols into chemistry. By a curious slip, inconsistent with the facts he had discovered, Berthelot compared the three series of glycerin esters to the orthophosphates, pyrophosphates, and metaphosphates, instead of to the neutral and "acid" salts of orthophosphoric acid. It was reserved to Wurtz, his great rival, to give the fullest interpretation and extension to his discovery.

The next question to which Berthelot devoted himself was a larger one. Gerhardt, who in the 'forties had contrasted the analyses of the chemist with the organic syntheses of nature, effected by the help of "vital force," already in 1853, in the introduction to his "Traité de Chimie organique," described as the object of chemistry:—"la connaissance des moyens de composer tous les corps, la connaissance des moyens de décomposition n'en étant que le préliminaire obligé." But at that time the only organic compounds that had been synthesised from their elements were urea, by Wöhler, and acetic acid by Kolbe. Berthelot set himself the great task of synthesising from their compounds the fundamental organic compounds, marsh-gas, formic acid, methyl and ethyl alcohol, acetylene, benzene—and succeeded. His work overthrew the 'vital force' theory as applied, not, indeed, to living matter, but to its non-living products. It forms the basis of those syntheses which have perhaps given to the chemistry of the nineteenth century its greatest prestige in the eyes of the world.

In his work on the fats, Berthelot had shown that they could be produced by the direct action of glycerin on the fatty acids, provided that time were given; it was characteristic of the man to generalise from this single discovery. In his work with his pupil, Péan de St. Gilles, on chemical affinity, published in 1862–3, he first introduced into chemistry the study of rates of reaction and of reversible reactions. Few single researches in the history of chemistry have been more fruitful of results.

He next set himself a task comparable to the work on organic synthesis. C. L. Berthollet in the early years of the nineteenth century had written a famous treatise on chemical statics; it was Berthelot's ambition to lay the foundation of chemical mechanics as a whole by a systematic study of the heat-changes involved in chemical reactions. Andrews, Hess, Favre and Silbermann, and others had carried out isolated investigations in this domain, but Berthelot, and almost simultaneously Thomsen, the Danish chemist, set out to investigate the whole field of thermochemistry systematically. In his "Mécanique Chimique fondée sur la Thermochimie," published in 1879, Berthelot gives the result of fifteen years' assiduous work. Full of brilliant discoveries of detail, of ingenious methods of experiment and calculation, the work cannot be said to have realised to the full the ambitions of its author. The "principle of maximum work," which he regarded as his greatest generalisation, is incomplete. But his work is, nevertheless, monumental in extent, and forms the necessary starting point for all fresh researches on the subject. In 1897 he published a vast collection of thermochemical data under the title "Thermochimie, Données et Lois numériques."

In one branch of thermochemistry, that of explosions, Berthelot's discoveries are as novel as they are fundamental. Working mainly with his pupil Vieille, he found that when an explosive mixture or compound is fired, the flame proceeds through the mixture at a gradually increasing rate until a maximum rate is attained, of which the value depends on the chemical composition of the explosive. This is the phenomenon of the "onde explosive," or explosion wave, especially familiar in this country through the remarkable work of Dixon, carried out subsequently. It was in the course of his work on explosive mixtures that Berthelot invented the well known calorimetric bomb, an extremely simple and accurate instrument for determining the heats of combustion of organic compounds.

The problems of vegetable chemistry began to interest Berthelot in 1876, when he showed that nitrogen could be made to combine directly with carbohydrates under the influence of the silent electric discharge. Later he found that the microbes of the soil played an important part in the fixation of nitrogen in the vegetable tissues—a discovery to which the work of Hellriegel and Wilfarth on leguminous plants gave the most brilliant confirmation.

In 1884 a fine laboratory was built for him on the heights of Meudon, and here, with the devoted and able collaboration of M. G. André, he carried out the vast series of researches on vegetable chemistry recorded in the four volumes on "La Chimie végétale et agricole," published in 1899.

Berthelot's work in the history of chemistry is on the same kind of scale as his experimental work. In a first book, "Les Origines de l'Alchimie," he traces alchemy to its origin in a combination of the ideas of Egyptian metal-workers (who from the practice of making alloys naturally desired to economise the use of the precious metals in their production) and of the Greek ideas of the transmutation of elements current in the school of Alexandria. In 1887–8 he published a more comprehensive work, in collaboration with C. E. Ruelle, the "Collection des Alchimistes grecs." This was followed in 1893 by a similar work, "La Chimie au Moyen-âge," which deals with the Syriac and Arabic alchemists translated by MM. Rubens Duval and Houdas. The author showed that the Latin works previously attributed to Geber (or Djaber, as he should be called) were late forgeries, and published authentic texts of the famous alchemist. These he supplemented in his last work, "Archéologie et Histoire des Sciences" (published in 1906), by printing the Latin translation of another work of Geber, the "Liber de Septuaginta," of which the Arabic original has been lost, together with a number of fresh memoirs on mediæval chemistry and on the composition of metallic specimens of Egyptian, Chaldaic, Persian, and Roman origin. On the more modern history of chemistry he published a book on Lavoisier, "La Révolution chimique" (1890), containing extracts from Lavoisier's note-books, and "La Synthèse chimique" (1875).

Besides these works and practical treatises on calorimetry and gas analysis, he published a number of volumes of essays—"Science et Philosophie" (1886), "Science et Morale" (1897), "Science et Éducation" (1901), "Science et Libre-Pensée" (second edition, 1905), and the correspondence with Ernest Renan, who in his "Souvenirs d'Enfance" has left so interesting an account of the beginnings of the life long friendship of the two men, was issued in 1898.

The "Cinquantenaire scientifique de M. Berthelot" gives an account of the jubilee celebration held at the Sorbonne on November 24, 1901, when, in the presence of the President of the French Republic and the great officials of State and of the learned bodies of France, M. Berthelot received the congratulations of the academies of the world. "Dès que vous abordez une question," said Moissan in addressing him on

behalf of the French Academy of Sciences, "vous l'étendez en la généralisant" But few men have united with the power to generalise such marvellous quickness and tenacity in working out detail That quickness and tenacity may be estimated by the volume of his work In his later life he had, of course, much help, but in his earlier years, when he often passed the night in the laboratory, he worked single-handed Berthelot rejected until well into the 'nineties (as Bunsen did until his death) the use of the atomic notation, chiefly perhaps from a horror of the enthusiastic and somewhat uncritical faith of contemporaneous exponents of the atomic theory

In person Berthelot was short and slight, and with the stoop of the student In lecturing he spoke rapidly and in a low voice, with no attempt at oratorical effect But his fine, regular features and brilliant blue eyes left an impression not easily to be forgotten Reserved and almost cold in manner, he cared for two things supremely, his work and his family He survived the shock of his wife's death, which took place on March 18, only by a few minutes

The French Parliament voted a public funeral, it took place on Monday in the Panthéon, where the remains of his wife rest beside his own

M Berthelot left a daughter and four sons, of whom one, M Daniel Berthelot, is well known for his researches in physical chemistry, and occupies a chair at the Ecole supérieure de pharmacie

P J HARTOG

NOTES

MEN of science in this country will probably have to wait a long time before they will see the Government and the nation pay such a tribute to the greatness of one of their number as was witnessed in Paris on Monday, when the national funeral of M and Mme Berthelot took place at the Panthéon Here politicians and people have little sympathy with intellectual greatness, and if M Berthelot had lived in Great Britain instead of France his death would have been mourned by the world of science but the Government would certainly not have hastened to secure for him the honour of a national funeral because our statesmen do not know the influence of scientific work on national character and progress, and to them men of science live in a world far beyond the range of practical politics where virtue finds its own reward To understand the right spirit of appreciation of a great man of science we have to cross the Channel and be present at a funeral like that of M and Mme Berthelot, for on such an occasion the French manifest incomparable qualities of organisation and tact From the report of the Paris correspondent of the *Times* we learn that not since the funeral of Ernest Renan have the population of the capital been invited to join the authorities in such a solemn demonstration of mourning for one of their great compatriots Amid impressive surroundings all that is representative of the dignity of the State was assembled from the President of the Republic to the members of the several academies, the council of the Legion of Honour, the Ministers, the members of Parliament and a host of the most eminent personalities of France After a portion of Beethoven's Symphony in C minor had been rendered, the Minister of Education, M Briand, ascended a small platform erected near the academicians and read a funeral oration in which he worthily honoured the illustrious dead Berthelot's attitude towards the religious sentiment he accurately summarised in the terms of a formula borrowed from Renan—"The real way of adoring God is to know and love what exists" Respecting Berthelot as a *savant*, he dwelt particularly on his *rôle* as a creator, the forerunner of more startling syntheses still The great moral quality of the man, the natural consequence of his philosophical ideas, was tolerance After the oration, the two coffins were carried to the peristyle of the Panthéon, where a monumental catafalque had been raised A splendid military pageant followed, the troops defiling past the coffins to the strains of the "Chant du Départ" and "Les Girondins," while flags were lowered and swords raised in salutation of the dead In the afternoon the public was allowed to visit the Panthéon, and in the evening the bodies were taken to the Panthéon vaults, where they occupy provisionally a place next to the remains of Victor Hugo

SCIENTIFIC men will do well to watch the course of events connected with the subject of Mr Haffkine's prophylactic and the Mulkowal accident, referred to by Prof Ross in last week's NATURE, as it is important that laboratories engaged in making prophylactics and sera shall not be lightly discredited on inadequate evidence—important not only for the laboratories but for the public, which in its alarm is led to reject these valuable agents In the House of Commons on March 20 Mr Morley gave a cautious written reply to a question by Sir W Collins on the subject He stated that Mr Haffkine is still in the employment of the Government of India, and has been offered "employment in that country on research work at a salary equal to that of which he was in receipt when he left India" But it is understood that Mr Haffkine is holding out not for the loaves and fishes of office, but for the vindication of himself, his laboratory, and his science from what appears to have been at least a very doubtful verdict Mr Morley also stated, somewhat too cautiously that "Dr Haffkine's prophylactic continues to be one of the precautions which are recommended by Government to the general populations against outbreaks of plague" But this is quite an inadequate description of it Mr Morley appears to have overlooked the facts that in official statements other measures such as segregation, disinfection, and evacuation, have been declared to be unavailing, that in the epidemic now raging in the United Province of Agra and Oudh, the Government of the province reported only last month (*Bombay Gazette*, February 18) to the effect that the prophylactic was the only measure affording real and substantial protection, and that in the Punjab alone up to October 1903, 1 327,075 people had been inoculated, with a declared reduction of mortality to about one-twelfth that occurring in the uninoculated (report on plague and inoculation in the Punjab by the chief plague medical officer, Lahore, 1904) But Mr Morley may be trusted to see that justice (and, let us hope, something more) is done in this case

LORD KELVIN, O M, has been nominated as president-elect of the Institution of Electrical Engineers for the session 1907–8, his term of office as president to begin next November Prof J J Thomson has been elected an honorary member of the institution

LORD AVEBURY will preside at the annual soirée of the Selborne Society, which will be held at the Civil Service Commission (Old London University), Burlington Gardens, on Friday, April 26 Illustrated addresses will be given, and there will be a display of microscopes and objects of interest

A *Times* correspondent at Kingston, Jamaica, reports that earthquake shocks are recurring with alarming frequency, the latest being at 1 30 a.m on March 25 All

the shocks have been sharp, though short, and accompanied by loud subterranean rumblings.

THE *Pall Mall Gazette* states that Mr Franz Herger, director of the Meteorological Observatory of the St Gothard, was caught by a snowstorm while returning from the observation tower, and his dead body was found a few days ago, almost completely covered with snow, near the Lucendro Bridge

THE seventy-ninth meeting of the German Association of Naturalists and Physicians will be held at Dresden on September 15–21 General meetings will be held on Monday, September 16, and Friday, September 20 at which lectures will be given by Profs Hempel (Dresden), Hergesell (Strassburg), Hoche (Freiburg-im-Baden), and Strassen (Leipzig) The sections will meet on September 16, 17, and 18 There will be a section of geophysics, meteorology and terrestrial magnetism, and anyone desiring to give a short lecture or demonstration to the section should communicate before May 25 with Prof Paul Schreiber, Direktor des K Met Instituts, Dresden-N 6 grösse Meissner Strasse 15

WE regret to see the announcement that Prof E von Bergmann, professor of surgery in the University of Berlin since 1882, died at Wiesbaden on Monday, March 25 in his seventy-first year For a few years before his appointment to his Berlin chair and to the directorship of the University Clinical Hospital he was professor of surgery at Würzburg An obituary notice in the *Times* records that in Berlin von Bergmann devoted himself to the development of Lord Lister's antiseptic methods and became one of the leading exponents of the purely aseptic treatment which dispensed with the carbolic spray, and relied upon the prevention of infection by means of perfect cleanliness His success was especially remarkable in operations upon the skull and the brain, and surgery owes to him considerable advances in this particular department of its labours After the death of Prof Virchow, von Bergmann became the most eminent representative of the German medical world, and he was a present or a past president of the leading medical and chirurgical societies Last year he was made a life member of the Upper House of the Prussian Diet German and foreign universities honoured him by the bestowal of their academic degrees, and only last December he celebrated his seventieth birthday, and received tributes of admiration and esteem from the leading members of his profession at home and abroad.

THE motion for the second reading of the Weights and Measures (Metric System) Bill was defeated in the House of Commons on March 23 by a majority of 32, 118 voting for the second reading and 150 against The Bill proposed that from April 1 1910 or at a later date to be fixed by Order in Council, the standard metre and kilogram should be established and that sales and contracts should thenceforth be made according to the metric system Mr Strauss, in moving the second reading, said that resolutions in favour of the Bill have been passed by the London County Council, large numbers of chambers of commerce, and many local authorities, and it is supported by the heads of many trade and engineering firms and numbers of trade unions He asked the House to give the Bill a second reading for three reasons —the loss of time and money in business and trade involved in the present system, the most serious waste of time in the education of children; and the loss of commerce with other countries owing to our dealing in weights and measures which to them are incomprehensible The incongruities and absurdities of the cumbersome British units of weights and measures were exhibited by Mr Strauss and Sir H Norman, who seconded the motion while the latter gave a convincing exposition of the simplicity and interdependence of the metric weights and measures

THE opposition made out a strong case against the Metric System Bill referred to above Mr Haworth urged that 80 per cent to 90 per cent of the engineers of this country are against the Bill, and that it had been estimated that in engineering alone the cost of the change would be 100 million pounds In shipping, measurements of draught, displacement, and tonnage, which are nearly universal on the British standard, would have to be altered throughout the world The cotton trade, again is carried on all over the world on the English measure Similar cases were quoted by subsequent speakers and it was also maintained that the greater part of our trade is with non-metric countries, and that unless the colonies and the United States adopted the change with us few of the advantages offered by the metric system could be reaped The metric system was legalised in Great Britain several years ago and the manufacturers of the country can adopt it when they find it to their interest to do so In commerce as in science it is desirable to secure international standards so far as possible, and the metric system has been adopted by many countries, and has become the basis of scientific measurements, because it provides simple and satisfactory standards An international system of weights and measures may be as impracticable as an international language but the advantages of either of these common means of expression are obvious When traders and manufacturers find that the metric system must be adopted in order to have commercial relations with other countries they will no doubt adapt themselves to the new circumstances Until some common agreement has been arrived at among leading business men, it can scarcely be urged that Parliament should make compulsory a system which would involve an industrial revolution

THE anniversary dinner of the Chemical Society was held on March 22 Prof Meldola, president of the society being in the chair Lord Rayleigh proposed the toast of ' The Chemical Society and he is reported to have said in the course of his remarks that an ardent student, if he is so disposed can become the parent of a new substance Others of maturer age look upon this increase of the chemical population as rather an embarrassment No doubt there is a multitude of details, and one can only hope that in the course of time generalisation may arise and be established which will supersede much of that detail, link it together and so render it no longer so serious a burden upon the memory In replying to the toast Prof Meldola said in its intimate relations with other branches of science chemistry is as far-reaching is cosmopolitan has as many points of contact with all branches of science organic or inorganic as any branch of science that is being cultivated at the present time He expressed regret at the enormous wastage of chemical talent and faculty going on all over this country, and said the society could do very much if it had larger resources to fall back upon The research fund should be in such a position that the society could afford to give personal grants to workers to enable them to secure the services of competent men to cooperate with them in their work. The toast of ' Scientific Societies ' was proposed by Sir

William Ramsay, and responded to by Lord Kelvin and Prof Ray Lankester Prof Lankester agrees that there is a need for great endowments for furthering chemical science and, indeed, the various departments of the whole scientific field, and that if learned societies make it known that they will administer those funds, the money will be forthcoming He considers it would be better to give money in this way than that it should be given, say, to universities, which Prof Lankester is unable to regard as promoters of scientific knowledge in this country Sir A Rucker however, in responding to a later toast, said that he has cherished as part of his creed that the business of a university is not only to teach, but to add to knowledge The Foreign Office and the Royal Society asked the University of London to undertake the establishment of a chair of protozoology, and it was done As Prof Lankester acted as the adviser of the Royal Society in this matter Sir Arthur Rücker thought the action was proof enough that he really believed in research by a university

In an article on the evolution of the horse family published in the March number of the *American Journal of Science* Mr R S Lull gives a series of diagrams illustrating the differences in relative size and form of the various generic types When referring to the suggestion that the one-toed Siwalik hipparion may be the ancestor of the zebras, the author is oblivious of the view that the latter form a mixed group one of the members of which is closely allied to the wild ass A paper by Mr C W Gilmore on a new species of the ichthyosaurian genus Baptanodon from Wyoming is also included in the same issue

The fifth annual report of the Philippine Bureau of Science (published at Manila in 1906) shows that the society did excellent work during the twelvemonth under review although its efforts were considerably hampered for lack of sufficient accommodation Special attention was directed to the prevention of cholera by means of cholera vaccine Although eradication of the disease seems impracticable it appears to be a fact that the vaccine confers a blood-immunity greater than that resulting in the case of typhoid by the use of typhoid vaccine, and it is considered that vaccination will prove of even greater value in the case of cholera than it is in that of typhoid

A model of the restored skeleton of the horned dinosaur *Triceratops prorsus*, duplicated from one in the U S National Museum at Washington has just been set up in the reptile gallery in the Natural History Museum The original bones upon which the restoration is based were obtained from the Laramie beds (Upper Cretaceous) of Converse County, Wyoming Another addition to the collection of very considerable interest is a specimen of the slughi (or gazelle-hound) of the eastern deserts, the gift of the Hon Florence Amherst The special interest attaching to these dogs (also known as Syrian or Persian greyhounds) is that they belong to the same type as one represented in the tombs of Beni Hasan, and are thus the oldest breed in existence The best strains are in the possession of the Bedouin chiefs, from one of whom the specimen presented by Miss Amherst was obtained

Considerable interest attaches to the exhibition in the entrance hall of the Natural History Museum of a specimen of the tile-fish, *Lopholatilus chamaeleonticeps*, a species remarkable, not only for its brilliant coloration—perhaps unequalled by any other non-tropical fish—but for its curious history The species first made its appearance off No Man's Land, Massachusetts, in 1879, when a specimen was taken in deep water on a cod-line. Soon after it could be taken in abundance with the same kind of apparatus, a catch of some 250 lb of fish (ranging individually from 10 lb to 40 lb) in the course of a couple of hours or less being not uncommon This raised the hopes of fishermen, and in the U S Fishing Report for 1881 it was stated that "there is every reason to believe that the tile-fish will rank among the most important food-fishes of the United States" About the time (1882) that New English fishermen were getting into the swing of the fishing the tile-fish, owing to ice in the Atlantic, disappeared as suddenly as it came, and it is only during the last fifteen years that it has re-visited the American Atlantic coast, where it can now be taken at a depth of about seventy fathoms

The commission appointed for the investigation of Mediterranean fever has issued part v of its report Staff-Surgeon I A Shaw, R N, shows by experiments on monkeys that infection is possible through the eyes, nose and digestive tract by means of infected dust and food and through scratches and wounds by the urine of patients The possibility of infection by unlimited contact is also demonstrated The same investigator shows that the *M melitensis* produces little toxin, and he has failed to obtain a curative serum of much potency, and experiments by Dr Eyre confirm the latter A preventive vaccine was prepared which seemed to possess considerable immunising powers Major Horrocks R A M C discusses the occurrence of Mediterranean fever in Gibraltar, and shows that its incidence there, as in Malta, is probably largely dependent on goats Dr Eyre contributes a bibliography of the disease from 1897 to 1907

Among the botanical papers included in the Proceedings of the Indiana Academy of Science 1905, Mr W J Young communicates an account of the embryology of *Melilotus alba*, stating that the megaspore mother-cell forms the embryo sac without undergoing division, and that a portion of the endosperm functions as a haustorium Mr G W Wilson enumerates the rust fungi with host plants recorded from Hamilton and Marion counties species of Dicæoma attacking cereals, and *Gymnoconia interstitialis* infesting the blackberry bushes, were the most injurious A description of the Leesburg Swamp and the plant associations occurring there is furnished by Mr W Scott

An account of experiments to determine the effect of stimulating organisms with different light rays is communicated by Prof L Hertel to *Naturwissenschaftliche Wochenschrift* (February 10) Two contingencies have to be taken into account, first, allowance must be made for the disparity in the intensity of the rays, and, secondly, the effect of stimulation will vary with the absorbent capacity of the organism for rays of varying wave-length When a method was applied for equalising the intensity of the different rays, the physiological effect was found to decrease from the red to the blue rays, but since the absorption of the rays by living tissue also varied in the same way the conclusion is evolved that the effect of light does not vary with the wave-length

A second paper on *Termes gestroi*, the white ant that is becoming a pest of considerable importance to the Hevea rubber trees in Tenasserim, is contributed by Mr E P Stebbing to the *Indian Forester* (January) The curious accumulations of rubber in the nests have given rise to some discussion The explanation put forward by the

discoverer, that the termites are concerned with these accumulations, has not received acceptance, and it has been suggested that they are due to natural exudation. Meantime, analysis has shown that the rubber is purer than the best ordinary latex, and thus the matter stands. On the subject of fire in teak forests, Mr. H. Rodger presents a note accompanied by illustrations representing probable stages in the destruction of the teak trees.

THE fifth supplement to the first volume of the *Philippine Journal of Science* is appropriated to an enumeration of the Philippine grasses. The author has revised the lists of Blanco, F. Villar, and other previous compilers to exclude doubtful species; he has also drawn up short keys for the identification of tribes, genera, and species. With regard to geographical distribution, one-fifth of the species is endemic, including the monotypic genus *Garnotiella philippinensis*; there is a pronounced affinity with the grasses of the Malayan and Indo-Malayan regions, and a fair sprinkling of Australian types. The determination of the bamboos is uncertain, but the author records a new species of Gigantochloa.

DISCUSSING the mechanical development of the German iron industry in a copiously illustrated article in the *Engineering Magazine* (vol. xxxii., No. 6), Mr. J. H. Cuntz shows that the three important factors which now make for economy are by-product coking, the utilisation of furnace gases in the gas engine, and advanced practice in electric driving of winding and rolling-mill engines.

THE bridge at the Victoria Falls of the River Zambezi was described in detail by Mr. G. A. Hobson in a paper read before the Institution of Civil Engineers on March 19. Several types of bridges were considered, but the nature of the situation made it obvious that a two-hinged spandrel braced arch was the one that most completely answered the requirements of the case. The bridge consists of three spans. The end span, on the left bank, is 62½ feet, and the other 87½ feet, while the central span is 500 feet between the centres of the bearings, with a rise of 90 feet. The entire bridge, with the exception of the main bearings, weighs 1500 tons. The engineering interest which attaches to the execution of this work is due in a large measure to the remoteness of the site. The question of erection was considered of primary importance, and every detail was devised to simplify the procedure.

THE admirable work that is being done by the corps of mining engineers in investigating the mineral resources of Peru is clearly shown in the numbers of the *Boletin* of that body recently received. In No. 41 Mr. M. A. Denegri gives a report on the mineral production of Peru in 1905. The production included 75,338 tons of coal, 49,700 tons of petroleum, and considerable quantities of gold, silver, copper, lead, bismuth, nickel, mercury, salt, and borates. Excellently reproduced photographs accompanying the report indicate that in many cases the mines are well equipped. In No. 44 Mr. Carlos E. Velarde describes the mineral district of Huancavelica. The copper and silver veins are of considerable importance, and the Santo Domingo colliery furnishes an ample supply of coal for steam raising, whilst coke for smelting purposes can be abundantly obtained from the coal of the Oyon collieries, thirty miles distant from Huancavelica. In No. 45 Mr. G. I. Adams deals at length with the water supply of the provinces of Arequipa, Moquegua, and Tacna. Lastly, in No. 46 Mr. F. M. Santolalla describes the mineral resources of the province of Santiago de Chuco. The district is one of the richest in Peru, and its mining industry has a great future in store when better means of transport are provided by the projected extension of the railway from Menocucho to Salpo. The deposits existing in the province may be divided into the metalliferous veins in eruptive rocks, veins in sedimentary rocks, and the coal seams of Callacuyan, Chasamuday, Ilaray, Hospital, and Angasmarca, all of which form part of the same coalfield.

THE admirable paper on petrol motor-omnibuses, read by Mr. W. Worby Beaumont before the Institution of Mechanical Engineers on March 15, forms a valuable contribution to the history of engineering, for there are few examples of rapid growth from the experimental stage to that of widespread practical importance so remarkable as that of the motor omnibus. There is no example so instructive in possibilities as the adaptation of the high-speed, high-power, light-weight petrol prime-mover to the heavy work of the operation of the motor omnibus on common roads. Barely four years have passed since the first petrol-propelled motor-omnibus may be said to have been regularly worked in public service in England, and within the last two years the number in London has increased from a few small vehicles to 795 in actual commission. These are carrying about 185 million passengers per year, and run from 90 to 120 miles per day, or 30,000 to 40,000 miles a year. There is great similarity in external design, but in the details of the mechanism and in the arrangement of the underframes there are considerable differences, which are clearly described by Mr. Beaumont and elucidated by the numerous excellent drawings to scale accompanying his paper. No standardisation in motor-omnibus construction can be expected for some time. The extraordinary mileage has accumulated much experience in a short time, but it has been very costly, and it must be admitted that, even with the finest material ever placed in the hands of the engineer, larger dimensions and greater surfaces are required to contend with the severe work of the present double-deck omnibus. Improvement may be looked for in the introduction of twenty-six passenger in place of the present thirty-four passenger vehicles. Then the weight of an omnibus may be materially reduced, and fuel and oil consumption and wear and tear also reduced, which, with a general observance of the legal speed-limit, will together add to the life and commercial efficiency of an omnibus. It is interesting to note that the cost of working a petrol motor-omnibus running 100 miles per day for 280 days per year may now be put as 9.56*d.* per mile, including depreciation at 20 per cent., while the average receipts per motor-omnibus mile in London exceed 13*d.*

WE have received from Washington a copy of the annual report of the Board of Regents of the Smithsonian Institution for the year ending June 30, 1905, together with a report of Mr. Richard Rathbun, the then acting secretary of the institution, for the year ending on June 30 last. Mr. Rathbun gives an account of the numerous activities of the institution during the year under review, and is able to record satisfactory progress. The general appendix of the regents' report contains as usual an admirable selection of papers by men of science of many nationalities, designed to furnish brief accounts of scientific discovery in particular directions. Among these papers we notice Sir William White's Friday evening address to the Royal Institution, on submarine navigation; Mr. G. T. Beilby's presidential address to the chemical section of the British Association at its South African meeting, on gold

in science and industry, Sir Harry Johnston's paper to the Royal Geographical Society, on Liberia; as well as other contributions by British workers in science The fine illustrations add greatly to the interest of the volume

A THIRD edition of "A Text-book of Plant Diseases caused by Cryptogamic Parasites," by Mr George Massee, principal assistant in the department dealing with cryptogams of the Royal Herbarium, Kew, has been published by Messrs Duckworth and Co

VOL IV of the Proceedings of the London Mathematical Society, second series, is now available The volume is published by Mr Francis Hodgson Among its contents may be mentioned the records of proceedings at meetings of the society, obituary notices of the late Astronomer Royal of Ireland, Mr C J Joly, F R S, and the late Mr Robert Rawson, sometime headmaster of the Dockyard School, Portsmouth, papers published in the Proceedings from November, 1905, to November, 1906, and several useful indexes Abstracts of papers brought before the society appear regularly among our reports of scientific societies and academies

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN APRIL —

April 3	5h 48m to 8h 55m	Transit of Jupiter's Sat. III (Ganymede)
7	16h 18m to 17h 1m	Moon occults γ Capricorni (mag 3 8)
10	9h 55m to 13h 2m.	Transit of Jupiter's Sat III (Ganymede)
13	11h 0m	Vesta in conjunction with the Moon (Vesta 0° 24′ N)
,,	12h 0m	Minimum of Algol (β Persei)
14	16h 0m	Mercury at greatest elongation (27° 36′ W)
16,	8h 49m	Minimum of Algol (β Persei)
18	6h 57m	Jupiter in conjunction with the Moon
20–22		Epoch of Lyrid meteor shower. Radiant 271° + 33°
21	2h 41m	Venus and Saturn in conjunction (Venus 0° 38′ N)
,,		Venus Illuminated portion of disc = 0 773
30.	15h 38m to 16h 50m	Moon occults ξ Ophiuchi (mag 4 5)

COMET 1907*a* (GIACOBINI) —No further observations of this comet have yet been received, but the elements and daily ephemeris computed by Herr M Ebell appear in No 4161 of the *Astronomische Nachrichten* (March 13), the latter extending to March 31 An extract is given below —

Ephemeris 12h (M T Berlin)

1907	α (true) h m	δ (true)	log r	log Δ	Brightness
March 27	6 27 4	− 3 34 3	0 3119	0 2474	0 67
29	6 24 9	2 16 4			
31	6 22 7	− 1 2 3	0 3122	0 2682	0 61

OBSERVATION OF COMET 1905 IV —A telegram from the Kiel Centralstelle announces a further observation of comet 1905 IV by Dr Kopff at the Königstuhl Observatory on March 21 The position of the comet at 14h 45 8m (Königstuhl M T) was

R A = 14h 58 6m, dec = 21° 18′ S,

and the magnitude was estimated to be 13 8

The above position lies in the constellation Libra, and is above the horizon from about 11 p m to 6 a m

This comet was first discovered, as 1906*b*, by Dr Kopff at Heidelberg on March 3, 1906, and was observed until June, 1906, the perihelion passage occurred on October 18, 1905 The orbit is remarkable for its great perihelion distance (3 3 R), which has only been exceeded by that of the comet of 1729 The motion is probably parabolic, although an elliptic orbit, having a period of 1153 years, has been suggested

STANDARD STELLAR MAGNITUDES —In order that astronomers may have a ready means of reducing their magnitude observations to a uniform scale, Prof Pickering publishes, in Circular No 125 of the Harvard College Observatory the positions and carefully determined photometric magnitudes of a selected sequence of stars in the region of the North Pole To determine the magnitudes of other stars the following method is suggested —Two photographs are taken, one of the polar region, the other of the region to be investigated, and on the former the standard stars, on the latter the stars the magnitudes of which are to be determined, are marked Then on a night when the atmospheric conditions are good and constant, and at a time when the second region is at about the same altitude as the pole, a third plate is successively exposed for exactly the same time on each of the two regions

Thus on the third plate the observer has the standard and unknown star images on the same plate taken under exactly the same conditions, and may recognise them by superposing, in turn, the two negatives first secured and marking off the required images These may then be compared for magnitude, and the results reduced to a standard scale by means of Prof Pickering's standard list

THE SPECTRUM AND RADIAL VELOCITY OF MIRA —In No 1, vol i, of the Journal of the Royal Astronomical Society of Canada, Mr J S Plaskett, of the Dominion Observatory, publishes the results of a spectrographic investigation of Mira during the most recent maximum The spectra were obtained with a three-prism Brashear universal spectroscope giving a linear dispersion at Hγ of 18 6 tenth-metres per millimetre, and having a resolving power of 40 000 The results obtained by measuring two plates are in good agreement with one another and with the results obtained by Prof Campbell and Mr Stebbins For the absorption lines a radial velocity of +65 6 km, reduced to the sun, was obtained, and as this is practically the value obtained by the other two observers mentioned, in 1897 and 1902 it appears that the receding motion of Mira in the line of sight is constant. The velocity, as determined from the bright hydrogen lines, is some 15 km less and Mr Plaskett suggests that this difference is probably due to some abnormal conditions of pressure, temperature, or electrical state in the atmosphere of the star

The present spectrograms show that titanium is undoubtedly represented in the spectrum of Mira, a point considered doubtful by Stebbins in 1902, and that the magnesium line at λ 4571, bright in 1902, is now represented by a normal absorption line Hβ is fairly strong as a bright line, but Hϵ cannot be seen on these spectra

TWO RAPIDLY-CHANGING VARIABLE STARS —In No 5 of the *Comptes rendus* M J Baillaud announced the discovery of two new variable stars of which the light changes were so rapid as to be shown on plates taken at the Paris Observatory with three successive exposures at intervals of half an hour During the period of observation one of these stars changed from magnitude 14 5 to magnitude 12 7 the other changed from 14 5 to 13 6. As there are not likely to be many photographic images of these faint objects they have been looked for on the Harvard photographs, and in Circular No 126 Prof Pickering publishes the information that has been gathered from thirteen plates

A NEW ASTRONOMICAL JOURNAL —We are pleased to be able to record that, with an increased grant from the Dominion Government, the Royal Astronomical Society of Canada has commenced the publication of a bi-monthly journal recording the proceedings of the society The first number (January and February, 1907) contains information regarding the society and several very interesting papers Among the latter may be mentioned two papers by Mr Stupart on magnetic storms and auroræ, the president's address on the astronomical work of 1906, and a paper by Mr Plaskett on the spectrum of Mira, referred to above

MODERN VIEWS OF THE ETHER

Introduction

IN putting into print once more the book called "Modern Views of Electricity," my object is to recall attention to the ethereal aspect of affairs, and to assist in the combination of those ideas with the comparatively recent notion of electrons on the strength of which such great advances have been made There are several additions to the book, and especially there is a concluding chapter which, since the other portions of the original book appeared in the columns of NATURE, may likewise be allowed so to appear It will be observed that, on the basis of a consistent working hypothesis therein, an attempt is made to estimate the absolute value of the two ethereal constants—a thing which I have for many years sought to do It will also be seen that, from the point of view adopted, the density of the ether comes out, not merely greater than platinum, as had several times been surmised, but very much greater in fact, something comparable to a billion times the density of water, and its intrinsic constitutional energy is correspondingly enormous

There is nothing paradoxical, nor, so far as I can see, improbable, about these figures Matter is an excessively porous or gossamer-like structure, and the inertia of matter must be a mere residual fraction of the inertia of the continuous incompressible complex fluid, of which it is hypothetically composed, and in which it moves

The following is the chapter referred to —

CONCLUDING CHAPTER OR SUMMARY

Structure of the Ether

What, then, is the conclusion of the whole matter, so far as a conclusion is possible at present?

The material universe seems to consist of a perfectly continuous incompressible and inextensible medium, filling all space without interstices or breach of continuity,—not of a molecular or discrete structure, and as a whole completely at rest as frictionless moreover, and unresisting to all ordinary motion of what we call matter through it, as is the mathematical conception—a perfect fluid But in spite of immobility as a whole, it possesses that property of "rigidity," or elastic resilience to "shear" which is characteristic of what we ordinarily call a solid, wherefore it would appear that it must be, throughout, in such a state of excessively fine-grained turbulent motion as would confer this property upon it And the resilience is so complete and instantaneous, without any delay or permanent set, that the elasticity must be described as "perfect" It is the gyrostatic kind of elasticity discovered dynamically and applied ethereally by Lord Kelvin, whereby a perfect fluid can kinetically acquire some of the properties of a perfect solid

It is well known that every solid possesses two kinds of elasticity—elasticity of bulk and elasticity of shape The first, or volume elasticity may also be called "the incompressibility" and is common to all forms of matter—fluid as well as solid In the case of the ether, however, the value of this quantity appears to be infinite it is, at any rate, greater than we have as yet been able to appreciate by specially directed experiments—meaning especially the Cavendish experiment referred to in §§ 4 and 14A The elasticity of figure, or shape-elasticity is only possessed by solids and is technically called "rigidity", it is small in the case of india rubber great in the case of steel or glass it is the property on which spiral springs and torsion-balances depend The two kinds of elasticity are quite independent of each other—quite independent also of anything akin to viscosity, which in the case of the ether appears to be zero

Now something analogous to shape-elasticity the ether possesses It does not possess ordinary mechanical rigidity, because that is an affair of molecules but it possesses something which may be called an electric rigidity, or electromotive elasticity It is identical with the electromotive elasticity of a dielectric—it is the property which causes recoil after charge and it has been denoted by $4\pi/\kappa$, where κ is the absolute Faraday's dielectric constant or specific inductive capacity for free space

The property thus analogous to rigidity, or shape-elasticity, is accompanied by another property, akin to inertia This is the property to which magnetism is due, it is a magnetic inertia, to pair with electric rigidity, and it has been denoted throughout by $4\pi\mu$, where μ is the absolute magnetic permeability of free space The self-induction of quasi-inertia associated with every electric current, of which $4\pi\mu$ is the non-geometrical and essential factor, is explicable, up to a point, as due to the magnetic field excited by electric motion, but it would seem as if ultimately it must necessarily be dependent on an unexplained and fundamental kind of inertia possessed by the ether itself, so that the ether may be said to have a certain density, or mass per unit volume,—something at least so like ordinary material specific-gravity or density that we have to call it by the same name

By reason of these two properties—electric elasticity and magnetic density—transverse electromagnetic waves are transmitted through and by the ether, at a perfectly definite and known speed This speed of wave propagation is far greater than any we are accustomed to in connection with matter, and if ever the motion of matter can be made to approach this speed, it must encounter a reaction or impedance or opposition to further acceleration, which ultimately, in the limit, amounts to a practically infinite obstruction, at the actual critical speed

This obstruction is not of the nature of friction,—it is not resistance proportional to the velocity or in any way dependent on the velocity it solely opposes acceleration, and is of the nature of impedance or inertia

The fact of inertia enables an oscillatory wave-process to go on in the ether, and endows those oscillations with a particular kind of alternating kinetic, as well as with potential, energy

The energy of strained or distorted ether is always potential energy, and is all the potential energy there is but accessible or convertible kinetic energy is usually only possessed by those individualised and discriminated regions or ethereal structures, which possess the power of locomotion, and which in their aggregate appeal to our senses as "matter"

During the passage of waves, the ethereal structure is sheared to and fro not with any movement as a whole, but with equal opposite movement of two aspects, or elements, or conditions, of its structure such shear being equivalent to what is called an electric displacement, and being subject to a restoring force accurately proportional to that displacement

This elasticity is "perfect" in free space, apart from matter, until a critical shear, of unknown value, is reached If strained beyond that, it may be supposed that a separation, or dislocation, or decomposition, of the ether into two components or constituents would occur,—constituents generated, as it were by means of the shear, and probably not existing, as such, in the unperturbed ether One of these components we call positive, and the other negative, electricity Once formed they do not disappear again they may combine—or approach each other so closely that they neutralise each other's effects at a distance, but they are still readily separable by electromotive force They do not combine in the sense of destroying each other—they do not re-form the original substance out of which they were produced

The negative electricity, when separated, is freely mobile and easily isolated it is what we experience as an electron The positive constituent does not appear thus in an isolated manner, but is only known to exist in a mass as if matted together and associated with an indistinguishable and inseparable aggregate of charges—opposite charges apparently in combination, going about as a whole Some of these aggregates may unite into larger ones others when too large may split up into smaller ones and so finally a set of sub permanent stable aggregates are formed, which we recognise as the atoms of the so-called "elements" of matter each with its appropriate degree of stability

These masses or aggregates may temporarily acquire or may lose, one or more of the free electrons and by thus becoming amenable to electrical or chemical attractions and repulsions constitute what we call "ions," so long as the unbalanced or electrified condition lasts

Massiveness of the Ether

Each electron, moving like a sphere through a fluid, has a certain mass associated with it, dependent on its size, and, at very high speeds, on its velocity also

Now how shall that mass be treated?

Shall we deal with it on the analogy of a sphere moving through a perfect irrotational liquid, without examining into details any further?

Or shall we consider it as generating circular lines of magnetic induction by its movement, by reason of the rotational properties of the ether, and attribute all its inertia to the magnetic whirl thus caused round its path treating the whirl as an actual circulation of fluid excited by the locomotion?

Both methods may be adopted, to see whether they will agree

Now treating it by the first method, and considering the electron merely as a sphere moving through a perfect liquid, its behaviour is exactly as if its mass were increased by half that of the fluid displaced and the surrounding fluid were annihilated It has been argued in the book, from the result of the Cavendish surface-charge experiment, and from the phenomena of gravitation, that the ether is incompressible, to a high degree of exactness, and accordingly the density of fluid inside and outside an electron must be the same So that, treating it in this simplest fashion, the resultant inertia is half as great again as that of the volume of fluid corresponding to the electron that is to say, is $2\pi\rho a^3$, where ρ is the uniform density If it is of some other shape than a sphere, then the numerical part is modified, but remains of the same order of magnitude

Now treat it by the other, or magnetic whirl, method

Let a spherical electron e of radius a be flying at speed u, so that the magnetic field at any point $r\theta$, outside, is

$$H=\frac{eu\sin\theta}{r^2},$$

and the energy per unit volume everywhere is $\mu H^2/8\pi$

It has been shown by Lord Kelvin, Mr Heaviside, G F FitzGerald, and Prof Larmor, that a magnetic field may be thought of, hypothetically, as a circulation of fluid along the lines of magnetic induction—which are always closed curves—at some unknown velocity w

Consider the energy per unit volume anywhere, it can be represented by the equivalent expressions

$$\tfrac{1}{2}\rho w^2=\frac{\mu H^2}{8\pi}=\frac{\mu}{8\pi}\frac{e^2u^2\sin^2\theta}{r^4},$$

wherefore

$$\frac{w}{u}=\sqrt{\left(\frac{\mu}{4\pi\rho}\right)}\frac{e\sin\theta}{r^2},$$

On the cog-wheel analogy the highest velocity will be that in contact with the moving charge, and there is some reason to suppose that the maximum velocity w at the equator of the moving sphere may be equal to the speed u Elsewhere it will decrease with the inverse square of the distance just as H decreases

But without any hypothesis, if there be a circulation at all its velocity must be a maximum at the equator of the sphere where $r=0$ and $\theta=90$, so, calling this w_0,

$$\frac{w_0}{u}=\sqrt{\frac{\mu}{4\pi\rho}}\cdot\frac{e}{a^2},$$

and

$$\frac{w}{w_0}=\frac{a^2\sin\theta}{r^2},$$

and therefore the major part of the circulation is limited to a region not far removed from the surface of the electron

The energy of this motion is

$$\tfrac{1}{2}\rho\int_0^\pi\int_a^\infty w^2 \quad 2\pi r\sin\theta \quad rd\theta \quad dr,$$

or substituting the above value of w the energy comes out equal to $\frac{4}{3}\pi\rho a^3 w_0^2$

Comparing this with a mass moving with speed u,

$$m=\frac{8}{3}\pi\rho a^3\left(\frac{w_0}{u}\right)^2$$

This agrees with the simple hydrodynamic estimate of effective inertia, if $w_0=\frac{1}{2}\sqrt{3}u$, that is to say, if the whirl in contact with the equator of the sphere is of the same order of magnitude as the longitudinal rack-motion or cog-wheel spin at the same place

Now for the real relation between w_0 and u we must make a hypothesis If the two are considered equal, the effectively disturbed mass comes out as twice that of the bulk of the electron If w_0 is much smaller than u, then the mass of the effectively disturbed fluid is much less even than the bulk of an electron, and in that case the estimate of the fluid-density ρ must be exaggerated enormously, in order to supply the required energy It is difficult to suppose the equatorial circulation w_0 *greater* than u, since it is generated by it, and it is not unreasonable to treat them both as of the same order of magnitude So, taking them as equal,

$$e=a^2\sqrt{\frac{4\pi\rho}{\mu}}$$

and $m=$ twice the spherical mass

Hence all the estimates of the effective inertia of an electron are of the same order of magnitude, being all comparable with that of a mass of ether equal to the electron in bulk

This would also be the conclusion drawn, if, instead of integrating the magnetic energy from a to infinity, we integrated from a to a larger radius b, or say na, the inertia would then come out

$$\tfrac{2}{3}\mu e^2\left(\frac{1}{b}-\frac{1}{a}\right) \text{ or } \frac{2(n-1)}{3n}\frac{\mu e^2}{a},$$

and be still of the same order of magnitude for all reasonable values of n, the reason being that all the effective disturbance is concentrated in the neighbourhood of the charge

Now the linear dimension of an electron is 10^{-13} centimetre diameter, and its mass is of the order 10^{-27} gram, being about the 1/700th part of the atom of hydrogen Consequently, if its mass were due to its contents, the density of its material must be of the order

$$10^{-27}\div 10^{-39}=10^{12} \text{ grams per cubic centimetre}$$

This, truly, is enormous, but any reduction in the estimate of the circulation speed, below that of an electron, would only go to increase it, and since electrons move sometimes at a speed not far below that of light we can not be accused of underestimating the probable velocity of magnetic spin by treating it as of the same order of magnitude, at the bounding surface of the electron a relation suggested, though not enforced, by the cog-wheel and gyrostat analogy

Incidentally, we may notice how enormous is the magnetic field surrounding the equator of an electron moving along an axis with, say, one-thirtieth the speed of light it amounts to 10^{15} C G S lines per sq centimetre And the magnetic energy there is correspondingly enormous, being 4×10^{28} ergs per c c At the velocity of light it would equal the constitutional energy of the ether itself

Value of the Ethereal Constants

It has been argued throughout the book that the ethereal density is what we know in magnetism as $4\pi\mu$, wherefore an approximate estimate of the absolute value of the magnetic constant μ for free space, on this view, is 10^{11} grams per c c

Using the value $4\pi\mu=\rho$, we get for the charge of an electron

$$e=4\pi a^2,$$

or comparable to its superficies.

The speed with which waves travel through the medium is the square root of 10^{21} C G S, consequently the elasticity of the ether must be of the order 10^{33} dynes per square centimetre, which is what in static electricity we denote by $4\pi/\kappa$ Wherefore an approximate estimate of

the absolute value of Faraday's dielectric constant κ, for free space, is 10^{-33} cubic centimetre per erg

In other words, the intrinsic energy of constitutional motion of the ether, to which its rigidity is due, is of the order 10^{33} ergs or 10^{26} Joules per cubic centimetre—about a hundred foot lbs per atomic volume, which is equivalent to the output of a million horse-power working for forty million years, in every cubic millimetre of space It can otherwise be expressed as the energy of a thousand tons per cubic millimetre, moving with the velocity of light, but of course the motion really contemplated is all internal and circulatory

Transmission of Waves

Wherever electrons and atoms exist, they modify the ether in their immediate neighbourhood, so that waves passing through a portion of space containing them are affected by their presence, as if the ether were more or less loaded by them, because the electric displacements which go on in the unseparated and still perfectly united constituents of free ether are also shared to some extent by the separated peculiarities especially by those of the electrons which are not too embedded in or surrounded by a positive charge—for instance, like a nucleus in a shell These might be inert and without influence on the light, except as small fixed mechanical obstructions but all those charges which possess externally-reaching lines of force must share in the motion of the waves, without having the requisite amount of resilience to compensate for their inertia consequently they, to that extent, constitute a retarding, and either an absorbing or a reflecting agency

Furthermore their motions of vibration and rotation during the epochs of acceleration, however caused encounter the inertia of the medium, and thereby excite waves in it—waves of oscillatory electric displacement with magnetic concomitant—and this electromagnetic radiation is transmitted out into space but it is insignificant in amount unless the acceleration is violent It is proportional to the square of the acceleration

The positive and negative constituents, when they combine or cohere do not destroy each other and revert into plain ether again, on the contrary, they retain their individuality and persist in either a combined or separate state We do not know how to produce or to destroy these peculiarities, and though atoms of matter are composed of them and though all electrical phenomena and the excitation of radiation are due to their presence and behaviour it is no more and perhaps not much less correct to say that the main bulk of the ether is composed of them than it is to say that actual sodium and chlorine exist in undissociated common salt These elements only make their appearance when the original substance is decomposed But certainly matter can be dissociated with extreme ease, whereas the dissociation of ether is unknown and hypothetical, save as represented by its apparent results

Nevertheless it must be the case that the slight, almost infinitesimal, shear which goes on in a light wave, is of the nature of incipient and temporary electric separation and all electromotive force *tends* to drive one constituent in one direction and the other in the other thus beginning that individualisation or separate manifestation of the two ingredients, without a knowledge of which the original fluid would have appeared to be of a perfectly uniform and homogeneous character

It is quite possible that the actually double aspect of ether is not only manifested but really generated by an electromotive force applied to it, just as the elastic recoil is so generated It appears possible that a sufficiently violent E M F applied to the ether, by some method unknown to us at present, must be the kind of influence necessary to shear it beyond the critical value and leave its components permanently distinct such constituents being opposite electric charges which when once thoroughly separated only combine to form matter, and do not recoil into ordinary ether again

Hypothetical Longitudinal Stress

Every attempt at separation of this kind, even if no stronger than exists in ordinary light, seems to be accompanied by a slight longitudinal force at right angles both to the displacement and to the orbital axis of the excursion —a force which is known as the normal pressure of light, or Maxwell's pressure, perpendicular to an advancing wave-front the inertia of the constantly encroached upon region of free ether having the effect of momentum

If the disturbance could be made so extreme as to result in permanent dislocation this pressure might leave behind it, as permanent residue, a longitudinal pressure, extending throughout space inversely as the distance, whereby all the dislocated material would thereafter be urged together with a force which we know as gravitation, proportional in any piece of matter to the number of dislocated centres which go to compose it, and therefore proportional to its mass irrespective of secondary accidents of a physical or chemical constitution

Amplitude of Light Wave

If a is the amplitude of shear during the passage of a wave of light, and if u is the maximum velocity of recovery, then

$$\frac{u}{v} = 2\pi\frac{a}{\lambda},$$

where v is the velocity of light and λ the wave-length The total energy per unit volume is $\frac{1}{2}\rho u^2$ where ρ is the density of the medium, for this represents twice the average kinetic energy, and of this quantity one half is really kinetic, the other half potential

Now direct thermal measurements, such as those conducted by Pouillet, give us the energy of sunlight near the earth 4×10^{-5} erg per c c and consequently, in the region of intense light near the solar surface the energy of radiation must be about 2 ergs per cubic centimetre There may be more intense light than this, but this is the most intense we know of so it is instructive to consider the amplitude of the shear corresponding to such violent illumination Let us therefore put $\frac{1}{2}\rho u^2 = 2$ whence

$$u^2 = 4\times10^{-12}$$

It follows therefore, that

$$u/v = \tfrac{2}{3}\times10^{-16}$$

and accordingly the amplitude of the most intense visible light we are acquainted with, is only 10^{-17} of a wave-length The maximum strain is 2π times this fraction, and so the tangential stress thus called out in the medium its rigidity being 10^{33}, may be estimated as comparable with 10^{17} dynes per square centimetre or 10^{11} atmospheres

The ordinary electrostatic unit of charge on this estimate of ethereal elasticity becomes 10^{-16} square centimetre or the superficial dimension of an atom This also corresponds with the estimate above that the electronic charge is equal to the superficies of an electron, since one should be 10^{10} times the other

The pressure of light has been represented by Prof Poynting as a travelling momentum like that of a jet of water resulting in a pressure ρcv where c is the velocity of longitudinal motion or circulation in the light beam, and v is the velocity of light Taking the pressure of intensest light as 2 dynes per square centimetre this gives $c = \tfrac{2}{3}10^{-22}$ centimetre per second excessively small therefore, even in that extreme case

Hypothetical Flow along Lines of Magnetic Induction

It has long been a working hypothesis with some mathematical physicists (see, for instance, the ensuing April number of the *Philosophical Magazine*) that there was probably something of the nature of a flow—an ethereal flow—along lines of magnetic induction, and the fact that these are always closed curves in all known circumstances, is in favour of such an idea The energy of the field would then be attributable to the energy of this flow and though it is possible that the flow might be of the nature of components moving in opposite directions the movement is hardly likely to be of this nature since that would correspond with merely an electric current

Fourteen years ago, in 1893, having rather perfect appliances for examining the effect of drift on the velocity of light, I carefully looked for some longitudinal flow along lines of magnetic force, repeating the experiments

still more anxiously when I learnt that something of the kind was seriously suspected by Dr Larmor

Applying a field of 1400 C G S units over a length of light path of about 14 metres in the aggregate, things were so arranged that a drift of 1 foot a second, or about 10^{-9}th of the velocity of light, would have been observed by a fractional shift of micrometrically viewed interference bands, if it had occurred But no effect whatever on the interference bands could be detected, nor was anything observed when—with less perfect vision, in that case, owing to increased difficulties—the air along the field and path of light was replaced by bisulphide of carbon, except that, of course, if plane-polarised light was used, the plane was then rotated by a very large amount Sufficient details of this series of negative experiments will be given in the forthcoming April issue of the *Philosophical Magazine*

The result was to show that if the magnetic energy were to be accounted for in the assumed kinetic fashion, the density of the ether must be very considerable—in fact about 180 times that of water—in order to give the actual energy with a velocity below what could be observed in this way

I have now, however, as described above made a theoretical estimate of the density of the ether—arriving at the tentative conclusion that it is of the order 10^{12}—and we can therefore proceed to calculate what velocity of hypothetical ethereal drift is to be expected in any given magnetic field It will come out, of course, exceedingly slow, for, on this view, the electromagnetic unit of field is $\mu^{-\frac{1}{2}}$, which equals 3×10^{-8} centimetre per second, and the velocity to be expected is the 2πth of that

So, for instance, the field inside a solenoid, surrounded by a current of 100 amperes circulating 100 times round every centimetre of it, being $4\pi n_1 C$, will equal 12,000 C G S, which corresponds with a velocity of 0.003 centimetre per second, or about 4 inches an hour In fact, the ampere turns per inch, in any solenoid, measures the speed of magnetic circulation along its axis, no matter what the material of the core may be, in millimicrons per second

When iron is substituted for air the speed is the same, but the ethereal density is virtually increased, by the loading due to the molecular whirls in the iron

It may seem difficult to reconcile this very slow velocity, in any ordinary field, with the great velocity of the very same character already postulated in the immediate neighbourhood of an electron, where it is supposed that the magnetic circulation is equal to, or at any rate of the same order of magnitude as, the locomotion speed—which it is well known may easily be 1/30th of the velocity of light without departing appreciably from the simply calculated inertia But that great speed in the immediate neighbourhood of an electron, can be fully admitted and there is nothing really inconsistent in that with the slow speed observed at any ordinary distance For instance, if close to the equator of a flying electron, the ethereal magnetic speed is 1/30th of the velocity of light, or 10^9 centimetres per second then, at a distance of 1 millimetre away the speed is reduced to 10^{-24}th of that value and is therefore even at that small distance, only 10^{-15} centimetre per second, or 3 millimicrons per thousand years

The speed at the axis of a solenoid is, of course, far greater than that, because of the immense number of electrons in any ordinary current surrounding it, but, in order to get up a drift-velocity of 1 centimetre per second in a solenoid a thousand amperes would have to circulate three thousand times round every centimetre of it, which seems hardly practicable

The optical arrangements in my experiment above spoken of, could doubtless be improved sufficiently to show an ether drift of 1 centimetre per second, but I do not see how to produce a field of the required intensity to give even this leisurely flow Such a field would have to be about four million C G S units, and must exist throughout a great length of air

The experimental verification of the above theoretical estimate of ethereal density seems therefore to be beyond the reach of this form of experiment Nevertheless, I feel reasonably convinced that there is a justification for assuming the ether to have properties such as can only for the present be represented, in analogy with the properties of matter, by saying that its behaviour consistently indicates something typified by its possession of an immense elasticity or rigidity, 10^{33} dynes per square centimetre, caused by its intrinsic constitutional energy; combined with a property analogous to, and resulting in, material inertia, and typified by attributing to it a density of the order 10^{12} grams per cubic centimetre The ethereal property, here called elasticity, is certainly the source and origin of every kind of material elasticity and potential energy, for the only real static effect producible in the particles of matter is a change in their arrangement or configuration All stress must exist really in the ether

Although the experimental methods so far suggested have proved themselves unable to test the magnitudes involved in these high values, some other method of inquiry may be suggested, and the theory may yet be brought to the test of experiment OLIVER LODGE

THE INSTITUTION OF NAVAL ARCHITECTS

THE annual spring meeting of the Institution of Naval Architects was held last week at the Society of Arts, commencing Wednesday, March 20, and being continued over the two following days Fourteen papers were read and discussed, some of them at considerable length, while Lord Glasgow's presidential address, the report of the council, and other necessary business received due attention

The first paper taken was a contribution by Mr James McKechnie, of Barrow, the subject being the influence of machinery on the gun-power of the modern warship This paper was full of information, but perhaps the most interesting part was that in which the author compared the elements of design of three imaginary battleships, propelled respectively by steam, gas, or oil engines It is somewhat startling to find the chief engineer of one of our most powerful shipbuilding and engineering companies—and one, too, so largely engaged in the production of war material—should think gas or oil engines as propulsive agents for the largest warships, sufficiently within the possibilities of the near future as to make it the subject of a paper before this important institution, it is prophetic of still vaster changes in store than even the transition from shell boilers to water-tube boilers, and from reciprocating engines to the steam turbine Mr McKechnie, however, intimated during the discussion on his paper that his company, Vickers, Sons and Maxim, was quite prepared to build a warship with gas-producers in place of boilers, and gas engines in place of steam engines, if any Government had the courage to give them an order It would seem almost that steam's unconquerable arm is likely to have its supremacy challenged even in that field where we have hitherto held it to be most secure

Mr McKechnie takes for his comparison the designs of three battleships, each of 16,000 horse-power The one propelled by steam would have machinery that would develop 10.1 horse-power per ton weight of machinery, the gas-driven machinery would give 14.48 horse-power per ton, whilst the oil engines and machinery would give off 21.33 horse-power per ton Probably an oil-engined battleship may be considered outside the bounds of practical engineering application until oil fuel becomes far more plentiful than there appears to be any prospect of it being at present, waiting, of course, that gloomy but undefined era when the coal supplies of the world are exhausted If, however, we confine ourselves to coal fuel, it is certainly a tempting offer which the engineer offers to the naval architect, this increase of nearly 50 per cent in the power developed on a given weight There are, however, other inducements With the steam engine the area occupied by machinery per unit of power is 0.453 square foot, whilst of the gas engine but 0.336 square foot is needed for each horse-power developed That also is a very substantial gain in a battleship, where every inch of space is so costly to produce and so urgently needed

The third chief consideration Mr McKechnie brings forward is fuel economy Steaming at full power, the coal

burnt would be 1·6 lb per indicated horse-power with one ship, whilst the sister vessel would be "gassing" (we shall have to become reconciled to the objectionable term) with a consumption of 1 lb of coal per indicated horse-power per hour. Here is a saving of more than 50 per cent. in weight of coal carried, bunker space, time of coaling, and other subsidiary matters, amongst them money cost. At lower powers the figures bear approximately the same ratio.

These are enormous strategical advantages, but the tactical benefits offered are hardly less pronounced. By means of profile views the author showed the gun emplacements of the two ships. With the usual two-chimney arrangement of the steam ship, there are four 12-inch guns placed in pairs in two barbettes at the ends of the battery as is usual. These have arcs of training, a few degrees before or abaft the beam respectively, whilst the weapons of a lighter nature can only fire on their respective broadsides. When we turn to the ship without boilers—the gas-engine ship—we find the space that would be taken in the other vessel by funnels, uptakes, &c., occupied by three additional barbettes placed *en echelon*, and each containing two 12-inch guns. There are also the two end barbettes with their four guns, as in the steam ship. These six centrally placed guns can be, moreover, trained on either broadside, so that, in an encounter between the steam ship and the gas ship the latter could bring ten 12-inch guns into action as against four of the former vessel, supposing the encounter to be broadside on; or, to put the case another way, the gas ship could fight a steam ship on each broadside, and have a superiority over her enemies of two 12-inch guns. With secondary armament the problem is more complicated, and could hardly be explained without diagrams.

What, it will be asked, are the defects of these qualities? and an answer can only be given by the light of experience—an experience only likely to be gathered by steps. The marine steam engine has been brought to such a state of efficiency that its performance can be practically depended upon; this is not the case with the producer gas engine. There are many things to find out yet, the problem being more complex from the combination of mechanical and chemical sciences that have to be applied. With gas engines afloat—a very different thing from gas engines ashore supplied from a central source—one hears of the explosive mixture failing, from unexplained causes, and the engines stopping without warning, and there are details of working connected with ignition and other points which have yet to be perfected. For much the same reason that many naval engineers prefer hydraulics to electricity for working armaments steam is likely to be preferred to gas for propelling battleships. Which will ultimately survive time will show; in the meantime it may be said Mr. McKechnie has worked out a very strong case for gas.

The remaining paper taken on this day was by Mr. Simon Lake, who dealt with the subject of submarine boats. The type of vessel the author advocates is fairly well known, its most striking characteristic being that it is fitted with wheels so that it can travel along the bottom of the sea. The paper gave an interesting account of some of Mr. Lake's adventures in his ingeniously devised craft.

On the second day of the meeting Mr. W. J. Luke, of Clydebank, read a paper in which details of certain points in the construction of the new big Cunard ship *Lusitania* were set forth. The chief point was the application of high tensile steel in the upper part of the hull structure, a detail of shipbuilding design which possesses definite advantages, seeing that the hogging stresses are more serious than the sagging stresses, and therefore tension is of high importance for the upper member of the girder formed by the hull structure. The evolution of the modern cargo steamer was the subject of a paper by Mr. S. J. P. Thearle, of Lloyd's. It was a contribution that will be of value in the Transactions of the institution for future students of the history of shipbuilding. Cranes for shipbuilding afforded a subject of practical interest for Signor C. Piaggo.

The two papers that were read at the evening meeting of the same day were both of interest and importance. They described two forms of instrument for measuring the power given off by turbines. The author of the first paper was Mr. A. Denny, and of the second Mr. J. H. Gibson. As is well known, the ordinary steam-engine indicator, by which horse-power has been measured since the days of James Watt, is useless for application to turbines, because there is no reciprocating motion with the latter. This has been a serious obstacle in the path of ship designers, but it appears to have been overcome by taking indicators of the torsion of the shafting through which power is conveyed from the turbine to the propeller. In both the instruments described by the authors of the two papers recourse is had to this means, but the method of recording is different. In the Denny and Johnstone torsiometer is an electrical method in which a telephone is used, whilst in Mr. Gibson's instrument recourse is had to a flash of light deflected by a mirror. The details by which these processes are made practical have been worked out in each case with great ingenuity, but it would be difficult to make them clear without illustrations. It may be pointed out, as Lord Glasgow stated at the meeting, that the successful application of these instruments will solve a problem that the elder Froude worked out with much enthusiasm during the later years of his life, though with very partial success. A paper on propeller struts, by Mr. G. Simpson, was of purely professional interest.

One of the most interesting papers of the meeting was Sir William White's contribution on experiments with Dr. Schlick's gyroscopic steadying apparatus. This paper is of such interest that we propose to deal with it separately. Its full comprehension, however, involves a knowledge of the principles set forth in a paper read by Dr. Schlick a few years ago, Sir William having thought it unnecessary to go over the same ground again.

The other papers read were on the approximate formulæ for determining the resistance of ships, by A. W. Johns; on the application of the integraph to ship calculations, by J. G. Johnstone; on the prevention of fire at sea, by Prof. Vivian B. Lewes; on modern floating docks, by Lyonel Clark; and on some phases of the fuel question, by Prof. Vivian B. Lewes.

The institution will hold a summer meeting in Bordeaux towards the end of June.

TICKS AS TRANSMITTERS OF DISEASE.[1]

MANY statements are found in medical works as to the local poisonous effects of tick bites, but these are of small importance compared with the diseases inoculated by ticks. Until a year or so ago ticks were only known to transmit one kind of disease, and this was confined to the lower animals. Of these diseases, "Texas" fever in cattle may be regarded as the type. These diseases, which are met with in cattle, horses, asses, sheep and dogs, are due to parasites which attack the red cells of the blood. The parasites are characterised by their pear shape, and hence were originally called Pyrosoma, but this name has now generally been replaced by Piroplasma, and the infection by these parasites is known as piroplasmosis.

Smith and Kilborne in America, by their classical researches, first established the fact that Texas fever in cattle was transmitted by ticks. We may consider the mode of transmission somewhat more closely. Ticks in their life-history go through the stages of eggs, larva, nymph, and adult. In the case of transmission of malaria by certain Anophelines, we know that the adult mosquito when it has fed on the blood of a malarial patient can transmit the disease again after the lapse of ten days more or less, to a healthy person. Very different, however, is the mode of transmission of piroplasmosis by ticks. Smith and Kilborne showed that Texas fever was transmitted from the sick to the healthy animal, not by adult ticks, but that it was young ticks hatched from the eggs

[1] "Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India." New series No. 23. "The Anatomy and Histology of Ticks." By Capt. S. R. Christophers. Pp. 55+plates. (Calcutta: Office of the Superintendent of Government Printing, 1906.) Price 4s. 6d.
Memoir xxi of the Liverpool School of Tropical Medicine. September 1906. Pp. xiv+118+plates. (London: Williams and Norgate.) Price 7s. 6d. net.

of ticks found on diseased animals that transmitted the infection. The transmission is thus hereditary, and of a transmission of this kind we have no evidence at all in the case of malaria, though it has been stated that this mode of transmission occurs in yellow fever.

The transmission of Piroplasma by ticks is thus peculiar, and when we come to examine the known facts closely the peculiarity increases. Smith and Kilborne, as we have stated, showed that the infection of Texas fever due to *P. bigeminum* was carried by ticks in their larval stage. In the case of *P. canis* producing malignant jaundice in dogs the mode is different. In this case it is not the larva, but the adult tick of the second generation that transmits the disease. This also is the case for red-water of sheep due to *P. ovis*. In the case of piroplasmosis of the horse the mode has not yet been definitely established. Finally, in the case of "African coast fever" in cattle, a disease resembling in some respects "Texas" fever, but due to a different Piroplasma, viz. *P. parvum*, we appear to have a still more complex state of things. The transmission, according to Lounsbury, in the case of the tick (*R. appendiculatus*) is not hereditary, but is transmitted by nymphs which in the larval stage have fed on infected animals and also by adults which in the nymphal stage have fed on infected animals. Hence it is clear that analogy as a guide is almost useless, and it must be determined by actual experiment how in each case the transmission is brought about. Of the actual changes undergone by the Piroplasma in the tick, egg, larva, nymph, as the case may be, we know but little.

Recently, however, Koch described peculiar forms in the stomach of the tick which he considers to represent a cycle of development. Other forms have also been found in the egg, but not so far in the larva or nymph. No doubt research will be in the future directed to these points.

Piroplasmosis is, then, an important set of diseases transmitted by ticks, but, further, they have been recently shown to play a part in the transmission of those minute, slender, corkscrew-like parasites known as Spirochætes. These parasites give rise in man to a dangerous and often fatal fever, a marked character of which is the tendency to relapse. Hence it is known as recurrent or relapsing fever. The cause of relapsing fever has been long known to be a Spirochæte, viz. *S. obermeieri*, but it is only recently that the nature of "African tick fever" has been elucidated. This is also due to a Spirochæte, and as it is different from the former it has been named *S. duttoni* after the late Dr. Dutton, who with Todd was the first to elucidate the mode of transmission of the disease. The memoir of the Liverpool School of Tropical Medicine contains an elaborate study clinical and experimental of the characters of this Spirochæte. Perhaps the most convincing proof brought that these two Spirochætes are different lies in the fact that an animal that has recovered from an attack of the one is still susceptible to inoculation with the other, and *vice versâ*. How the ordinary relapsing fever is transmitted is still uncertain; it may be by bugs, though the numerous experiments recorded in this memoir to transmit *S. duttoni* in this way have all failed, but ticks are the transmitters of *S. duttoni*, and in Africa the particular tick implicated is *Ornithodoros moubata* (Murray). This tick, long of evil reputation, can transmit the disease in the following ways:—(1) directly, i.e. by means of adults that have sucked the blood of infected patients, and (2) by the nymphal descendants of these adults. Spirochætes have also been found by Koch in the eggs of ticks, but whether or no they undergo any development is at present unknown.

From what we have said it will be evident that to the medical man a knowledge of ticks is of the utmost importance, and every medical man will welcome this memoir of Captain Christophers on the anatomy and histology of ticks. The histological portion will be especially useful, as the systematic treatises, e.g. Neumann's memoirs, deal solely with the external characters on which their classification is founded. The internal anatomy of ticks has until quite recently been described in a very meagre fashion, and it is evident that such a knowledge is absolutely necessary in the search for developmental forms of Piroplasma and Spirochæta in the various tissues.

Those who are acquainted with Captain Christophers's previous work on the anatomy and histology of the mosquito will know what to expect in this memoir.

The clear descriptions, illustrated by numerous diagrams and six photogravure plates, might with advantage be imitated by other recent writers on the same subject.

With regard to the plates, unfortunately in passing through the press the lettering of many of the figures has not appeared. We may note also that the secretion from the coxal glands was observed by Dutton and Todd in the Congo.

The Liverpool memoir, besides the study of *S. duttoni*, contains a description of various attempts made to cultivate this Spirochæte, but all in vain. A new Spirochæte in the mouse, *S. laverani*, is also described. Two papers on Trypanosomes, and a number of pictures of the research laboratories at Runcorn of the Liverpool Tropical School, complete a very interesting memoir.

J. W. W. STEPHENS.

TROPICAL BOTANY.

AN interesting number of the Annals of the Royal Botanic Gardens, Peradeniya (London: Dulau and Co.), has just appeared. In the first paper Mr. R. H. Lock gives the third instalment of his work on plant-breeding in the tropics, dealing with maize. Unlike some Mendelian experiments, the results have been obtained with large numbers, and on a total, for instance, of 111 697 seeds, the result was 50.17 against an expectation of 50.11.

The second paper is by Mr. T. Petch on the fungi of the nests of the common termites, or white ants, of Ceylon, a worthy successor of Moller's classical paper on the fungi of the leaf-cutting ants of South America. He has worked out in detail the entire life-histories of the fungi, and shows that while the "regular" fungus is a Volvaria (already described elsewhere, as are so many of the tropical fungi that have only been worked at in Europe, under at least six genera), the garden also contains "weeds," one of which, at least, a Xylaria, is impossible of eradication by the ants. Incidentally, grave doubt is thrown on Moller's theory of selection of the fungus by the ants, for the "Kohl-rabi heads" occur in the termite nests in an even more perfect and complex form than in the leaf cutters' nests, and yet the same form appears on an allied outside fungus not cultivated by the ants. The paper is well illustrated.

The third paper is by Dr. Willis, on the flora of Ritigala. This is an isolated mountain in the "dry" zone of Ceylon, forty miles from any other, and high enough to condense much moisture on the top, where are found 103 species not otherwise known in the dry zone. These, being species of the lower zone of the southern mountains, must have leapt the whole forty miles in one operation. Among them are twenty-four bird-carried things, with one very slightly marked endemic variety among them; forty-nine wind-carried things (including twenty-four ferns), with two endemic species and one variety; and thirty plants the mode of distribution of which may be called doubtful or accidental. Six of these are low-country plants which might come by easy stages, and of the remaining twenty-four no less than nine are endemic to Ceylon and to the couple of acres of the summit of Ritigala. One of these nine has been found in South India, but the other eight are confined to Ritigala. This goes to show, therefore, that endemism goes with difficulty of distribution and rare arrival in one spot.

The final paper is by Mr. A. M. Smith, who has followed up Blackman's already almost classical paper on optima and limiting factors by a careful study of growth under different conditions in Ceylon—where it is rapid, and can be easily measured—and finds that Blackman's theory explains matters well. In Dendrocalamus (giant bamboo) at Peradeniya the limiting factor is humidity, while at night at Hakgala, where it is cold, the temperature is limiting and humidity has no effect. This work explains, but renders practically valueless, the enormous mass of observations on growth made by physiologists from Sachs onwards, and no one interested in physiology can afford to leave this paper unread. It also helps to show what an opening there is for really good physiological work in the tropics. The whole number is one of considerable interest and importance, and cannot be neglected by botanists.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

MR J E S MOORE has been elected to the chair of experimental and pathological cytology, recently established in the University of Liverpool by the Liverpool Cancer Research Committee

A SERVICE for members of the University of London will be held in Westminster Abbey on Wednesday, May 8, presentation day, at 6 p m The Dean of Westminster has consented to preach the sermon

PROF M D'OCAGNE, of the École des Ponts et Chaussées, will deliver in April, at the University of Paris, a free course of lectures on graphic calculus and nomography In the second part he will give for the first time in a public lecture a complete account of his own methods on the subject

MR BIRRELL announced in the House of Commons on March 23 that the Treasury has agreed to place at the disposal of Ireland a sum of 40,000*l* a year for a period of three years to assist to remedy the present disgraceful condition of Irish school buildings There is no intention of stopping the grant at the end of three years, but it is felt, Mr Birrell said, that 40,000*l* is as much as can be spent profitably and usefully in a year

WE have received an interesting description of the central electric power station of the Victoria Jubilee Technical Institute Byculla, Bombay, which was opened by the Governor of Bombay on February 20 The installation, the first of its kind in India, is thoroughly up to date, and it is interesting to note that the erection of the boiler, engines, dynamo and motors, as well as all piping and wiring work, was carried out by the institute students

IN the *Engineering Magazine* (vol xxxii, No 6) Commander W I Worthington discusses the United States Naval Academy as an engineering school With the aid of numerous excellent photographs he shows the number, variety, and interesting character of the practical exercises and expresses the opinion that the academy graduate at the end of a term of years after graduation should rank high among engineers of his own age from other schools no matter what branch of the work he might take up

A CIRCULATING library from which the most recent scientific and technical books may be obtained without trouble and at a moderate expense is a great convenience alike to teachers and students of science Mr H K Lewis of Gower Street, London W C, has realised this fact and his recently published list of medical and scientific books issued during the last quarter of 1906 shows that he makes every effort to keep his library up to date, and that the conditions under which books may be borrowed have been made as simple as possible

IN connection with the Federal Educational Conference which the League of the Empire has arranged for May 24 the nature-study section intends to make (for the benefit of the colonial representatives) an exhibit typical of nature study work in this country The section will also meet during the week devoted to the conference in order to discuss matters connected with the promotion of nature-study Suggestions as to topics that might be considered should be sent to Mr Wilfred Mark Webb (honorary secretary of the nature-study section) at Caxton Hall, Westminster

THE organising committee of the International Congress for Hygiene and Demography which is to be held in Berlin on September 23–29 is making arrangements to render it possible for members of the congress to visit the numerous hygienic institutions in and near Berlin The meetings of sections will not be extended later than 2 o'clock, so as to leave the afternoons free for visiting More than a hundred institutions will be thrown open to visitors, and a "Hygienic Guide" giving a short description of each of them in three languages is to be published, so that members of the congress will be assisted in choosing which institutions they will inspect A local committee composed of representatives of interested Imperial and State offices the Berlin Council, and other bodies and societies, is actively engaged in preparing for the congress

THE President of the Board of Agriculture and Fisheries has appointed a departmental committee to inquire as to the provision which has now been made for affording scientific and technical instruction in agriculture in England and Wales and to report whether, in view of the practical results which have already been obtained, the existing facilities for the purpose are satisfactory and sufficient, and, if not, in what manner they may with advantage be modified or extended The committee will be constituted as follows, viz —Lord Reay (chairman) the Lord Barnard Lord Moreton, Mr F D Acland, M P, Mr D Davies, M P Mr N Lamont M P Mr T Latham Mr J C Medd Prof T H Middleton, Prof W Somerville and Mr H Staveley-Hill, M P Mr A E Brooke-Hunt, of the Board of Agriculture and Fisheries will act as secretary and Mr H L French, of the Board of Agriculture and Fisheries as assistant secretary to the committee

THE general committee responsible for the arrangements in connection with the second International Congress on School Hygiene, to be held under the presidency of Sir Lauder Brunton in London next August is sparing no pains to make the congress a complete success A meeting to promote the interests of the congress was held on March 20 at the Mansion House, and was well attended Sir Lauder Brunton explained the objects in view and gave a detailed description of the groups of subjects to be considered by the congress There will be eleven sections as follows the physiology and psychology of educational methods and work medical and hygienic inspection in school, the hygiene of the teaching profession instruction in hygiene for teachers and scholars physical education and training in personal hygiene out-of-school hygiene and the relations of home and school, contagious diseases, ill-health, and other conditions affecting attendance special schools for the feeble minded special schools for blind deaf, dumb, crippled, and invalid hygiene of residential schools the school building and its equipment Already the donations promised and received reach 927*l* Further subscriptions are solicited and should be sent to the treasurer Sir Richard B Martin, Bart, at the Congress Office, Royal Sanitary Institute, Margaret Street London, W

MR MCKENNA M P, President of the Board of Education was present at the annual dinner of old students of the Royal School of Mines on Tuesday, and in the course of a speech he made the announcement that the school is to retain its name and individuality in the Royal Technical Institute to be established at South Kensington Mr D A Louis presided at the dinner, and in proposing the toast of the evening "Prosperity to the School of Mines" he said it is of vital importance that there should be a well-equipped national institution for the training of mining engineers, and that the institution should grant a distinctive diploma The Royal School of Mines is such an institution yet it has been proposed to relegate it to some hole-and-corner place in a big jumble of institutions which have nothing in common with it excellent though they are in their own way Mr McKenna in the course of his remarks, said that the school needs more and better equipment in order to provide it with the means of coping with rival institutions in various parts of the world He hopes that in future the failure to make this provision will be remedied In a memorial from past students of the Royal School of Mines to a departmental committee which inquired into the formation of the new technological college three requests were made, namely – "(1) that the title be retained as 'The Royal School of Mines' (2) that the diploma of 'Associate of the Royal School of Mines be retained as heretofore (3) that the school even though it may be affiliated to some central institution be preserved as a separate entity as regards mining and metallurgical training with its own special staff and organisation" As an answer to these requests, Mr McKenna read a paragraph from a draft of a charter which may be issued hereafter The clause states that "One of the

departments of instruction of the new institution shall provide specialised courses in mining and metallurgy, and that department shall be called and known by the name of 'The Royal School of Mines,' and the governing body shall award the diploma of 'Associate of the Royal School of Mines' to any student who completes such courses to the satisfaction of the governing body." The individuality and history of the school will thus be preserved, and will not be sacrificed in what the chairman called a jumble. In conclusion, Mr McKenna expressed the hope that though in joining a larger association the school necessarily will sacrifice a certain amount of individuality as a governing body, nevertheless by retaining the name and the diploma it will be compensated for any respect in which it may suffer by the advantages which will accrue from the fuller and more complete equipment. The name and the fame of the Royal School of Mines must be kept bright as a star in the firmament of the new institution which is to be a pioneer even to Germany in the work of scientific training.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 13, 1906.—"An Examination of the Lighter Constituents of Air." By J. E. **Coates**. Communicated by Sir William Ramsay, F.R.S.

About 73,000 litres of air were systematically fractionated in order to ascertain whether any constituent lighter than hydrogen (e.g. coronium) were present. A preliminary concentration of the lighter portions was effected by collecting the gas which had passed repeatedly through an air-liquefying plant, precautions being taken to avoid contamination of the gas with hydrogen. By fractionation of the liquefied gas, a light portion having a volume of about 4700 c.c. was obtained, which was further fractionated by absorption in charcoal at about $-205°$ C. The lightest fractions thus obtained were examined spectroscopically, but no lines were detected which could not be attributed to hydrogen, helium, and neon. The volume of hydrogen amounted to 0.778 c.c., while the total volume of neon and helium obtained was 46 c.c. Assuming that 60,000 volumes of air contain one volume of mixed neon and helium, it appears that hydrogen is present in the air to the extent of one part in about a million and a half. This estimate has been subjected to a correction for the solubility of hydrogen in liquid air, an approximate correcting factor being obtained by performing the fractionations on a sample of air to which a known small quantity of hydrogen had been added. This is much smaller than previous estimates; it seems probable that hydrogen is a variable constituent of the atmosphere.

January 31.—"A Recording Calorimeter for Explosions." By Prof. Bertram **Hopkinson**. Communicated by Prof. H. L. Callendar, F.R.S.

This paper describes a method of recording the heat lost up to any instant after an explosion of coal-gas and air in a closed vessel. For this purpose the vessel, which was cylindrical and about 1 foot in diameter and 1 foot long, was lined first with a wooden backing $\frac{1}{2}$-inch thick and then with a continuous length of copper strip $\frac{1}{2}$-inch wide by 1/25 inch thick. The strip was wound helically on the cylindrical part of the vessel, and the two end-plates were covered with parallel pieces joined up at the ends so as to form an electrically continuous length.

The method consists in recording the rise of resistance of the whole length of copper strip when the explosion takes place. The rise of resistance is proportional to the rise of mean temperature of the strip. Hence, knowing the heat capacity of the copper, the total heat that has passed into it at any instant can be obtained from the record after making certain corrections for the heat which has passed from the copper into the backing and into those parts of the walls which are not protected by the copper.

The record of resistance was obtained by passing a known current (about 8 amperes) through the strip and recording the potential at the terminals of the strip by means of a reflecting galvanometer having a period of about 1/15th of a second. The galvanometer was placed in series with a constant source of E.M.F. of such magnitude as to balance the E.M.F. at the terminals of the strip when cold; the galvanometer deflection was then proportional to the rise of E.M.F. between the terminals of the strip, and so to the rise of resistance. The galvanometer mirror reflected an image of a fine hole illuminated by an arc lamp on to a photographic film carried on a revolving drum. A photographic record of the pressure in the vessel was obtained at the same time on the same film.

The mixture used consisted of one part of coal-gas and about seven parts of air at atmospheric pressure and temperature. It was fired by an electric spark at the centre of the vessel. To test the accuracy of the calorimeter, the heat which had passed into the walls at the end of one second from firing was calculated from the record, and was found to be 10,000 calories. The temperature of the gas at that moment was found from the pressure record to be 545° C. Using Holborn and Austin's values for the specific heats of the constituents up to that temperature, the heat remaining in the gas was calculated to be 3800 calories. The total heat accounted for by the calorimeter and pressure records is therefore 13,800 calories, and this should be equal to the heat of combustion of the coal-gas used. This was the case within 2 per cent.

The calorimeter record shows that during about two-fifths of a second after firing the rate of heat loss to the walls at any moment is approximately inversely proportional to the square root of the time. That is, the law of heat loss is initially the same as that of a solid at uniform temperature the boundary of which is suddenly cooled. It is pointed out that the rate of cooling is conditioned mainly by the state of the surface layer of gas in contact with the walls; at first heat is drawn from that layer, and the loss of heat is very rapid, but when the surface layer has been cooled down it acts as heat insulation for the remainder, and further cooling is relatively slow.

Linnean Society, February 21.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The Percy Sladen Trust Expedition to the Indian Ocean in 1905 under Mr. J. Stanley Gardiner: (1) Description of the expedition: (i.) Introduction, (ii.) history and equipment of the expedition, (iii.) *résumé* of the voyage and work. Part i., Colombo to Mauritius: J. Stanley **Gardiner** and C. Foster **Cooper**.—(2) Land nemerteans, with a note on the distribution of the group: R. C. **Punnett**. A single land nemertean obtained by Mr. Stanley Gardiner in the Seychelles must be referred to a new species, and has accordingly been named *Geonemertes arboricola*. The specific name has reference to the peculiar habitat of the worm, which occurs, among other places, in the leaf-bases of the screw-pine, *Pandanus hornei*.—(3) I and Crustacea: L. A. **Borradaile**. The collection contained thirty species, belonging to eleven genera. None were new to science, and all had previously been reported from the Indian Ocean. The fauna revealed by the collection is richer than that of the Maldives and Laccadives, but otherwise closely resembles it.—(4) Hymenoptera: P. **Cameron**. Thirty-two species of the group were obtained, ants being excepted. Of these seventeen are described as new, one *Tolbia scaevola* as the type of a new genus. Ten species were obtained from the Chagos, three being new, and twenty-three from the Seychelles, including Coetivy, eleven new, the fauna for this archipelago now consisting of twenty-four species. As regards the habits of the species, it is suggestive that so many of them belong to genera (Evania, Ampulex, Sphex, Notogonia, &c.) of which many, if not most, of the species prey on Orthoptera.—(5) Dragon-flies: F. F. **Laidlaw**. The collection contains fourteen species, none of which are new. All were obtained in the Seychelles, and four in the Chagos as well. It is suggested that the species peculiar to the Seychelles are a fragment of an endemic fauna, which is being displaced throughout the whole Indo-African region by an invading fauna from the north.—(6) Fourmis des Seychelles, Amirantes, Farquhar et Chagos, déterminées par H. A. **Forel**. Nous avons pour les divers groupes d'îles en question 8 espèces cosmopolites, 8 espèces malgaches,

8 formes locales, qui ont toutes dans leur dérivation un caractère malgache, trois formes locales (sous-espèces ou variétés) dérivées d'espèces indomalaises, une espèce océanienne, une espèce américaine évidemment importée et ayant un peu varié, puis deux formes communes aux archipels mais l'une au moins décidément dérivée malgache Enfin, une espèce (*Pheidole punctulata*) et une sous-espèce (*Camponotus grandidieri*) tout communes aux faunes africaine et malgache, probablement dérivées de la première —(7) Pycnogonida Prof G H **Carpenter.** Only five species of the group were obtained, of which four are described as new The most remarkable is a Colossendeis from 450 fathoms off the Saya de Malha Bank —(8) Aves Dr H F **Gadow,** F R S, and J Stanley **Gardiner** The birds obtained were in no way remarkable, being mostly waders or regular sea-birds of wide distribution The crab-plover (*Dromas ardeola*) was found everywhere Of economic importance as guano-formers were breeding colonies of *Fregata ariel* on Nelson Island, Chagos, *Sula piscator* on St Pierre, *Sterna fuliginosa* and *Anous leucocapillus* on Cargados Carajos, and *Pelecanus crispus* and *Puffinus tenuirostris* on St Joseph, Amirante Islands

Society of Chemical Industry, March 4 —Mr R J Friswell in the chair —Five years' experience in measuring and testing producer gas R **Threlfall,** F R S The first part of the paper is devoted to a *résumé* of the principles and construction of the instruments employed in Pitot tube gas measurement This is followed by a description of the "static" method of measuring gas density An account is then given of the results of balancing the make and distribution of producer gas over a period of several years this being illustrated by curves which show that an agreement within about 2 per cent can be attained in practice The next section of the paper is devoted to a discussion of the theory and practice of measuring pulsating streams of gas or air, such, for instance, as are produced by pumping by gas-engines or otherwise As to the question of sulphur in producer gas, it is shown that the referee's test is less suitable for this purpose than a modification of Valentine's test The discussion of this matter covers both the determination of sulphuretted hydrogen and of total sulphur, and it is shown that it is fatal to the sulphuretted hydrogen to employ a gas meter containing water—no matter how long it may have been in action The best methods hitherto proposed and practised for the determination of the volume of gas produced per ton of coal, otherwise than by the author's meters, are considered critically and some examples are given of the results of balancing on carbon and on ammonia The paper ends with a note on the determination of producer temperatures by a system of thermocouples which are read by a potentiometer suitably divided to read direct, and fed by a very large Clark or cadmium cell

Zoological Society, March 5 —Mr. F Gillett, vice president, in the chair —The discovery, in cave deposits in Crete, of remains of elephants, some of which represent a new species Miss D M A **Bate** —Report on the Polyzoa of the third Tanganyika expedition C F **Rousselet.** Five species were represented in the collection, three of which were described as new Of the five species, three belonged to the Phylactolæmata and two to the Gymnolæmata Amongst the latter was *Arachnoidia raylankesteri*, Moore, which was found in some abundance on shells dredged from deep water — Report on the Brachyurous Crustacea of the third Tanganyika expedition Dr W A **Cunnington.** The collection contained specimens from both Nyasa and Tanganyika Including a few individuals which had hitherto passed without notice in the collection of the British Museum, there were now on record three species from Nyasa and five from Tanganyika Of these species, three were described as new The forms from Nyasa all belonged to the widely distributed subgenus Potamonautes, but while two species from Tanganyika also belonged to that subgenus, the lake contained three species belonging to the remarkable endemic genus Platythelphusa, A Milne-Edwards The suggested marine appearance of *P armata* was considered to be only superficial, and the peculiar character of the Brachyuran fauna of Tanganyika could be explained on the grounds of a prolonged isolation of the lake —Two new species of African oligochæte worms of the genus Microchætus belonging to the collection of the Christiania Museum F E **Beddard.**

Physical Society, March 8 —Prof J Perry, F R S, president, in the chair —The rate of recovery of residual charge in electric condensers Prof F T **Trouton** and S **Russ.** The experiments described by the authors were undertaken in order to examine the rate of recovery of residual charge when the difference in potential of the plates is kept constant Previous experimenters have always allowed the charge to accumulate on the plates while observing the rate of rise in potential In that case the recovery meets with an ever-increasing opposition which complicates matters The authors have employed two methods In the first, which was used with mica condensers, the potential, observed by an electrometer, was kept constant by means of a variable resistance which was gradually increased as the recovery current diminished The high resistance necessary was constructed of two horizontal metal plates with ionised air between them A movable shutter could be introduced between the plates to diminish gradually the cross-section of the air resistance as required The second method was used when the residual charge was great enough In it the current was passed through a dead beat galvanometer, and the value of the recovery current at each moment determined In this case the difference of potential of the plates may be taken as constant since it was practically zero The observations when plotted with current against time were found to lie on a hyperbola This shows that in the circumstances of the experiments the quantity of electricity recovered up to any given time follows a law $Q = a \log(p+t)$ similar to that found by Rankine and others for the recovery of stress in overstrained elastic bodies when the strain is kept constant

MANCHESTER

Literary and Philosophical Society, February 12 —Mr Francis Nicholson in the chair —Some tables for explaining the nature of statistical correlation A D **Darbishire** The thirteen tables exhibited graphically the results of thirteen series of pairs of throws of dice in such a way that the effect of increasing the correlation between the first and second throws of the pair was clearly seen The method is an application, to some new sets of throws, of Weldon's beautiful device for illustrating statistical correlation

February 26 —Prof H B Dixon F R S in the chair —Report on the recent Foraminifera from the coast of the Island of Delos (Grecian Archipelago), part iv H **Sidebottom** Drawings of some of the more interesting species were exhibited and mounted specimens were shown under the microscope —The leaves of Passerina Madeline **Carson** The Passerinæ belong to the natural order Thymelæaceæ These plants inhabit the warm dry regions of Egypt, South Africa and the Mediterranean They are common on the sand hills near the coast, and always live under conditions in which there is a difficulty of obtaining water In order to combat against this, they are specially modified The leaf surface is reduced, often the leaves are imbricating They are provided with a very thick cuticle have the edges inrolled, and the stomates are found only on the inner surface They are further protected by a covering of hairs The chief object of the study of these leaves was to discover whether the epidermal cells contained mucilage or not In *Passerina filiformis* and in *P hirsuta* the author found that in many of the epidermal cells a portion was cut off from the rest by a cellulose wall The upper portion contained tannin and probably mucilaginous sap while the lower portion consisted of hard stratified mucilage In the other species examined *Passerina ericoides* and *P rigida* no trace was found of separation of the epidermal cells into a striated and non-striated portion The whole epidermal cell stained with mucilage stains and tannin stains Since mucilage and tannin both act in the same way towards methylene blue and since it is impossible to separate tannin and mucilage the evidence for the presence of mucilage in these species is not perfectly conclusive As however mucilage is with

out doubt found in some Passerinæ, its absence is not characteristic of the group and therefore its presence or absence can no longer be used as a basis for classification of the Thymelæaceæ

PARIS

CHEMICAL CRYSTALLOGRAPHY

Chemische Krystallographie. By P. Groth. Erster Teil. Pp. viii+626. (Leipzig: W. Engelmann, 1906.) Price 20 marks.

THE appearance of the first volume of this monumental work by Prof. P. von Groth marks an epoch in the history of crystallography. Ever since it was known that the famous editor of the *Zeitschrift für Krystallographie* had such a work in progress, expectancy has been of the keenest in the mineralogical and crystallographical world. That the book would be worthy of the man was felt to be assured, and the event has fully justified such confidence. It is to be published in four volumes, and if the other three are equal to the first now before us, the whole will form a compendium of crystallographic knowledge which for completeness, detail, and accuracy will stand unique. The work will include practically the whole of our crystallographic knowledge concerning every crystallised substance yet described.

There can be no doubt that Prof. von Groth is particularly marked out by circumstances for the compilation of such a *magnum opus*. For not only has he edited the *Zeitschrift für Krystallographie* since its inception by him thirty years ago, but he has exhibited from time to time, especially by the rapid succession of new editions of his standard text-book, "Physikalische Krystallographie," and his smaller but not less interesting "Einleitung in der chemische Krystallographie," a remarkable gift of assimilating, weighing, collating, and presenting in readable and indeed highly interesting form the chief advances in crystallography as they occur. His most careful personal editorship of every paper of importance which is published in the *Zeitschrift* has rendered him familiar with these advances in all their details. Moreover, his reputation as a teacher has made his laboratory at Munich the resort of as earnest and enthusiastic a class of students as is to be found anywhere. Hence this book will be received by all those interested in crystallography with a quite unusually warm welcome, deeply tinged with reverence, partly on account of the excellence of the material which the book itself contains, but in even greater measure because of the respect with which every word uttered by the great master and universally acknowledged *doyen* of his subject is received.

In Britain the book will meet with an exceptionally cordial reception from the small band of our native crystallographers, who have ever been treated by Prof. von Groth with particular kindliness, and have received from him the strongest encouragement, and never more so than at times when it has unfortunately been only too evident that the study of crystals was not appreciated in this country. The writer of this review can never forget the more than kind encouragement extended to him by Prof. von Groth during the earlier stages of the organised series of researches which the writer inaugurated in the year 1891 on the alkali sulphates and selenates and their double salts, and which had for their first object the introduction of greater accuracy into crystallographic methods. Prof. von Groth has frequently expressed the wish that the country of Miller, the father of modern crystallography, should take a much greater part in the advance of crystallography than she was doing some fifteen years ago. Now, however, at last the small band of British workers, partly from the stimulating influence of such encouragement, has been able to make some impression, and not only mineralogists, who have alone in the past appreciated crystallography at its true value, but chemists, to whom its intrinsic value is immeasurable, as well as metallurgists and physicists, are awakening to the fact that the study of crystals is the study of solid matter in its highest, most perfectly organised form, and that it is likely to lead to the most important fundamental truths. Already the researches just alluded to have afforded a final and irrefragable proof of the accuracy of Haüy's original conception that to every definite chemical substance there appertains a distinct and characteristic crystalline form, and have reconciled this with Mitscherlich's discoveries in isomorphism by revealing an exquisitely beautiful relationship, connecting very small angular differences which are found to occur between the crystals of the various members of isomorphous series with the atomic weight of the interchangeable elements composing them. This generalisation not only defines the real meaning, extent, and scope of Mitscherlich's law, but also proves that the supposed exceptions are not such, and therefore the absolute truth of the rule that difference of chemical composition does in all cases involve difference of crystalline form.

That the subject to the advance of which Prof. von Groth has devoted himself is indeed of the intrinsic importance which the writer has recently claimed for it, in a couple of articles in the engineering supplement of the *Times*, is strikingly demonstrated by the fact that the very groundwork of chemistry, the law of valency, has been shown in a remarkable paper by Prof. Pope and Mr. Barlow, read recently to a crowded audience at the Chemical Society, to be clearly connected with, if not dependent upon, the internal structure of crystals. This most interesting theory carries the conception of "topic axes," which express the relative structural dimensions of the crystals of isomorphous series, and which were introduced simultaneously by Dr. (now Prof.) Muthmann, one of Prof. von Groth's pupils and assistants, and the writer in the year 1894, a step further so as to include no longer merely the members of isomorphous series, but also substances of the most diverse characters, and whatever may be the fate of this theory it can no longer be doubted that crystallography must play a much more important *rôle* among the subjects of science in the future than it has played in the past.

The present juncture, therefore, is a most opportune one for the appearance of Prof. von Groth's great book. It will be invaluable to all crystallographical investigators, and particularly so as an excellent bibliography of all the important investigations up to date

is included concerning every substance discussed. This first volume deals with the solid elements, with the inorganic compounds of a non-saline character, such as oxides, sulphides, and phosphides, and with the halogen salts, cyanides, and salts of the recently discovered nitrogen acids. The second volume is to deal with the inorganic oxy- and sulpho-salts and the remaining inorganic crystalline compounds, while the third and fourth volumes are to treat of the organic compounds. The arrangement of the text is that each group is described as regards its general characteristics in an introductory statement in large type, and this is then followed by the detailed description of each member of the group in smaller type.

An excellent *résumé* of the crystallography of the naturally occurring minerals is given, but it is the detailed crystallography of the substances requiring to be prepared chemically, and the descriptions of which cannot be found elsewhere except by reference to the widely scattered original memoirs, that renders the book so priceless, for it presents the essential results of all chemico-crystallographical investigations right up to date. The illustrative figures of crystals are neat and clear, and the text easy, the large type even luxurious, to read.

One important feature has been left to the last to refer to, namely, that the symmetry of the crystals of each substance dealt with is given in accordance with the much more scientific method of classification recently adopted as the outcome of the completion by Schönflies, Fedorow, and Barlow of the geometrical theory of homogeneous structures, which enables the particular individual class represented in the substance under discussion to be at once identified from among the thirty-two possible classes of crystal symmetry.

In conclusion, with regard to the contents of this book, the best of all possible praise can conscientiously be bestowed in saying that it is worthy of the master-mind that conceived it.

A. E. H. Tutton.

A NEW WORK ON ORGANIC EVOLUTION.

The Analysis of Racial Descent in Animals. By T. H. Montgomery, jun. Pp. xi+311. (New York: Henry Holt and Company; London: George Bell and Sons, 1906.) Price 10s. 6d. net.

IT would be a most fascinating task to trace the evolution of modern methods of dealing with the problems of life. Differentiation has taken place so extraordinarily quickly. The time is long past when one man can attempt to grapple with the whole problem. Not only so, but the time seems to be past when one man can even be interested in the whole problem. Evolutionists may be broadly classified into those to whom the problem of evolution is the problem of the origin of species and those to whom it is the problem of adaptation. The key-note of de Vries's "Mutationstheorie" is the solution of the problem of species; we even go so far as to say that this is the achievement of de Vries's work. The logical conclusion, the complete working out of the theory of natural selection, is reached in Dr. Archdall Reid's "Principles of Heredity." The interest of the two authors is entirely different. De Vries's interest is in the origin of species, Dr. Reid's in natural selection. Darwin's interest was in both; if we look no further than the title of his chief work we can see this—"On the Origin of Species by Means of Natural Selection."

The fact that these two interests have segregated, and the way in which they have segregated are both very suggestive, and the direction in which they point is the same. The fact of segregation suggests that the association of the two ideas was unnatural, and that they were not capable of union. The way in which they have segregated confirms this suspicion. For those who devote their attention to the question of species reject natural selection, while those who elaborate the theory of natural selection find no support in the phenomenon of specific difference. All possibility of a reconcilement between the divorced ideas is put an end to by Meyrick, who probably knows more about specific difference than anyone else. In his handbook of British Lepidoptera he says that, in seeking for the most suitable characters by which species may be distinguished, those which can in any way be regarded as useful to the species must be discarded without more ado.

It is not surprising that Darwin's work should have borne fruit which segregated in this way. The case is thoroughly Mendelian. Darwin's work was a cross between a biological theory of evolution and a social and industrial theory of competition. The hybrid, more vigorous than either parent, took the world by storm. We are now witnessing its posterity separating out more or less simply into the two forms which were united in the beginning. Just as every plant in the F_1 generation contains yellow and green peas, and just as it is not until the next that there can be found plants bearing only yellows or only greens, so Darwin's interest was in the "Origin of Species by Natural Selection," while now we find de Vries, who is absorbed entirely with the former, and Reid entirely with the latter.

The immediate result of Darwin's work was the flood of energy which spent itself in tracing out the genealogical histories of organisms. To such lengths did the students of phylogeny go, so remote from reality did their speculations become, that the study of phylogeny has fallen into discredit in the eyes of a great many of those who are looked up to as biological thinkers to-day.

Prof. Montgomery's interest is centred neither in species nor in selection, but in phylogeny. He admits that phylogeny has been discredited by the indiscretion and shallowness of a number of its exponents, but he contends that if we limit ourselves to the strictly experimental method we are neglecting an enormous range of phenomena.

"For living organisms are in number and variety hardly commensurate with the vast assemblage of their ancestors. Are we then to leave out of consideration all this once existing life, simply because

its units are no longer subject to experiment? Most assuredly not"

Our author undertakes the herculean task, we venture to think successfully, of setting the study of phylogeny on a surer foundation The reason that phylogenetic inquiry has become discredited is that the majority of biologists are neither so stupid that they are content to dabble with phylogeny nor clever enough to make it a great and fruitful sphere of inquiry—a field fit for the exercise of the highest intelligence

The experimental method has its limitations no less than its fascination It is not merely a paradox to say that in biology those things with which we can experiment most are those which to the organism matter least The reason is that we are not the first to start experimenting Nature has been there before For example, the range of continuous variation in an organism may either be the direct result of the constitution of the living substance or it may have been determined by the most stringent selection acting since life dawned If, therefore we institute experiments on variation—for example the determination of the effect of heat on the range of variation—we may either be studying one of the simple properties of protoplasm or discovering the limits within which natural selection allows the particular organism dealt with to vary under the conditions of heat, *e g*, to which we subject it The really fundamental processes do not lend themselves to experiment That is how they have become fundamental Everyone who wishes to train himself to study them should read Prof Montgomery's book

There are a few trifling misprints, *e g* "embryoning" in the table of contents, and Mendel worked not with the sweet, but with the culinary pea

ELECTRIC RAILWAYS

Electric Railway Engineering By H F Parshall and H M Hobart Pp xxiv+475 (London Archibald Constable and Co Ltd 1907) Price 42s net

THE authors of this work have already introduced a series of technical works upon dynamo design and kindred subjects and Mr Hobart is also known as the author of a recent work upon the steam turbine

In the present volume the authors deal with a wider range of subjects, and, in short, treat of the whole question of heavy "electric traction," that is traction as applied to railways rather than to street tramways Such a book was required, and will be welcomed by the growing class of engineers who wish to add to their experience of steam railway work some knowledge of electrical engineering, which is more and more coming to invade the field of traction

Technical works of this kind may, as a rule, be divided into two classes, on the one hand are the highly technical works which deal with the more scientific aspects of the subject, and of which the authors' "Dynamo Design" is an example, on the other are the entirely practical works which, at their worst, degenerate into collections of specifications The present volume endeavours, not unsuccessfully to combine these two, and to give the reader a clear knowledge of the fundamental principles that underlie the application of electricity to haulage, illustrations of the methods employed in carrying this into effect, and actual examples and details of construction What it does not fully supply, and what unfortunately, books of this kind very seldom contain, are the commercial results obtained from the adoption of electric traction It may be said that this is outside the scope of an engineering treatise, and if the work is to comprise engineering in the sense in which that word was commonly used during the last century the answer is justified, for the engineer of those days was concerned with the question of "will it work?" rather than the question of "will it pay?" But the engineer of the twentieth century has become more and more obliged to look upon the latter as the test of successful engineering, and until a book can be produced dealing with electric traction from the operating point of view such works will not, it is to be feared, have much effect in influencing railway authorities to replace steam haulage by electric traction Apart from these limitations however, the present volume is most valuable for although a considerable portion of the matter has been already published in one form or another, there was a great need for bringing together all that has been done and written

The choice of the system to be adopted upon any particular part of a railway, although necessarily influenced by first cost, should ultimately be dependent upon its suitability for use upon the railway as a whole, and the results obtained from electrification must be judged in reference to the whole railway undertaking rather than in connection with one section In connection with the vexed question of the relative advantages of direct current, single phase or three phase, the authors do not undertake to predict the form that the ultimate electric railway installation will assume, contenting themselves with pointing out the merits of each, and emphasising the fact that standardisation has been one of the great elements of success in steam railway working, and that the adoption of electric traction upon railways in the future will be slow until standardisation is adopted

Coming now to the contents of the book itself it consists of three parts, dealing respectively with the mechanics of electric traction, the generation and transmission of the electrical energy and the rolling stock Chapter i deals with "tractive resistance at constant speed," and gives the results of applying both theoretical and arbitrary formulæ to the result obtained in actual practice

Chapter ii deals in a similar manner with the problem of acceleration Many useful curves of acceleration, speed-time, and speed-distance are given Chapter iii deals with tractive force in relation to acceleration, while chapter iv deals with the

characteristics of railway motors, upon the design of which Mr. Hobart is an acknowledged authority. Throughout the whole of this section a liberal use is made of graphical methods, and a number of curves referring to the energy consumption under different conditions in actual practice is given.

Chapter v. deals with the generating plant, and is, in our opinion, so far as the practical value of the information contained is concerned, scarcely so useful as the rest of the book; considerable space is devoted to descriptions of tramway generating stations, which, however up to date at the time of construction, are hardly representative of the most modern practice. The question of power-station design is a subject of its own, and is not one upon which the railway engineer, pure and simple, is often called upon to express an opinion. A design is given, however, of a proposed 10,000-kilowatt station, but so far as can be judged from the drawing the "complete unit" system by which, for safety reasons, the plant and buildings are entirely subdivided does not appear to be recommended. Interesting tables of the comparative cost and annual over all efficiencies of various generating stations are given.

A chapter upon the transmission of the electrical energy calls for no particular comment; sections of the cables adopted on various railway systems and the sizes of such cables are given. Particulars are also given of the cost of these cables, but the value of this is, of course, greatly dependent upon the price of copper. Substations are next dealt with, details being given of a very large number of actual substations used in railway work.

Chapter viii., dealing with the distributing system, in other words the third rail, is of more interest, and contains a number of tables dealing with recent practice in this connection; overhead work is also illustrated, though not so fully as could be wished.

Part iii. deals with rolling-stock, and is replete with illustrations and working drawings of locomotives and carriages. This portion of the book, however, shows signs of haste in editing, and in future editions we would suggest that the efficiency curves of motors which it contains, and, in fact, the reference to motors generally, should be gathered together in one section, namely, chapter iv., where most of them are already to be found, instead of being again dealt with under locomotives; certain of the data of rolling stock given in chapter iv. would, in our opinion, be more easily found in the chapter which is specially devoted to that branch.

These are, however, minor criticisms. The work is one of great practical value to all railway engineers, and will be further enhanced if in future editions more actual illustrations of the total costs of operation of electrified steam railways can be furnished. The North-Eastern Railway, the Lancashire and Yorkshire, and the District Railways have all been in operation long enough to furnish data of the greatest commercial value.

The general "get up" of the work is excellent, as are the reproductions of the various drawings.

OUR BOOK SHELF.

L'Année technique, 1906. By A. Da Cunha. Pp. xii+237; illustrated. (Paris: Gauthier-Villars, 1906.) Price 3.50 francs.

Since 1901 the author has each year prepared in attractive form a concise summary of recent progress in engineering, and his series of volumes cannot fail to prove of inestimable value to the student of French industrial history. His annual summary is not a mere compilation of disconnected notes, but a collection of essays written with originality, technical knowledge, and literary skill.

The subjects dealt with in the record for 1906 comprise accidents in works, the heating and water-supply of houses, public works, and locomotion. A museum illustrating the prevention of accidents in works having recently been inaugurated at the Conservatoire National des Arts et Métiers, Paris, the author has seized the opportunity of dealing at some length with the subject of industrial hygiene, and describes the museums that have been established with the object of bringing to public notice the arrangements that have been found by experience adapted for the protection of workmen in various industries. Museums of this kind exist at Zurich, Amsterdam, Vienna, Munich, Berlin, and Paris. The problem of efficaciously heating dwelling-houses is one that has long been under consideration. The old French fireplace, in which, it has been said, the hottest place is at the roof, has been superseded by modern fireplaces, by fixed or movable stoves, and by heating with steam or hot water.

Many ingenious improvements are described by the author, who also gives some useful advice on this important topic. Other interesting subjects dealt with include the installation of the huge compressed-air caissons for the passage of the Paris Metropolitan Railway under the Seine, the recent developments in automobile transport, and locomotion on ice and snow. The numerous illustrations have been carefully chosen and well executed, and the volume is produced in an attractive style at a modest price. Mr. Alfred Picard contributes a preface, which, like the rest of the volume, may be studied with profit and pleasure not only by the engineer, but also by the general reader desirous of acquainting himself with the events of the day.

Diseases of Fruit and Fruit-bearing Plants. (Board of Agriculture and Fisheries.) Seven diagrams and text. (London: Printed for H.M. Stationery Office by Darling and Son.)

The Board of Agriculture and Fisheries has issued a series of seven small coloured diagrams illustrative of a number of common diseases met with in cultivated plants, especially those which are grown for the sake of their fruit. They are adapted for use in schools in the country districts. They illustrate the general appearance of the diseased fruits, without any botanical details. Indications are given as to the best methods of prevention. The use of Bordeaux mixture is frequently and judiciously recommended, but no instructions are given as to the way in which the mixture should be prepared. It is certain that, in spite of the publicity which has been given to this excellent fungicide, many cultivators do not yet know how to prepare it. The use of liver of sulphur is also recommended, but the caution is not added that it should not be allowed to come in contact with the paint on frame or greenhouse, so as to prevent the discoloration that would otherwise ensue.

No attempt is made to indicate the degree of injury inflicted by various fungi; thus the first of the series, the "strawberry leaf-spot," is of very little conse-

quence as compared with No 2, the strawberry mildew The now famous American gooseberry disease is illustrated To prevent its spread, the use of one ounce of potassium sulphide dissolved in three gallons of water is recommended With this solution the bushes should be sprayed just before the leaves expand, and the spraying should be repeated at intervals as necessary It is unfortunate, we think, that the destruction of affected bushes by fire is not also recommended A descriptive pamphlet, for which one penny is asked, is supplied with the diagrams

La Mécanique des Phénomenes fondée sur les Analogies By M M Petrovitch (Belgrade) "Scientia" Phys-Math Series, No 27 Pp 96 (Paris Gauthier Villars, 1906) Price 2 francs

DR J W MELLOR, in his 'Chemical Statics and Dynamics," p 19, gives the following as the four stages of a physical theory —hypothesis, differential equation, integration, observation While this sequence is well illustrated in the study of dynamical phenomena, these, after all, constitute but a small proportion of the large number of effects in which changes are brought about by the action of definite causes This book while not containing any very novel and striking features, puts matters in a somewhat fresh light by giving prominence to the more philosophical aspect of the equations of mathematical physics and allied branches of science Thus the motions determined by a constant force, a positive, and a negative force varying as the distance, are all characterised by different known forms of the integrals of the equations of motion If in any phenomenon the changes which occur can be represented by equations of the form of one of these integrals then conversely the relation between cause and effect may be of the same form as the corresponding law of force The mathematical portion of the book is comparatively simple and about the hardest problem considered is that of forced oscillations in a resisting medium The book appears suitable for placing in the hands of such science students as have not the time to pursue an extended course in mathematics as they would doubtless get many hints from its perusal It may be doubted whether much is gained by the inclusion of physiological problems, such as the action of bacteria in the present discussion or whether such problems can indeed be adequately treated without introducing statistical considerations But there are many cases where, even if the analogy be not exact, it is more easy to picture the progress of phenomena by associating them with dynamical or other analogues, and the book will be useful if it teaches students to think in this way

The Steam-table A Table of the Thermal and Physical Properties of Saturated Steam Vapor and of the Specific Heat of Water Compiled from various sources by Prof Sidney A Reeve Pp ii+42 (New York The Macmillan Company, (London Macmillan and Co, Ltd) Price 1s 6d net

THIS is a very elaborate table from 400 lb per sq inch and 445° F down to 0·18 lb per sq inch and 32° F Usually we know a pressure in round numbers or a temperature in round numbers and two separate tables are needed, Mr Reeve's table contains both, and there is an ingenious arrangement for making interpolation easy There are entries for every degree and also for every pound per sq inch The usual error of such tables, using Regnault's heats with a value of Joule's equivalent which does not agree with Regnault's unit of heat seems to be avoided by Mr Reeve and this steam-table seems to us likely to prove of very great value to steam engineers

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Ionisation by Spraying

IN a paper published in the *Philosophical Magazine* (February) I noted that positive and negative ions could be observed in large quantities by an Ebert apparatus if fine spray from water were produced profusely in its neighbourhood Whilst much work has been done in connection with electrification caused by the bubbling of air through water and the splashing of drops, the effects due to spray do not appear to have received much attention

A description of a simple method of studying the ionisation by spraying, with a preliminary note of some of the results obtained, may therefore be of some interest A strong current of air, filtered through cotton wool, is passed for a definite time usually half a minute, through a small glass sprayer as supplied by Beckmann for introducing salts into a flame for spectroscopic work but in the present case the air and spray pass together into the large lower chamber of an electroscope containing an insulated cylinder connected with a gold-leaf system in a small upper chamber The leaf remains steady when air alone is driven into the lower chamber, except for a slight natural leak which remains constant in spite of much spraying

When spray has been introduced into the electroscope for half a minute the fall of potential is observed for that time, and from minute to minute until the leaf steadies to the natural leak The effect terminates in two or three minutes in the case of water but in the case of acetic acid, chloroform ether and the alcohols the ionisation effects do not disappear for ten to fifteen minutes, so that there are large inert ions, both positive and negative, present, some with a velocity of the order 10^{-4} cm sec in a field of 1 volt/cm Similar results have been found by Aselmann for salt solution

In most cases the positive and negative ions are generated in nearly equal quantities, but with water the negative ions are about 1·5 times as numerous as the positive The same ratio holds for ether of which the negative ions are more quickly removed than the positive The most important point, however is that small quantities of liquids can be examined by the help of these small sprayers and definite results obtained for the substances, if care is taken to avoid impurities

The following is a preliminary statement of the results obtained

Substances	Negative	Positive
Mercury	0	0
Toluene	0·02	0·02
Sea-salt and water	0·01	0·015
Hydrochloric acid and water	0·04	0·04
Pentane	0·07	0·03
Phenetol	0·08	0·08
Benzine	0·14	0·08
Ammonia water	0·45	0·30
Tap water	0·65	0·50
Distilled water	1·7	1·0
Ether	3·7	2·5
Chloroform, pure	2·3	2·3
Chloroform impure	4·5	4·5
Acetic acid	3·2	3·2
Methyl iodide	3·0	3·0
Methyl alcohol	3·0	3·0
Ethyl alcohol	3·5	3·5
Amyl alcohol	4·5	4·5

The figures are taken to an arbitrary standard and are expressed in terms of the positive ionisation due to distilled water It may be better ultimately to select ethyl alcohol as a standard of comparison, because the ionisation due to water varies sharply when any impurity is introduced

It is remarkable that volatile substances like benzine pentane phenetol and toluene should give rise to little or no ionisation when sprayed, whilst ether chloroform alcohol and aldehyde should so profusely form both positive and negative ions

A S EVE

McGill University, March 22

On the Extinct Emeu of the Small Islands off the South Coast of Australia and probably Tasmania

SOME of my colleagues in Australia, as I gather from "Notes" in NATURE (vol. lxxv., pp. 228, 467) have lately been at work on the identification of the small emeu of the islands in Bass Strait and Tasmania now extinct. Prof. Baldwin Spencer, of Melbourne, having examined the bones of the emeu which once lived on King Island and found them smaller than those of *Dromaeus ater* of Kangaroo Island, has felt justified in proposing a name for that bird, and has called it *D. minor*. Colonel Legge, an old colonist, has also been working on the King Island emeu, and proposed for it a name which, however, he withdrew in a postscript to his paper in favour of Prof. Spencer's one already published. From memory, having seen a pair in his boyhood, Colonel Legge considers the Tasmanian emeu a distinct *small* species.

Now I believe that the question of the emeus of small size which about a century ago yet lived in Tasmania and on the small islands off the south coast of Australia can only be settled by a careful comparison of their bones, and then and then only shall we know whether one or more species lived on those islands. I do not know of the existence in museums of specimens, either mounted skins or skeletons, of well authenticated Tasmanian emeus, but we possess two authentic skeletons and two mounted specimens of *Dromaeus ater* (Peron), which in the first years of last century was abundant on Kangaroo Island; two of these four specimens are in Paris, one is in Florence, and one in Liverpool. Mine is a skeleton, and is one of the three brought alive to France by Peron in 1803 from l'Ile Decrès (Kangaroo Island) (NATURE, vol. lxii., p. 102; *Ibis*, 1901, p. 1); the Liverpool specimen is, I think, not located; it is undoubtedly *D. ater*, but might hail from King Island or even from Tasmania; it may be the lost "lesser emea" of the Bullock Museum, dispersed in 1819.

I may now add that last summer my friend Mr. Alexander Morton, director of the Tasmanian Museum at Hobart, sent me some bones of the small emeu which he had collected on King Island in Bass Strait, asking me to compare them with the corresponding bones of the skeleton of *D. ater* in this museum. I did so at once, aided by Prof. E. Regàlia, a high authority on ornithic osteology; the result of our careful comparison was that, barring some slight differences of purely individual value, the remains of the three specimens from King Island examined *were absolutely identical* with the corresponding bones of Peron's specimen from Kangaroo Island. I therefore wrote to Mr. Morton (from whom I have not heard since) that I had not the slightest doubt that *D. ater* (Peron) once lived on King Island, and unless new evidence should show the contrary, I am much inclined to favour the hypothesis that the same diminutive emeu once lived in Tasmania. HENRY H. GIGLIOLI.

Royal Zoological Museum, Florence, March 20.

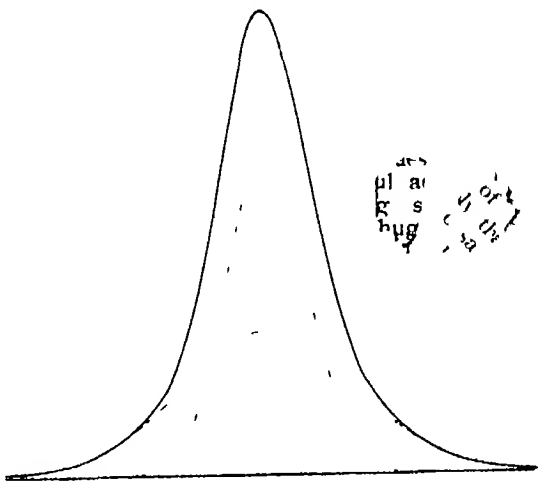
Mean or Median.

THE two applications of the *median* suggested in Mr. Galton's letter (NATURE, February 28) and his article (March 7) respectively, seem to me to be somewhat distinct.

In the case of a jury or committee voting as to a sum of money to be given there is no question of truth, but only of expediency. If any amount be proposed and put to the vote, the proposition will (by the ordinary way of voting) be defeated so long as that amount is above the median; the process of voting tends therefore to give an amount *not greater than* the median. Mr. Galton's suggested procedure is in this case, it seems to me, quite correct, and a saving of time would be effected if the problem were consciously approached from his standpoint.

The case of averaging a series of estimates with the view of arriving at objective truth appears to be on a different footing. If there is a considerable sprinkling of fools or knaves amongst the estimators, or of persons with a tendency to bias—as the buyers and sellers might be in judging the weight of cattle according to the suggestion of Mr. Hooker—the question as to choice of means is one that is difficult to answer. The important question is, in fact, not the "probable error," but the probable *bias*, for the whole frequency distribution may centre round an entirely erroneous value. If, on the other hand, the observers are honest and unbiassed, the choice of average turns on the form of the frequency distribution; we require that average which is (1) least erroneous, as a rule, (2) least subject to fluctuations of sampling—two conditions which may very well conflict. As regards (1), psychologists, following Fechner, suggest the geometric mean, I believe, as the best. But the distribution of guesses given by Mr. Galton does not appear to follow the law of the geometric mean; if it did, the median should be less, not greater, than the arithmetic mean. Further, so far as one can judge, the geometric mean would give a value as much too low as the median is too high. Looking at the distributions in Prof. Pearson's memoir on errors of judgment (Phil. Trans., 1902), there seems very little to choose between the mean, the median, and the mode; sometimes one is the best and sometimes another.

As regards (2), the probable error of the median has been discussed on several occasions by Prof. Edgeworth (*Phil. Mag.*, 1886, 1887; Camb. Phil. Trans., xiv., 1885). The value is $0.674 \ldots / 2h\sqrt{n}$, where h is the true ordinate of the frequency distribution at the median, i.e. $1/\sqrt{2\pi}\,\sigma$ for the normal curve. For the normal distribution, therefore, the probable error of the median is greater than that of the mean in the ratio of 1.25 : 1 approximately.



For a flatter topped curve with more curtate tails the ratio of probable errors is greater than 1.25 : 1, and accordingly for all such distributions the arithmetic mean is the better form of average. But for a curve with a high central peak and long tails the probable error of the median may be less than that of the mean, and it will be the more stable form of average. As an illustration Prof. Edgeworth has taken the case of a distribution compounded of two superposed normal curves with the same means and numbers of observations; if the standard deviation of the one is to that of the other in ratio greater than 2.236 : 1, the median has a lower probable error than the mean. The figure shows the critical distribution for which the probable errors of mean and median are the same.

In the absence of definite knowledge as to the frequency distribution of estimates in any specific case, it does not seem to me that any confident judgment as to choice of means can be given. G. UDNY YULE.

March 26.

Golden Carp attacked by a Toad.

THE following account of a toad attacking a golden carp may be of interest to some of your readers from its bearing on an ancient belief that frogs and toads are at enmity with carp, and kill them by destroying their eyes. Izaak Walton in the "Compleat Angler" refers to this belief,

and states that frogs attack carp by "sticking fast" to their heads. Possibly naturalists, unknown to me, may have already thrown light on the origin of a tale which hitherto I have regarded as a fisherman's story of the conventional type.

On March 29 my son directed my attention to a large golden carp (*C. auratus*) lying in shallow water near the edge of a pond in my garden with a frog or toad apparently resting on its head. The fish appeared to be very sluggish and made no attempt to escape from a landing net with which it was easily brought to shore. On examination it was found that the head of the fish was held tightly by a medium-sized common toad (*Bufo vulgaris*) which had obtained a very firm grasp by inserting its fore limbs as far as the second or elbow joint into the sockets of the eyes of the unfortunate fish. The ghoulish looking toad lay on the top of the fish's head facing its tail, and with its hind legs hanging in front of the fish's mouth. At first the appearance of the eyes of the fish led me to think they had been ruptured, but closer examination showed they were merely displaced and turned partially round owing to the pressure exerted by the intrusion of the toad's limbs between the eyes and their sockets.

On carefully withdrawing the toad's fore limbs, which were inserted to the extent of about 1 inch within the eye sockets, the eyes returned to their normal position apparently uninjured, but during their displacement the fish must have been quite blind. No effort of the fish could have rid itself of the toad after it had once obtained the remarkably firm grasp which has been described, and it appears very probable that the fish would have died in a short time. How the toad in the first instance obtained a hold in the sockets of the fish's eyes appears very puzzling, but a probable reason for its attempt to obtain a grasp, and for it holding on when a grasp was obtained, may perhaps be found in the unreasoning instinct which toads appear to possess at spawning time of grasping something firmly with their fore limbs. A few years ago in the same pond referred to above I found a toad embracing a water-logged puff-ball so firmly that it required considerable force to release the fungus from the amphibian's grasp.

The Atomic Weight of Nickel.

IN a recent number of NATURE (February 14, p. 367) Dr. Barkla gave reasons, based on experiments in connection with secondary Röntgen radiation, for assigning to nickel a new atomic weight. Dr. Barkla studies the penetrating power of secondary Röntgen radiation, shows that it depends on the atomic weight of the element, and from the values found for nickel in comparison with those found for copper and iron, he argues that nickel appears to have the atomic weight of 61.3 instead of the usually accepted value of 58.7.

Prof. McClelland (Trans. Roy. Dub. Soc., vol. ix., part i., 1905) showed that the intensity of secondary β radiation from different elements for the same exciting primary β rays depended on the atomic weight, and that a small difference in atomic weight could be detected in this way. According to Dr. Barkla, nickel has an atomic weight somewhat greater than cobalt, instead of the value slightly less, given by chemists. If this were so the intensity of the secondary β radiation from nickel should exceed that from cobalt.

I have recently repeated the observations of Prof. McClelland, using a very sensitive apparatus. Cobalt and nickel gave practically the same secondary radiation; if there is any difference, that given by cobalt is slightly the greater. The values found for these elements compared with those obtained for copper and iron correspond with their relative positions in the table of atomic weights. These results obtained with secondary β radiation do not, therefore, point the conclusion suggested by Dr. Barkla, and are in good agreement with the chemical determination of the atomic weight of nickel.

University College, Dublin.

Light Sense Organs in Xerophilous Stems.

IN view of the recent work of Haberlandt on the light sense organs of leaves, it may be of interest to record the discovery of similar organs in xerophilous stems. Certain of the epidermal cells of the young stems of the Ephedreæ have on their external wall conical structures of the nature of papillæ, the core of the papilla being mucilaginous. This structure acts as a collecting lens, focussing the incident rays of light, and a definite area of the cytoplasm of the back wall of the cell is thereby illuminated. Fig. 1, which is a photomicrograph taken

FIG. 1.—*Ephedra altissima* showing Light Spots.

in diffuse light of a mounted preparation of epidermis, shows the appearance of these light spots as seen under 1/6 objective.

Of any object held in the path of the incident rays an image is formed by each of these light sense organs.

Fig. 2 is a similar preparation to Fig. 1, but shows in each light spot the image of a hand held at a distance of about 2 feet in front of the microscope.

In the xerophilous Ephedreæ, where the assimilatory work is performed by the stems, and in correlation with

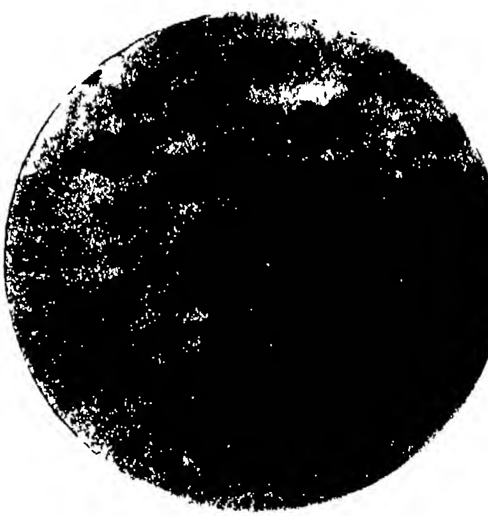

FIG. 2.—*Ephedra altissima* showing image of hand in each Light Spot.

which the histological character of the cortex is markedly similar to that found in the mesophyll of a leaf, the existence of such structures as these light sense organs so characteristic of leaves is not by any means unexpected.

An examination of other stems is in progress.

Botanical Department, University, St. Andrews, March 26.

THE LIVING WELWITSCHIA

IN the course of a botanical expedition[1] in Damaraland from Walfish Bay to Windhuk I spent some days in January and February in the littoral desert (the Namib), where in several localities Welwitschia is abundant. Speaking generally, the cones seen this year on January 22 and on later dates were considerably more advanced than those examined on January 15, 1904. The plants are flowering quite as profusely as they were three years ago, and, excepting a number of immature specimens, few were without cones.

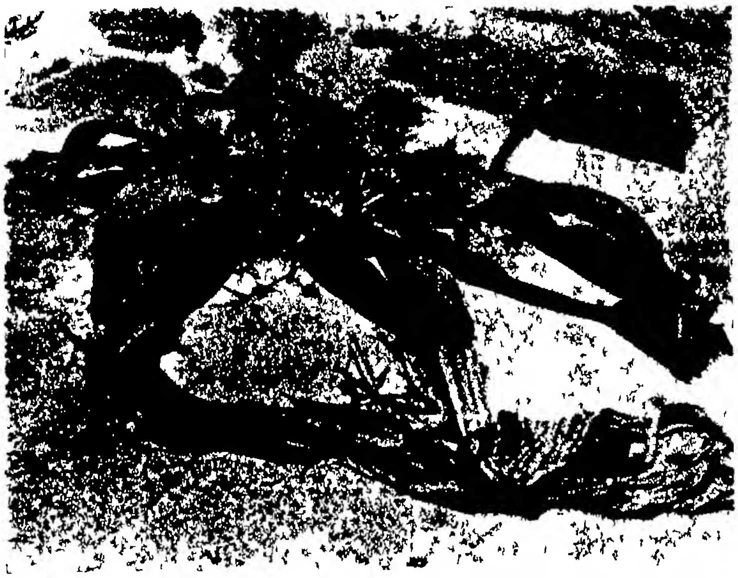

FIG. 1.—Welwitschia. Male Plant.

Fig. 1 shows a male plant the leaves of which are torn into broad bands. Baines might be forgiven for representing a plant not very different from this by the picture reproduced in Hooker's monograph (Plate i, Fig. 2). The tearing of the leaves into narrow strips which on the whole seems to be more characteristic is, I think, less common in the eastern part of the Damaraland area than in the west. The inflorescences (Fig. 2) compound dichasia with decussating branches, occasionally reduced to solitary sessile cones—are inserted in pits on the outer ridge of the stem just within the leaf base. The ridge in the axil of the leaf remains fertile for a number of years. The lower flowers of most of the cones seen in the photograph are open and their anthers are exserted.

The female plant shown in Fig. 3 bears an unusually large crop of cones. This is also an eastern plant, and the leaf-segments are few and broad. The bracts are deep, dull red in colour, except for a narrow margin of dark brown which extends for a short distance only on either side of the apex. The general effect is to mark out the four angles of the cone by longitudinal dark bands, which are separated by broader red bands along which the bracts overlap. In Fitch's picture (Hooker, Plate vii, Fig. 1) the angles of the cone are not sufficiently dark, and the colour of the remainder is too bright. The lower ovules appear to be pollinated. A drop of an intensely sweet viscous fluid was found on the summit of the projecting micropyle of each of the upper ovules during the day. It was not observed earlier than 9 a.m., but was common at 9.30 a.m. It remained there until after 3 p.m., but disappeared before sunset. Its formation was not due to a general increase in the turgidity of the plant, for it appeared before midday on inflorescences cut off in the early morning. Similar drops were seen under like conditions on all cones of corresponding size and colour.

I have elsewhere stated that the hemipteron *Odontopus sexpunctulatus* which in Damaraland is always found on the inflorescences during the hotter part of the day, is not a pollinating agent, and have inferred, contrary to the opinion of Schinz, that the relation between the insect and the plant is one of parasitism only. This statement, founded as it was upon too hasty observation, is incorrect. Fourteen specimens captured in different places, some from male and others from female plants, and examined microscopically were found in every case to bear pollen. The grains adhere singly or in masses to the smooth surface of the abdomen or are caught up among the short hairs on the limbs. I have observed that as the insect walks over the cone the abdomen is touched by the exserted anthers in the one case and by the fluid-tipped micropyle in the other. There can therefore be no doubt that Odontopus is an important pollen-carrier, though I believe, not the only one. The cones are also visited by a fly which is sometimes present in considerable numbers, and also by at least two species of Hymenoptera. In these cases the sweet fluid on the top of the micropyle is probably a source of attraction, but it

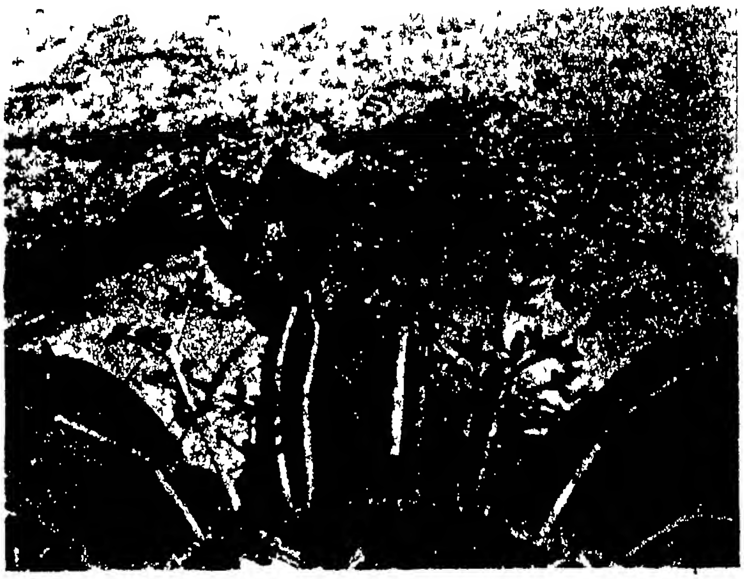

FIG. 2.—Inflorescences of Welwitschia.

[1] In part assisted by a grant from the British Association.

is less likely that it exercises a similar influence on the visits of Odontopus. It may be suggested that pollination was once mainly effected by insects in search of nectar, and that the relations which now exist between the plant and Odontopus have been more recently established. This is the more probable, since this insect is so widely distributed in regions where Welwitschia does not occur. Possibly the coloration of the bracts at the time of pollination is also connected with the process. Certain it is that before the micropyles appear above the bracts the latter are green, and the red colour appears about the time of pollination. Further, there is no trace of a red colour in the many old specimens of seeding cones that I have examined, but I have not been able to make sure that the colour disappears while the cone is still attached to the plant, though I believe this to be the case.[1] If this is so, the occurrence of yellow seeding cones in Hereroland specimens (as described by Pechuel-Losche) is at once explained.[1] The native in this picture (Fig. 3) is a Herero. The shrubs in the middle distance are Sarcocaulon sp.

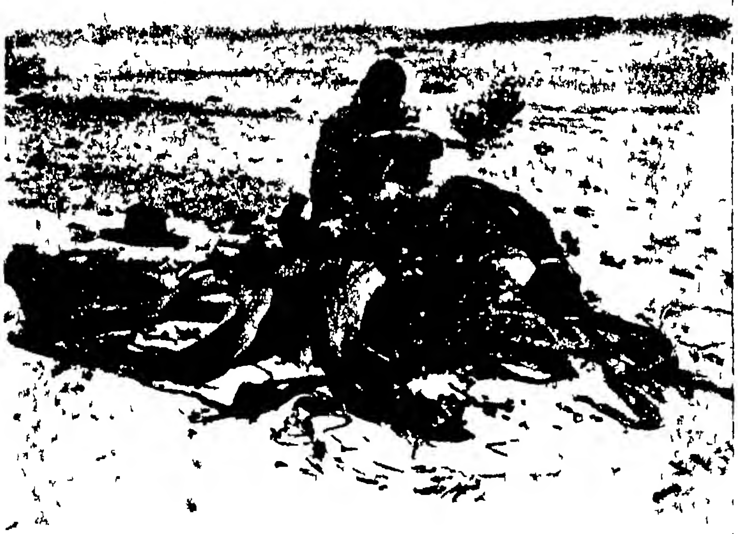

Fig. 3.—Welwitschia. Female Plant.

Through the kindness of Mr. K. Dinter, whose name is well known in connection with the botany of Damaraland, I was able to examine a bed of seedlings in the nursery of the forest department at Okahandya. The seeds were sown in July last in a deep, well-drained sandy soil, and germinated in about two weeks. A specimen which I was allowed to take up on February 7 had an exceedingly slender tap-root with a few short branches, the main root (the tip was left in the ground) measured 20.5 cm. below the feeder, the oldest branch being 11 cm. below the same level. The fairly stout hypocotyl was 2 cm. long, the foliage leaves 4.5 cm., the cotyledons were dry and shrivelled, and the lateral cones represented by small, vertically placed green lamellæ. The comparatively rapid elongation of the root, altogether out of proportion, on the one hand, to its own growth in thickness, and on the other to the increase in size of the aerial parts, points to the existence of a supreme necessity that the absorbing root should reach an underground source of water and as soon as possible render the plant independent of the very scanty and infrequent supply at the surface. In nature the conditions which would induce germination, and at the same time enable the root to penetrate the surface layers to a sufficient depth must very rarely occur, and it is not surprising that young seedlings have been searched for in vain. This apparent failure of natural reproduction by seed in recent years, when considered in relation to the large number of plants found within a comparatively small area and their obviously slow growth, suggests that the life conditions now prevailing in this Welwitschia area are more severe than formerly. There is other evidence also pointing to the same conclusion. Vegetative reproduction being entirely wanting, it is difficult to escape the conviction that, with the continuance of existing climatic conditions, the species, here, at least, is approaching extinction.

I am very deeply indebted to His Excellency Herr von Lindequist, Imperial Governor of German South-West Africa, and to Herr Regierungsrath Dr. Hintraeger, Acting Governor, through whose kindness every assistance which the Government could possibly give me in the study of Welwitschia and in a subsequent journey further inland was most generously afforded.

H. H. W. PEARSON.

THE ART OF EMBALMING IN ANCIENT EGYPT.[1]

PROF. ELLIOT SMITH has applied to the study of mummification the accurate and thorough methods of observation which have won for him a foremost place among the younger generation of anatomists, the result being an authoritative memoir which will serve both the expert and the uninitiated as an excellent introduction to the art and significance of embalming as practised in ancient Egypt. As professor of anatomy in the medical school at Cairo he has free access to the material necessary for a first-hand study of the subject. So well has he pieced his evidence together that one obtains on reading it a very complete picture of the actual process employed by the embalmers during the twenty-first dynasty. The memoir is based on a study of forty-four mummies of priests and priestesses of Ammon, belonging to that dynasty.

Although the chief object of the author was to unravel the details of the embalmer's art, he carefully collected all evidence which might throw light on the significance of a custom which was practised for a period of at least two thousand years in Egypt—from the seventeenth dynasty until about 600 A.D. During the twenty-first dynasty embalming culminated in an elaborate technique which aimed at preserving the integrity of the skin and restoring the living form to the body. In explanation of the elaboration of technique during this period, Elliot Smith brings forward a suggestion of Dr. Reisner (in charge of the Hearst Egyptological Expedition of the University of California), namely, that the procedure had as its object a life-like preservation of the body so that it might serve as an abode for the *Ka* or "double" in place of the statue which was usually placed in the tomb along with the dead body to

1 "A Contribution to the Study of Mummification in Egypt." By Prof. G. Elliot Smith. Pp. 53+plates. Mémoires présentés à l'Institut Égyptien et publiés sous les auspices de S. A. Abbas II, Khédive d'Égypte, Tome v. Fasc. 1. (Cairo, 1906.)

answer this purpose. Whatever the object may have been there can be no doubt as to the tedious and complicated nature of the means employed.

Before the twenty-first dynasty, the process of embalming resulted in a mummy which was simply a *skeleton wrapped in a wrinkled covering of shrivelled skin*. In this dynasty, or at the close of the twentieth, the process of packing or "stuffing" was introduced to avoid the shrivelling of the flesh and distortion of the body which marred the work of the older embalmers. The mortal flesh was replaced by subcutaneous packings of durable material, such as mud, sand, lime and sawdust, with occasionally, in addition, of aromatic vegetable substances such as onion. The eyes of the great Rameses IV. were replaced by onions. After the twenty-first dynasty the art of embalming declined. Subcutaneous packing was discontinued, the surface form of the body being restored by swathing the limbs and body by an artistic application of bandages; later still all distortion was hidden by a free application of pitch and bandage to the shrunken trunk and limbs.

In the course of his investigations Elliot Smith was able to verify certain statements made by Herodotus and by Diodorus Siculus concerning the methods of embalming employed by the ancient Egyptians. Herodotus describes the extraction of the brain through a small opening made on the roof of the nasal cavity, a procedure which Greenhill characterised as "amusing and impracticable." It was found that all the mummies belonging to the seventeenth and later dynasties showed clear evidence of the truth of the ancient description; early in last century, T. J. Pettigrew also verified it. In the writings of Pettigrew and in Brugsch's translation of the Rhind Papyri, the author of the memoir found much that assisted him in re-constructing the details of the process used by the embalmers. Broadly speaking, there were three stages: (1) the viscera were removed from the body through a wound in the left flank, the heart being invariably left in the trunk; (2) the body was then placed in brine for a period of thirty or forty days, the viscera were preserved in a similar medium within the four "Canopic Jars," each of which was dedicated to one of the four children of Horus; (3) after removal from the salt bath the body, now much shrunken, was packed. From the arrangement of the packing Elliot Smith found it possible to tell the exact manner and order in which this had been accomplished; it is unnecessary here to mention the details, but one may safely state that these ancient embalmers must have had a very considerable knowledge of the anatomy of the human body.

The process of packing was finished by returning the contents of the four canopic jars to the body cavity; they were arranged in four packages and were usually replaced within the cavity in a certain definite order. In each package it was the custom to enclose the image of one of the four children of Horus—"funerary genii," as they are named in this memoir.

The following statement of Pettigrew is quoted in this connection:—

"To Amset were dedicated the stomach and large intestines, to Hapi the small intestines, to Smautf (Tuamâutef) the lungs and heart, and to Kebhsnuf the liver and gall bladder."

On this Prof. Elliot Smith makes the following commentary:—

"The examination of a still larger series of mummies of this period (twenty-first dynasty) has convinced me that, in spite of frequent irregularities, a definite association was intended—but the guardianship of the various Genii is by no means identical with that suggested by Pettigrew. Thus the human *Amset* is usually found wrapped up in the *liver* instead of the stomach and large intestines, the ape-headed *Hapi* is usually associated with the *left lung* rather than the small intestines, the Jackal *Tuamâutef* with the stomach ... and the hawk-headed *Kebhsnuf* ... in the parcel of intestines."

There are many other points in this memoir which are deserving of notice, but enough has been said to show its value as a real contribution to our knowledge of the ancient Egyptians.

ASTRONOMICAL REFRACTION.

WHEN a ray of light passes through a medium of uniform density the path described is a straight line. Should this ray meet obliquely another medium of different density it is bent or refracted. If the second medium is more dense than the first, then the ray as it enters the second medium is refracted towards the normal, or that line at right angles to the tangential plane at the point where the ray enters the second medium.

In the case of astronomical refraction, the light, say, from a star, passes through space and then penetrates the earth's atmosphere, a medium which is in all parts denser than the space between the star and the upper limit of the earth's atmosphere. By the time the ray reaches the observer it will therefore be considerably bent towards the normal. If our atmosphere were homogeneous, that is, if it were of equal density throughout, the star's light would pass in a straight line from the point where it first penetrated it to the observer's eye. We know, however, that our atmosphere is far from being of uniform density, and one has not to climb a mountain or ascend in a balloon very high before this fact is made plain.

Up to a few years ago little was known with certainty about the physical conditions of the upper atmosphere, except the broad idea that the air became less dense the greater the distance from the earth's surface, and that at the same time the temperature readings were lower and lower.

This limited knowledge of our atmospheric conditions rendered it necessary to make some assumptions as to the law of decrease of density. This was imperative, because it was of vital importance to astronomers and mariners to know how much the ray of light from a celestial object had been bent after it had penetrated our aerial envelope. In fact, what was required was the difference between the apparent and actual direction of the heavenly body in the sky.

The assumption finally made was that the atmosphere consisted of a series of concentric spherical layers the common centre of which was the centre of the earth. Each layer was considered of uniform density, and these densities or temperatures and refractive powers all decreased as the surface of the earth was left behind, the amount of decrease varying in a prescribed way and agreeing in the main with the actual, but few, observations made in balloons and on mountain tops. On this assumption, then, the ray which entered our atmosphere was always meeting with denser and warmer layers of air, and gradually becoming more and more bent as each consecutive layer was passed through.

During the course of the last few years very rapid strides have been made in investigating the upper air by means of manned and unmanned balloons and kites carrying meteorological instruments, and eleva-

tions have been reached which formerly were impossible to attain. The data collected at various heights above the earth's surface have now, therefore, become considerable, and our knowledge of the distribution of atmospheric temperature has in this way been greatly advanced. Thus it is known that the temperature does not gradually decrease as greater elevations are reached at the rate that was previously assumed. In fact, numerous records from automatic instruments have shown that at some heights quite considerable rises in temperature, extending through large depths of atmosphere, have been noted, these inversions being far more common than was at first contemplated.

With this condition of things so prominently brought out, it is at once obvious that some attention should be paid to a possible revision of the assumption on which the theory of astronomical refraction is based, because the path of a ray of light traversing such variously heated layers may not be the same as that computed on the old hypothesis.

Fortunately, this question is now receiving some attention, and this is shown by a recent preliminary paper by Prof. H. G. van de Sande Bakhuyzen entitled "On the Astronomical Refractions Corresponding to a Distribution of the Temperature derived from Balloon Ascents," which appeared in the *Koninklijke Akademie van Wetenschappen te Amsterdam* (January 20).

In this investigation Prof. Bakhuyzen has employed observations made on 182 different days, of which fifty-eight were made with unclouded and 124 with clouded sky. The ascents were made from Hald (in Denmark), Berlin, Paris, Strassburg, and Vienna, so that the values which he gives for temperatures at heights from 0 kilometre to 16 kilometres apply to the mean of the area enclosed by those stations. The values for the means above 13 kilometres are, as he states, not very certain, but the observations indicate that the temperature at these heights decreases slowly.

As this table is of considerable interest, a portion of it may be given here:—

Temperatures (centigrade) at heights from 0–16 kilometres for clear weather.

Height	Annual mean	Diff
0	+ 6 4	1 1
1	+ 5 3	− 4 3
2	+ 1 0	− 4 8
3	− 3 8	− 5 5
4	− 9 3	− 6 1
5	− 15 4	− 6 4
6	− 21 8	6 7
7	− 28 5	− 7 3
8	35 8	− 7 4
9	43 2	− 6 4
10	− 49 6	− 5 1
11	− 54 7	2 3
12	57 0	1 0
13	58 0	− 0 6
14	58 6	− 0 4
15	− 59 0	0 2
16	− 59 2	

The result of this preliminary investigation shows that when the refractions for zenith distances greater than 85° have been determined, the values for these alone are given in the paper, the values deviate perceptibly from those deduced from Ivory's theory.

Even if great weight be not put on this result, the inquiry is one which should undoubtedly be taken up again when more data are forthcoming. The astronomer of to-day is perhaps inclined to look upon the results of the computation of refraction by methods at present in use as strictly correct, but evidently due regard must now be paid to new data rendered available by atmospheric soundings. The subject of Prof. Bakhuyzen's inquiry is therefore of considerable importance, and future research in this direction will be followed with interest.

NOTES.

IN the issue of the *Revue Scientifique* for March 30 are reprinted portions of the funeral oration delivered by M. Briand, the Minister of Public Instruction, at the national funeral of M. and Mme. Berthelot at the Panthéon on March 25. M. Briand, speaking of Berthelot, said:—"The illustrious man of science, the great Frenchman for whom we mourn, was one of those colossal men who are an honour to every country and every age. He thought it the duty of every citizen to interest himself in the affairs of his city, and that is why his life was so multiplex, why his activities were exercised in such various directions. Probably he would have preferred to give all his time to his laboratory and his favourite studies, but when the public interest called him, when it looked to him to place his science at the service of the national defences of education, of general politics, Marcellin Berthelot did his duty simply, and we have thus to celebrate to-day at the same time the man of science, the philosopher, the educator, the politician, and *l'honnête homme*." Toward the close of his oration M. Briand remarked that he had been called by his position "to the painful and formidable honour of rendering homage, in the name of the Government, to the man of genius for whom universal science is in mourning," he then proceeded to give a touching eulogy of Berthelot as a private individual. The discourse serves admirably to show the high esteem in which the French people and rulers hold their great men of science.

DR. NANSEN will give a paper on "Polar Problems" at the Royal Geographical Society on Monday, April 29; on May 13 a paper on "An Expedition from the Niger to the Nile" will be read by Lieut. Boyd Alexander.

AT the recent annual meeting of the Royal Irish Academy Prof. F. A. Tarleton was elected president for the session 1907–8, and the following were elected honorary members in the section of science:—Profs. Ramon Y Cajal, Madrid; W. Ostwald, Leipzig; E. C. Pickering, Cambridge (Mass.), U.S.A.; and H. Poincaré, Paris.

A REUTER message from Constantinople reports that considerable damage has been done to property at Bitlis by violent earthquake shocks on March 29.

ON Tuesday, April 9, Prof. G. H. Bryan, F.R.S., will begin a course of two lectures at the Royal Institution on "Wings and Aeroplanes"; on Thursday, April 11, Prof. H. A. Miers, F.R.S., will commence a course of two lectures on "The Birth and Affinities of Crystals"; and on Saturday, April 13, Prof. Silvanus P. Thompson, F.R.S., will begin a course of three lectures on "Studies in Magnetism" (the Tyndall lectures). The Friday evening discourse on April 12 will be delivered by Prof. A. H. Church, F.R.S., the subject being "Conservation of Historic Buildings and Frescoes," and on April 19 by Prof. C. S. Sherrington, F.R.S., on "Nerve as a Master of Muscle."

MR. ANDREW CARNEGIE has invited a large party of guests from England to attend the dedication of the new building of the Carnegie Institute at Pittsburg, Pennsyl-

vania A large contingent of the party left Liverpool on Wednesday last for New York by the White Star steamer *Baltic*, among them being Sir Robert Ball, Provost and Mrs MacBeth, Prof Rhys, Principal of Jesus College, Oxford, Mr and Mrs John Robertson, and Dr John Ross

THE death is announced of Prof J K Rees, formerly professor of astronomy in Columbia University, New York Prof Rees was for two years president of the New York Academy of Sciences, and for fourteen years secretary of the American Meteorological Society His principal observational research was a study of the variation of terrestrial latitudes and the aberration of light made in cooperation with the Royal Observatory Naples This work was continued from 1893 to 1900, and was the first application of the method of simultaneous observations at two stations situated on the same parallel of latitude, but separated widely in longitude It was during Rees's professorship that Columbia University undertook the publication of Rutherford's series of star photographs He also established the Columbia summer school of geodesy and early recognised that practical field work in this subject is an indispensable adjunct in the training of civil engineers

AMONG the scientific subjects for which prizes are offered by the Reale Istituto Lombardo we note the following —for the Cagnola prize, April, 1907 on the discovery of radio-activity and its influence on modern physical and chemical theories, for 1908 on the present state of metallography in relation to the physical properties of metals particularly iron and steel, a general summary including some original results for the Fossati prize for 1907, on the so-called nuclei of origin and termination of the cranial nerves, for the Kramer prize for 1907, a discussion with certain practical applications of Guglielmini's hydraulic theories, for the Secco Comneno prize for 1907, a discovery relating to the virus of rabies, for 1911, on the physiological action of high-frequency currents As in previous years, other prizes are offered for literary and commercial subjects and for subjects which are the same every year For the present year the prize awards of the Reale Istituto Lombardo include a Cagnola prize of 100*l* and medal of value 20*l* to Dr Augusto Moschini of Pavia for his essay on the pathology of the suprarenal capsules, a prize of 80*l* to Dr Guido Sala of Pavia and awards of 20*l* to Prof Domenico Lo Monaco and G Pitò, of Rome, for essays on the anatomy of the visual centres of higher vertebrates under the Fossati foundation and Kramer prizes of 80*l* each to Ernesto Canalli, of Naples and Mario Baroni of Milan for essays on the resistance of structures in cement

A REUTER message states that Mr Walter Wellman will again attempt to reach the North Pole by airship during the coming summer The expedition steamer *Frithjof*, which is now at Trondhjem is to be ready to leave Tromso with the expedition on board for Spitsbergen, on June 1 The party will consist of about thirty-five men, and will proceed at once to the expedition base at Dane's Island established last year, where three men are now living The balloon part of the airship *America* has been rebuilt in the ateliers of M Mallet, Paris The airship is 183 feet in length with a greatest diameter of 52 feet. Its volume is 265 000 cubic feet, and when inflated the lifting force will be 19 500 lb The car itself is 115 feet in length, of steel tubing remarkably light and strong The backbone of this car is a steel reservoir of equal length to contain 1200 gallons (6800 lb) of petrol for the motors The principal motor, a 60 to 70 horse-power Clement, works directly on two steel screws, 11 5 feet in diameter, placed at each side of the car. The proper speed of this airship is sixteen to eighteen statute miles per hour, and the fuel carried gives 150 hours of motoring at full speed, radius of action, more than 2250 miles, or nearly double the distance from Spitsbergen to the Pole and back again All the mechanical part is being thoroughly tested by weeks of running, and at Spitsbergen trials will be made in the air of the completed ship before attempting the voyage to the Pole It is intended to reach the expedition base at Spitsbergen the first week in June to have trials of the airship in July, and to start for the Pole in the latter part of that month, or in the first half of August

A CORRESPONDENT sends us from Reval, Russia, some interesting particulars concerning the life and work of Dr Jakob Hurt, the "keeper of Esthonian folk-lore," who died on December 31 1906 (old style), to the great grief of all Esthonians Dr Hurt was born on July 10 (old style) 1839 at Wõru-maal (Werro district), Põlwa parish In 1859-65, he studied theology in the University of Tartu (now Jurjew), and after some years as lecturer in the gymnasium of that town was elected pastor to the parish church of Otepaa, where he remained from 1872–80 As the Esthonian population in St Petersburg grew, Dr Hurt was called to minister in their native tongue in the Church of St John where the Esthonian congregation numbers now about 30 000 souls He remained there from 1880 1901 His literary work was so great that he sacrificed his pastorage and devoted all his time to the native literature In his early years he became keenly interested in this subject, and listened to old folks' chants and legends which he recorded and published under the title of "Vana Kannel"—the Old Harp These songs awakened a strong feeling among the people, and a collection began in 1888 which is now represented by 160 volumes of MSS Only two volumes have appeared and a third is in print as "Setukeste Laulud," or the songs of Setukesed The whole national collection of Esthonian folk-lore now include 60 000 records of superstition 52,000 proverbs 45,000 folk songs, 40,000 enigmas, and 10 000 folk-tales The death of a folklorist who could accumulate such a vast amount of material is a loss, not to the Esthonians alone, but also to the world at large The Esthonians were almost a dead nation when Dr F R Kreutzwald (1803–1882) published his "Kalewipoeg"—the Esthonian Homer's "Iliad"—which brought them to notice The number of Esthonians is about one million The limit of the Esthonian language extends from Reval (Tallinn) so far south as Walk in Livonia There are many settlements of Esthonians in European Russia Caucasia, Siberia, and in the United States Canada, and other parts of the world It will be a great loss to the world if the valuable material collected by Dr Hurt is not preserved for future publication, and every effort should be made to secure this result The English Folk lore Society would probably help in this matter, and other societies might also do something The sacrifice of the collection would be a misfortune to science as well as to the Esthonian nation

SOME observations which help to explain the frequent occurrence of anhydrite in beds of gypsum have been made by Mr Louis C Kemp and are described in a note received from his father, Mr W. I Kemp Mr Kemp finds that anhydrite is readily formed from gypsum in solution in steam boiler working at 60 lb pressure per square inch Having occasion to examine some of the boiler sludge, precipitated from the mine water which had been used i

the boiler, he found the sludge to be almost pure anhydrite in fine crystals, and was confirmed in his observation by Dr Gerald T Moody, to whom part of the sample was sent.

ARE there any instances of church bells having been cracked by sound waves produced in air by explosions or heavy firing? A note in the *West Sussex Gazette* of March 28 suggests that this happened recently in the village of Appledram, Sussex Three volleys were fired by a naval party of twenty-four men over the grave of a seaman buried in the churchyard On the evening of the same day one of the church bells, nearly six hundred years old was found to be cracked The firing party was only about a dozen yards from the belfry, and it is believed that the vibration caused by the three intense sound waves in rapid succession cracked the bell It is well known that explosions and heavy firing have often broken windows but we do not remember any case of a bell being damaged in this way No windows were broken in the Appledram church, so apparently the effect was not due simply to compression waves It would be interesting to know whether there are other cases of bells having been cracked in the way that glass globes are said to have been broken when set in violent vibration by sound waves

ON January 8 Prof Willis I Moore, chief of the U S Weather Bureau, was asked by a committee on agriculture of the House of Representatives at Washington certain questions in regard to rainfall and change of climate in the United States The actual questions and answers have been reprinted in pamphlet form and the information given by Prof Moore is to the effect that the climate has in no way changed during recent years With regard to the rainfall in Kansas Nebraska, and other States, a table giving the means for thirty years in periods of ten years, clearly shows that the aggregate amounts have neither increased nor diminished to any extent worthy of consideration The first and last ten years were periods of fairly abundant rainfall, while in the middle ten years there was a deficiency During the last few years there has certainly been an excess of rainfall in some districts, but Prof Moore pointed out that as long a period of drought may be looked for later on This very natural and valuable opinion appears to have given offence to some newspapers in Kansas as being injurious to the States in question, and likely to prevent the sale of land Time will show that the attack they have made upon Prof Moore is both unwise and unwarranted His evidence is at least the outcome of knowledge obtained from a study of the best materials available to the Weather Bureau

INTEREST in natural history is encouraged by a series of articles on the country month by month which is appearing in *Pearson's Magazine* In addition to an illustrated article on the nature-story of April, with notes on the birds and flowers of the month and a calendar of the chief natural history events, the current number contains a contribution on the fertilisation of clover This article gives an instructive account, with several striking photographs, of cross-fertilisation of white Dutch clover by bees, but the remark that clover plants are "wise in their day and generation" because their structure favours this process is, to say the least, misleading Human attributes are implied even more definitely in the remark, "One cannot fail to admire the clover for its broad mindedness in not only thinking of its own immediate well-being, but working and arranging for the future, that its progeny should be vigorous and healthy" It is a pity to use expressions of this kind when referring to the functions of flowers A story entitled "A Message from the Moon" describes how an advertisement was projected by a parabolic reflector from the earth to the unilluminated part of the moon's surface The idea is ingenious enough, but unfortunately the author and his illustrator make the usual mistakes about the crescent moon The pictures show the advertisement on the dark part of an old crescent moon setting in a night scene, whereas such a crescent can, of course, only be seen shortly before sunrise The author takes the same liberties with the moon's motions by describing the moon as rising at New York at night in crescent form with the advertisement visible upon it for "upwards of three hours and a half, that is, until the moon was well overhead" We advise the author and the artist to make a few observations of the rising and setting crescent moons, and they will soon learn that the positions in which they place our satellite can never be realised in nature

WE have to acknowledge the receipt of a copy of a "Catalogue of British Orthoptera Neuroptera and Trichoptera" (fifteen pages) by the late C W Dale, published by Messrs Harwood, of Colchester

Museum News (Brooklyn N Y) for March records the bequest by Mrs C H Polhemus to the museum of a number of pictures, bronzes &c of the estimated value of 8000l , together with a sum of money for the preservation and increase of the collection

FROM the British Museum (Natural History) we have received a copy of a "List of British Seed-plants and Ferns," price 4d The list, which has been drawn up by Dr Rendle and Mr Britten, excludes some introduced and all exterminated plants as well as many of the phases of Rubus, Salix, &c together with the Channel Islands flora Plants which, although introduced, appear to have become naturalised, are indicated by italic type

A COPY of the second edition of the illustrated penny guide to the Hull Municipal Museum compiled by Mr T Sheppard, the curator, has been received The collections date from the year 1823, and include, among other valuable specimens the type-skeleton of Sibbald's rorqual (*Balaenoptera sibbaldi*), prepared from a carcase stranded at Spurn in 1836 and named by Gray in 1847 A photograph of this skeleton forms one of the illustrations

THE histology and development of the divided eyes of certain insects form the subject of a paper by Mr G D Shafer in the Proceedings of the Washington Academy of Sciences (vol viii , pp 459–486) The first part is devoted to the histology of the compound eyes of such forms as Sympetrum, the dragon-flies of the genus Anax and the midges of the genus Callibætis, which are divided by a curved line into an upper light-coloured and a lower dark moiety while in the second the author discusses the development of the large facetted area of the eye of the first and third of these groups In the case of the "turban-eye of Callibætis, the formation of a superposition image on the proximal and an apposition image on the distal retinulæ enables the eye with the superposition image to see, although perhaps indistinctly, in dim light where the small-facetted, deeply pigmented eye would be useless As these turban-eyes are restricted to the males of these may-flies which seek the females during flight in the gloaming, their use is obvious

'Meristic Homologies in Vertebrates' is the title of a thoughtful article by Mr J S Kingsley in the February number of the *American Naturalist* As one of the difficul

ties of the subject, the author points out that whereas mammals have twelve cranial nerves, in frogs and other ichthyopsidans the number is but ten. Consequently, the question arises whether the two additional nerves in the mammal are not due to the inclusion of two segments of the amphibian neck in the cranium of the former. If this be admitted there is a strong *primâ facie* probability that the occipital condyles of the frog are not the homological representatives of those of the mammal. On the other hand certain phenomena in annelids lead to the conclusion that segments, or somites, may be intercalated in various parts of the body by means of budding. If such a process exist in vertebrates, we could readily account for the two additional pairs of cranial nerves (representing as many segments) in the mammal as compared with the frog, without interfering with the homology of their condyles. So far, however, as the author is aware, no such budding zone is known in any vertebrate, and the hypothesis must consequently be regarded as merely of a tentative nature.

To the February number of the *Zoologist* Mr. T. Southwell contributes notes on Arctic whaling in 1906. The take of right whales was very small, the total number being only seven (four from East Greenland, two from Davis Strait, and one from Hudson Strait), and it was only the high price of bone, about 2500*l.* per ton—that rendered the venture profitable. The most noteworthy feature is the capture of the four whales in East Greenland waters, where none had previously been taken since 1889. The capture suggests that there are more whales in these waters than is generally believed, their accessibility or otherwise being largely dependent upon the condition of the ice. The author directs special attention to the capture of four Atlantic right whales by the Harris whalers, and likewise to the arrival of a cargo of "bone" from the same species (regarded a few years ago as nearly extinct) at New Bedford. In the March number of the same journal Mr. A. H. Paterson, of Yarmouth, gives some interesting particulars of the flocks of wildfowl and other birds which visited Norfolk at the time of the great snowfall of last Christmas. No less than about sixty swans were observed at Breydon, the majority of which appeared to be whoopers, although at least one is believed to have been of the Polish species, and pochards were vastly more numerous than for many years past.

PART III. of the fifth volume of *Biometrika* was issued in February. The opening article is Mr. Raymond Pearl's "Biometrical Study of Conjugation in Paramecium," concerning which some correspondence took place in our columns last autumn (vol. lxxiv., pp. 465, 584, 608). The memoir is of great interest. It is found that conjugants are differentiated from non-conjugants not only in type, as was well known, but also in variability and in correlation. Conjugant types from various sources differ less *inter se* than non-conjugants. The dimensions of the two members of a conjugant pair are highly correlated, and it is shown that this is almost certainly due to the fact that the two must fit—to put the matter shortly—or else they do not adhere, and sooner or later separate. The significance of these important results is discussed with care in considerable detail. Mr. J. F. Tocher contributes an account of an anthropometrical survey of the insane in Scotland, carried out at the cost of the Henderson trust under his direction; stature and head dimensions were measured, and pigmentation noted, for more than 8000 cases in the Scotch asylums. The memoir is illustrated by maps, and the whole of the original data are reprinted, by permission of the Henderson trust, as a supplement. A short article by "Student" deals with a point of practical interest, viz. the fluctuations of sampling to be expected in counting with a hæmacytometer, and in similar operations. For example, in order to obtain pure cultures of a yeast, the fluid is diluted until it is estimated that every two drops contain on the average one cell; different flasks are then seeded with one drop each, and it is assumed that "the majority of those flasks which show growth are pure cultures." But the question arises, what actual proportion may be expected to be pure? The answer is, about 76 per cent., 19 per cent. will have been seeded with two cells, and the remainder with three or more. As no references are given in the article, we may point out that the series used as a limit to the binomial when one of the chances is very small, is not novel; it was deduced by Poisson ("Recherches sur la Probabilité des Jugements," § 81, p. 206), and has been discussed in detail, with illustrations, by Bortkewitsch ("Das Gesetz der kleinen Zahlen," Leipzig, 1898).

AN account of the mosses collected at Westende and Coxyde, in Belgium, on the dunes, sands, and reclaimed lands known as "polders," combined with a discussion of the physiological factors regulating their distribution, is contributed by Dr. J. Massart to the *Bulletin du Jardin botanique*, Brussels, vol. i., No. 6. About sixty species were collected, of which *Syntrichia* (*Tortula*) *ruraliformis* was the most characteristic and widely spread.

IN the report of the Government laboratories at Manila for the year 1905–6 the superintendent, Mr. P. C. Freer, reviews the general lines of research carried out in the biological, chemical, and serum laboratories; he also formulates a plan for the establishment of a marine biological laboratory, and raises the question of founding a medical school in the Philippine Islands. Incidentally, Mr. Freer insists upon the necessity, that is not always rightly appreciated, for systematic botanical and entomological work, seeing that correct identification of plants or animals is an essential preliminary to the prosecution of investigation on economic products.

IN *Petermann's Mittheilungen*, vol. iii., part ii., Prof. F. Hock presents the first part of a study of the phytogeographical boundaries and regions of northern Germany. Beginning with the vegetation of East Prussia, the author states that the eastern boundary of the beech and the western limit of certain plants of the moors and swamps lie in this province, so that it may be regarded as a transition district between Russia and north-western Germany. The botanical region of north-western Germany is contrasted with the adjoining botanical provinces of lower Saxony, Schleswig-Holstein, and the Netherlands, all the latter containing various North Atlantic species that are absent in north-western Germany.

UNDER the title of the "Century Plant," Prof. W. Trelease contributes an article on the more important species of Agave to the March number of the *Popular Science Monthly*, New York. The chief value of many of the Agaves grown in Mexico lies in the fermented liquors prepared from the sap. In the plains of Apam, south of the City of Mexico, the sap is collected from extensive plantations of *Agave atrovirens* to make "pulque." "Mezcal" is a liquor obtained by distillation in another part of Mexico from *Agave Tequilana* and other species; "sotol" is the product of plants of the liliaceous genus Dasylirion. Reference is also made to the varieties that furnish sisal-hemp and other fibres.

BOTANICAL survey work concerned with the mapping of the vegetation of a given area according to a plan which is the outcome of a method suggested by Prof C Flahault, of Montpellier, has attracted a small but energetic band of workers in the United Kingdom The latest survey prepared by Mr. C E Moss, dealing with the distribution of vegetation in Somerset, was published in the *Geographical Journal* (October, 1906) In the lowland areas Mr Moss traces the transition from dunes fixed by sea-couch grass, *Agropyron junceum*, and marram grass, *Ammophila arundinacea*, to dune ponds and dune pastures, and so to maritime farmlands In another sequence of associations, the salt marsh, at first settled with Salicornia, is converted into land suitable for growing osiers and tree willows Similarly, typical series of formations are described for the upland areas, which are as markedly characteristic and easily recognised, so that the present paper provides an admirable introduction to anyone taking up the subject

MESSRS CARL ZEISS, of Jena, have forwarded a copy of their price-list relating to large projection apparatus This list contains a brief reference to everything necessary for the projection of microscopic objects, transparencies placed horizontally or vertically, and opaque objects Some general information is also given as to selection of the optical equipment for special purposes

IN the Journal of the Royal Microscopical Society, Mr J W Gordon describes a top stop for the microscope This is placed in the Ramsden circle of the instrument, its effect being to cut off the central part of every beam of light In this way the advantages of a wide aperture are preserved, and the definition is improved, as is well shown by the photographs illustrating the paper This improvement is attributed to the fact that in an unstopped beam the central and marginal parts do not exactly form the same image, and the confusion thus caused is obviated by the stop To cut off the marginal rays would be merely equivalent to using a narrower aperture

RECENT progress in the industry of perfumery and essential oils is ably summarised in a report by Messrs A Haller and H Gault in the *Bulletin de la Société d'Encouragement* (vol cix, No 2) Commercial statistics show that as a result of theoretical chemical researches there has been equal progress in the manufacture of natural essences and in the preparation of artificial perfumes

THE Engineering Standards Committee has issued a second report (No 26, London Crosby Lockwood and Son, price 10*s* 6*d*) of the locomotive committee on standard locomotives for Indian railways Four additional types of locomotive have been included at the request of the Indian Railway Board, and at the request of the Secretary of State for India the locomotive committee has formed itself into a permanent advisory body

AN address on the duration of the coal reserves of the United States, delivered by Mr Marius R Campbell to the National Geographic Society at Washington, is published in the *National Geographic Magazine* (vol xviii, No. 2). He enumerates the coal areas of the various States, and shows that, while Pennsylvania produces the most coal, Montana has the largest coalfields The total amount of coal in the United States, exclusive of Alaska is estimated at 2,200,000 million tons If the rate of consumption of 1905 were maintained indefinitely without change, this would last for 4000 years, but if the constantly increasing rate which has marked the consumption during the past ninety years be maintained, the coal supply will practically be exhausted within a hundred years

MESSRS F VIEWEG AND SON have just published (pp 417, price 12 marks) a fourth edition, revised and enlarged, of Prof Albert Ladenburg's well-known "Vortrage uber die Entwicklungsgeschichte der Chemie von Lavoisier bis zum Gegenwart," the first edition of which appeared so long ago as 1869 The main value of the work lies in the careful historical treatment of the progress of chemistry up to the time of the introduction of the conception of valency To bring the account up to date, however, additional chapters have been written for the new edition dealing with recent advances in physical chemistry, and including the theories of mass action, heterogeneous equilibrium, tautomerism, stereochemistry, and solution, a review is also given of recent discoveries in organic chemistry A special feature of this history is the very large number of references given to the original papers

A THIRD edition of Prof H Rottger's "Lehrbuch der Nahrungsmittel Chemie" has just been issued by the firm of J A Barth, of Leipzig (pp xiv+901, price 16 marks paper covers 17 marks bound) This work, probably for its completeness the most concise treatise on the chemistry of foods yet written, has gained in Germany a very high reputation, the second edition having been exhausted in a little more than three years To the new edition a number of tables and an index of authors' names have been added and a very complete set of references is given to the latest papers in all departments of the subject Third editions have also been published by F Tempsky, of Vienna, of Franz von Hemmelmayr's 'Lehrbuch der anorganischen Chemie" and "Lehrbuch der organischen Chemie" (pp 237 price 3 krone, and pp 150, price 2 30 krone, respectively), these books are designed for use in the fifth and sixth classes of the Austrian Realschulen, and are of a purely elementary character

SINCE the list of forthcoming scientific books appeared in NATURE of March 14, Messrs Swan Sonnenschein and Co, Ltd, have announced that they have in preparation — "The History and Ethnography of Africa South of the Zambezi from the Settlement of the Portuguese at Sofala in September, 1505, to the Conquest of the Cape Colony by Great Britain in September, 1795" by G M Theal, "Thought and Things a Study of the Development and Meaning of Thought or Genetic Logic," by Prof J M Baldwin, 3 vols vol ii, "Experimental Logic," vol iii, "Real Logic", "The History of Philosophy," based on the work of Dr J F Erdmann, fifth German edition, revised by Dr W B Erdmann, edited by W S Hough, "Lectures in Humanism," by Prof J S Mackenzie, "Mental Pathology and its Relation to Normal Psychology,' by Prof Storring, translated by Prof T Loveday, "Physiological Psychology," by Prof W Wundt a translation of the fifth and wholly re-written German edition by Prof E B Titchener, vol ii, "The Student's Text book of Zoology," by A Sedgwick, F R S vol iii completing the work and new editions of "Elementary Text-book of Practical Botany for the Botanical Laboratory and Private Student" by Prof E Strasburger, English edition by Prof W Hillhouse, and 'Handbook of Mosses" by J E Bagnall

OUR ASTRONOMICAL COLUMN

COMET 1907*a* (GIACOBINI).—The results of numerous observations of this comet are recorded in No. 4162 of the *Astronomische Nachrichten*, wherein there also appears a set of elements communicated by Prof. E. C. Pickering. On March 11, at Vienna, Dr. Rheden found that the comet was of the eleventh magnitude, and had a diameter of 30″ with a central condensation.

No. 4163 (March 20) of the same journal contains a set of elements and an ephemeris computed by the discoverer of the comet, and, according to the latter, the position on April 4, at 12h. (M.T. Paris), will be

$$\alpha = 6h.\ 19.5m.,\ \delta = +1^\circ\ 8'.5,$$

a point situated in Monoceros, and lying nearly half-way between ϵ Orionis and Procyon.

EPHEMERIS FOR THE MINOR PLANET (588) [1906 T.G.].—An ephemeris for the minor planet (588), extending from March 23 to June 19, is published in No. 4163 of the *Astronomische Nachrichten* by Dr. Bidschof. At present the planet is apparently in the constellation Leo, near to 91 Leonis, and is slowly travelling in a north-westerly direction; its magnitude is about 14.0.

SEARCH EPHEMERIS FOR COMET 1900 III (GIACOBINI).—A continuation of the ephemeris for the 1907 re-appearance of comet 1900 III is given by Herr Scharbe in No. 4163 of the *Astronomische Nachrichten*. The ephemeris based on the assumption that perihelion passage will take place on June 8 extends from April 6 to May 16, and others, allowing for slightly different rates of motion of the comet, are also given.

THE SOLAR ECLIPSE OF JANUARY 13.—The most recent eclipse of the sun was observed as a partial eclipse at the Zi-ka-wei Observatory, and the results of the terrestrial magnetism, temperature, actinometric, and other observations appear in No. 1156 (March 23) of *Cosmos*. The magnetographs showed nothing abnormal, but as shown by the curves which are given in the paper, there was a decided decrease from the normal both in temperature and actinism. The former began to fall about fifteen minutes after first contact, and began to recover its normal value at about twenty-seven minutes after the maximum phase. An Arago actinometer was employed, and the effect of the moon's interposition was observed much sooner than in the case of the ordinary thermometer. The times of the first and last contacts and of the disappearances of several groups of spots were also recorded.

MAN'S PLACE IN THE UNIVERSE.—In an article appearing in the April number of the *Fortnightly Review*, Prof. Turner returns to the discussion of Dr. Wallace's views regarding the unique position of the earth in the universe. It will be remembered that Dr. Wallace advanced reasons for the belief that the earth was at the centre of the universe, and, occupying this unique position, was possibly the only inhabited sphere. But, as Prof. Turner now points out, the researches of Prof. Kapteyn and, more recently and definitely, those of Mr. Eddington (see NATURE, No. 1938, December 20, 1906, p. 182) have shown that we have to consider the question of *two* universes, and this renders Dr. Wallace's position untenable unless the assumption is made that the solar system is the centre about which both universes oscillate.

THE ASTRONOMICAL SOCIETY OF ANTWERP.—We have received the second annual report of the Société d'Astronomie d'Anvers, dealing with the work performed by the society during last year. This society was founded for the purpose of popularising the study of astronomy amongst the inhabitants of the town, and appears to be fulfilling its purpose in an exceedingly business-like manner. An observatory has been opened, and is regularly used by the members, and, with the assistance of the city authorities, a course of free lectures on elementary astronomy is being given. The summaries of the first eleven lectures are published in the report, and these indicate that they should prove most instructive and worthy of emulation.

WIRELESS TELEGRAPHY IN LONGITUDE DETERMINATIONS.—A series of experimental determinations of longitude between Potsdam and the Brocken made by Prof. Albrecht during 1906, has shown that wireless telegraphy may be usefully employed for this purpose between stations not connected by the ordinary telegraph. In this case the older method has been previously employed, so that the relative precision of the two methods may be compared. In general, the differences were found to be of the order of one-thousandth of a second, and were not modified by any variation of the amount of energy used. The duration of the transmission was negligible, but it was found that atmospheric influences were more effective than in the case of ordinary telegraphy (*La Nature*, No. 1765, March 23).

ANCIENT CHINESE ASTRONOMY.—In an interesting paper appearing in the *Revue générale des Sciences*, No. 4 (February 28), M. de Saussure discusses the astronomical records contained in an ancient Chinese canonical work dating back to before 2300 B.C., and from the discussion arrives at some striking conclusions concerning the antiquity of systematic astronomical observation in China. The chief conclusion is that prior to 2000 B.C. the Chinese possessed instruments and the complete theory of their equatorial astronomy, in which they presumably observed certain selected stars situated near to the equator, and from these observations deduced the apparent position of the sun, and hence the progress of the seasons. That the inhabitants of Britain and of Egypt possessed the astronomical knowledge and the means to attain the same end—although by somewhat different methods—at an equally early date has been already demonstrated by Sir Norman Lockyer.

PUBLIC HEALTH

THE thirty-fourth annual report of the Local Government Board, 1904–5 (Supplement containing the Report of the Medical Officer, price 4s., London, 1906) commences with a useful summary of its contents by Mr. Power. Appendix A contains the provisions of the International Sanitary Convention of Paris, 1903, and of the West Indian Intercolonial Sanitary Convention, 1904, many reports by the Board's inspectors, statistical tables, and summaries by Dr. Bruce Low of the diffusion of plague and of cholera throughout the world in 1904. *Inter alia*, we are informed that vaccination is being increasingly adopted, the abstentions for 1903 being 14.7 per cent. of births as against 15.2 per cent. for 1902, and still higher for preceding years.

Appendix B contains the auxiliary scientific investigations carried out for the Board. Dr. Klein has investigated the transmission of plague in the rat, particularly by feeding. Feeding animals with cultures of the plague bacillus mixed with food having failed to infect, Dr. Klein conceived that if the organism were first protected from the digestive juices by drying it with the food, infection might occur; this was found to be the case, and in animals so infected the dejecta probably teem with bacilli. It was also found that earth or sand to which plague bacilli had been added in the form of gelatin cultures retained its infectivity for six to eight weeks.

Dr. Houston contributes a report on the bacteriological examination of deep well waters and of upland waters. The first section shows that *B. coli* is absent from 1000 c.c. of deep well water drawing its supply from distant and pure sources. The second section deals with the results of the examination of the waters of Loch Laggan and Loch Ericht (Inverness-shire). Loch Laggan is subject to a slight degree of pollution from human sources, Loch Ericht is not, and bacteriologically *B. coli* was contained in 10 c.c. in 33 per cent., and in 100 c.c. in 49 per cent., of Loch Laggan samples, while of Loch Ericht samples only 1 per cent. contained *B. coli* in 10 c.c. and 19 per cent. in 100 c.c. Dr. Houston therefore concludes that fish (of which the lochs contain abundance) and birds probably contribute little to the content of *coli*-like microbes, and that too stringent standards must not be adopted without topographical data.

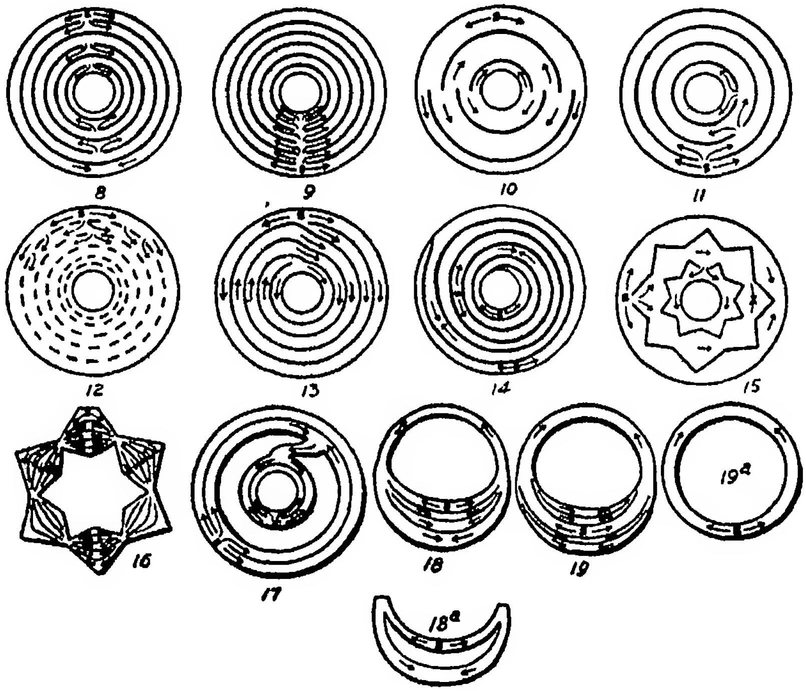
Dr. Sidney Martin has investigated the chemical products of the *B. enteritidis sporogenes*, but finds them to be without physiological action, also the specific agglutinins of various organisms.

Dr Gordon has sought for a bacteriological test whereby particles shed from the skins may be detected in the air He finds that a Staphylococcus (*S epidermidis albus* of Welch, with certain attributes) is by far the most frequent organism of the skin, and another Staphylococcus of the scalp Lastly, Dr Alan Green records further experiments on chloroformed vaccine lymph and on the combined use of chloroform and glycerin in preparing lymph The volume, therefore, contains much valuable matter, and is illustrated with a number of photographs

R T HEWLETT

PULSATION IN ANIMALS [1]

JELLY-FISHES have been the subjects of frequent experimentation—we need only refer to the admirable researches of Romanes—and Mr Alfred G Mayer, director of the Department of Marine Biology of the Carnegie Institution of Washington, has been able to draw some new and exceedingly interesting general conclusions from a study of their pulsations When the marginal sense-organs of the jelly-fish Cassiopea are cut off, the disc is paralysed and does not pulsate in sea-water If a ring-like cut, or a series of concentric broken-ring-like cuts, be made through the muscular tissue of the sub-umbrella, the mutilated disc (without marginal sense-organs) responds to a momentary stimulus, *e g* a mechanical or electrical shock, or a single touch with a crystal of potassium sulphate, and suddenly springs into unusually rapid rhythmical pulsation This is regular and sustained like clockwork and continues indefinitely in normal sea-water without further external stimulation The waves of pulsation all arise from the stimulated point, and the labyrinth of sub-umbrellar tissue around this centre must form a closed circuit—the stimulus being transmitted by the diffuse nervous or epithelial elements of the sub-umbrella Any cut that breaks the circuit stops the waves of pulsation, and continuous movement cannot again be started When each wave in a complete circuit returns to the centre it is reinforced and again sent out through the circuit The centre once established remains a fixed point, while the disc continues to pulsate The pulsation is fully twice as rapid as that of a normal Medusa, its rate varying with the length of the circuit, and it is self-sustaining (*i e* sustained by internal stimuli) once it be started by an external momentary stimulus



Shapes cut from discs without marginal sense-organs These will pulsate continuously in sea water The arrows indicate the paths of the waves of pulsation

Mr Mayer has endeavoured by numerous experiments to discover the *rôle* of the various salts in the sea-water and he finds that the sodium chloride is the chief stimulant to pulsation in Cassiopea, while magnesium is the chief restrainer of pulsation, and counteracts the influence of the sodium chloride Similarly, the heart of *Salpa democratica*, the heart of the embryo loggerhead turtle, and the branchial arms of the barnacle pulsate actively in solutions (*e g* Ringer's) containing only common salt, potassium and calcium, magnesium being absent Magnesium inhibits pulsation in all these cases Thus the general *rôle* of NaCl, K, and Ca in these cases is to combine to form a powerful stimulant producing an abnormally energetic pulsation, which, however, being exhausting cannot continue indefinitely, and magnesium is necessary to control and reduce this stimulus, so that the pulsating organ is merely upon the threshold of stimulation More concretely, the NaCl, K, and Ca of the sea-water unite in stimulating the pulsation of the jelly-fish, and in resisting the stupefying effect of the Mg, the general anaesthetic effect of which has been well known since the researches of Tullberg in 1892 All four salts conjointly produce in sea-water an indifferent, or balanced, fluid which neither stimulates nor stupefies the disc (*i e* the medusa with marginal sense-organs excised), and permits a recurring internal stimulus to produce rhythmic movement

Not only has the author shown us a new method of restoring pulsation in paralysed Medusæ, but he has demonstrated that magnesium plays a most important *rôle* in restraining, controlling, and thereby prolonging pulsation in animal organisms "Rhythmical pulsation can be maintained only when a stimulus and an inhibitor counteract one another, and cause the organism to be upon the threshold of stimulation, thus permitting weak internal stimuli to promote periodic contraction" Thus, once more, marine biology justifies itself in contributing to the progress of general physiology

THE WEATHER AND THE CROPS

AN interesting paper on the correlation between the weather and the crops, by Mr R H Hooker, head of the statistical branch of the Board of Agriculture was read before the Royal Statistical Society on January 15

The subject is very fully discussed by the method of correlation partial coefficients of correlation being determined between the produce of each crop and (1) the rainfall, (2) the accumulated temperature above 42° F during successive overlapping periods of eight weeks (first to eighth weeks of the year, fifth to twelfth, and so on) The crops dealt with include wheat, barley, oats, beans, peas, potatoes, turnips and swedes, mangolds, hay from clover and rotation grass and hay from permanent grass As climatic conditions differ so materially in England and Scotland and even in different parts of England, it was thought necessary to deal with a smaller area, and a group of eight

of the eastern counties was chosen for the purpose. The group includes the county with the largest acreage under each of the ten crops named, with the single exception of grass.

The results for wheat are of especial interest in connection with Dr. Shaw's conclusion as to the great importance of the autumn rainfall. Mr. Hooker confirms this, and finds, further, that the autumn is more important than any other period. The critical period is, however, probably somewhat shorter, the correlation of the produce with rain exhibiting a marked negative maximum for the thirty-seventh to forty-fourth weeks, the actual coefficient being −0.62; the coefficient with the rainfall of the cereal year as a whole is slightly greater still, viz. −0.69. There are two marked coefficients with the weather of the preceding summer, i.e. the summer of the year in which the seed for the crop was grown, viz. −0.49 with rain during the twenty-first to twenty-eighth weeks, and +0.51 with temperature for the twenty-ninth to thirty-sixth weeks, indicating absence of rain during the flowering period and warmth at harvest as necessary for good seed. For barley the chief requirement appears to be a cool summer, and for oats the same thing holds, but the latter crop also demands rain in spring, as indicated by a coefficient of +0.70. In the case of turnips, the highest coefficient, +0.55, is with the rainfall in June–July, i.e. the sowing season, this being partly due, in all probability, to the fact that in a dry season the turnip-fly will eat off a young crop almost as soon as it shows above the ground. In spite of prevalent opinion there does not seem to be any need for rain in late summer. In the case of the hay crops, the great value of the rainfall in spring and early summer is very well brought out, the coefficients attaining sharply marked maximum values of more than 0.7 in the spring.

One conclusion of remarkable generality is reached, viz. the advantage of cool weather during the late spring and summer for all the crops dealt with (except, perhaps, potatoes). Taking the period between the ninth and twenty-eighth weeks of the year, all the four coefficients with temperature are negative in the case of barley, oats, turnips, mangolds and hay; for wheat and for beans three of the four coefficients are negative. The correlation is with cool weather as such, and not with rain, as the effect of rain is practically eliminated by the method used. The result seems to indicate that grain and roots yield the most bulky crops if developed gradually and equably; neither rains nor heat, in fact, seem to be good for the crop for some time before harvest.

The paper also brings out very clearly another fact, viz. that the condition of the seed sown may be as important as the subsequent weather. As the condition of the seed is itself dependent on the weather of the year during which it was grown, this gives rise to the observed correlations between the crop and the weather of the seed year as well as that of the harvest year. Further, the meteorological conditions necessary for seed quality appear to be broadly speaking somewhat opposed to those necessary for a bulky crop. Thus, in the case of wheat, absence of rain during the flowering period and warmth at harvest were found to be necessary for good seed, but for a bulky crop cool weather is desirable. Considering all the coefficients with temperature for the ninth to thirty-sixth weeks, for wheat only one out of six is positive in the harvest year, five in the seed year; for barley none is positive in the harvest year, five in the seed year; for oats none in the harvest year, four in the seed year. This result would by itself suffice to account for the tendency observed in the case of cereals to an alternation of good and bad crops.

Although there is considerable uncertainty in some of the less well-marked results owing to the small number of observations available (twenty-one years), the application of the laborious methods used appears to have fully justified itself by the conclusions which have been thereby reached. How great the labour must have been may be judged from the number of correlation coefficients—between six and seven hundred—which have been tabulated by the author. The paper is published, with an abstract of the discussion which took place at the meeting, in the Journal of the Royal Statistical Society for March.

FLAME THE WORKING FLUID IN GAS AND PETROL ENGINES.[1]

FLAME produced by the combustion of inflammable gas or vapour and atmospheric air forms the working fluid of gas or petrol engines.

Mechanical power can be obtained by means of flame in several different methods:—

(1) By filling a vessel or cylinder with a mixture of gas and air, and igniting this mixture, a slight explosion is caused, and the excess pressure blows off through a valve. The temperature of the flame is very high, and so when it cools the pressure in the vessel is reduced below atmosphere. This reduction of pressure may be utilised by means of an engine operating by atmospheric pressure and discharging into a partly vacuous vessel, or by a piston moving into the vacuous vessel. This method may be called the explosion-vacuum method.

A modification of this method exists which may be called the flame vacuum method. In it the explosion is dispensed with.

(2) By admitting a charge of atmospheric air and inflammable gas or vapour at atmospheric pressure to a cylinder containing a piston, cutting off access to the atmosphere and the gas supply, and igniting the mixed charge, a mild explosion occurs; the pressure rises in the cylinder, and the piston is driven forward to the end of its stroke.

(3) By supplying to a cylinder containing a piston a mixture of inflammable gas and air in a compressed state and then igniting that mixture, a motive power can be obtained.

These last two methods, (2) and (3), are respectively known as the non-compression method and the compression method of operation in gas and petrol engines. The two methods were illustrated by a specially constructed apparatus. In this apparatus the cylinder of a petrol engine was mounted so that the piston reciprocated vertically, and a guide rod was fixed vertically on the cylinder. A hundred-pound weight was arranged to slide on this guide rod, and arrangements made by which a given charge of gas could be introduced into the cylinder. It was also arranged that the weight could be let down on to the piston, firstly so as to rest without compressing the charge, and secondly allowing compression of about 10 lb. per square inch. The mixture in the cylinder was ignited and, in the case where the charge was not compressed, the weight was thrown up by the explosion and expansion a distance of about 10 inches. In the case where the charge was compressed, the weight was thrown up about 18 inches, showing clearly the increased effect of the explosion of a given charge when under compression.

It is believed that this is the first time the effect of compression has been shown as a lecture experiment.

(4) A cylinder is supplied with gas and air under pressure, but the mixture is ignited at a grating or shield as it enters the cylinder, and so the pressure in the cylinder never rises above the pressure at which it is supplied. The power here is obtained without any increase in pressure, and is due to the fact that a small volume of cool mixture, when inflamed, becomes a larger volume, so that although a pump may be used to compress mixture the expansion in the motor side is greater, although at the same pressure as the pressure in the pump.

These four modes of action were all illustrated by means of specially constructed apparatus, in which the effect of the working flame could be seen. The four modes of action, and combinations or modifications of them, include all the fundamental methods used in obtaining motive power from flame which have been attempted by mankind for the last hundred years. In the year 1820 the Rev. W. Cecil, of Cambridge, read a paper at the Cambridge Philosophical Society in which he described an engine which he had constructed to operate according to the explosion-vacuum method, and he states that at sixty revolutions per minute the explosions take place with perfect regularity. His engine consumed, he stated, 17.6 cubic feet of hydrogen gas per hour. He also mentions an engine operated in accordance with the second method, the non-compression explosion method, and one

[1] Abstract of a discourse delivered at the Royal Institution on Friday, February 22, by Mr. Dugald Clerk.

also operated by gunpowder This paper gives an account of the first gas engine which appears to have been worked in Britain or elsewhere

Six years later Samuel Brown invented and built an ingenious engine, depending on the flame-vacuum method, which appears to have been the earliest gas engine ever worked on any considerable scale In an early number of the *Mechanics' Magazine* it is stated that Brown succeeded with his engine in propelling a boat upon the Thames and in actuating a road locomotive This vacuum method, however, never produced a really commercial engine, its only survival being the small engine shown as illustrating a modified form of class (1)

Many engines have been built using the atmospheric, or, as it is more commonly known, the non-compression explosion principle, but the most successful was that of Lenoir The simplest engine of this type was one which was used in considerable numbers until a comparatively recent date—the Bischoff engine In it a mixture of gas and air is drawn into the cylinder through suitable valves As the piston passes an igniting aperture the flame is sucked in, the mixture ignites, and a small check valve closes the flame or touch-hole aperture In the Lenoir engine, which was the most successful of this type, however, many of the modern characteristics are found such as the water-jacket and ignition by the electric spark The gas consumption, however, of all these engines was very high, rather more than 90 cubic feet per indicated horse-power per hour The power obtained for given dimensions, too, was very small

The first and second methods accordingly are not now used Their disadvantages proved too great In all modern gas or petrol engines the third method is used that is, the charge of inflammable mixture is compressed before ignition

Many attempts to construct engines operating on the compression principle were made before success was obtained In such attempts England had a full share One of the very earliest feasible compression gas engines was that described by William Barnett, an Englishman, in the year 1838 This engine had many of the features of successful engines of to-day Later proposals were made for similar engines, both in France and in Germany, but the first inventor to succeed in overcoming difficulties to a sufficient extent to produce a commercial engine was the late Dr Otto of Deutz To Dr Otto belongs the honour of producing the first successful compression gas engine The great majority of modern gas and petrol engines operate on what is now known as the Otto cycle The production of a compressed charge in a motor cylinder in a safe, quiet, and economical manner is a much more difficult problem than appears at first sight Those of us upon whom fell the brunt of working out this problem about thirty years ago appreciate fully the ability and knowledge displayed by the late Dr Otto in producing his famous engine In the Otto engine the characteristic feature is found in the alternate use of the same piston and cylinder for the purpose of pump and motor In one complete revolution the cylinder is used as a pump, and in another complete revolution as a motor The cycle is very simple

The Otto cycle has many great advantages The charging and discharging of the gases is accomplished easily The heat flow through the sides of the cylinder is not too continuous and consequently the cycle can be operated at very high speeds Many attempts, however, have been made to obviate the main disadvantage of the Otto cycle, that is, the necessity for two complete revolutions for every power impulse In 1881 the lecturer invented a cycle of operations which gave in the same cylinder one power impulse at each revolution This cycle is now known as the Clerk cycle and it comes next to the Otto cycle in order of number of engines now running in the world Sections showing the operation of the Clerk cycle were shown Its characteristic consists of open ports at the outer end of the stroke which are overrun by the piston The pressure in the cylinder rapidly falls to atmosphere, and a charge is forced into the cylinder at low pressure, about 2 lb above atmosphere This displaces the exhaust products remaining in the cylinder, and furnishes the fresh charge, which is compressed on the return stroke into a space at the end of the cylinder This charge is ignited, and in this way a power impulse is obtained for every forward stroke of the piston A second cylinder is required in order to supply the charge The second cylinder is very light in construction, both as to the cylinder itself, the piston, and the connecting rod and cranks driving it Working sections of a Clerk engine and Lanchester engine were shown

The last thirty years have seen the greatest development, so far as practical matters are concerned so that now more than two million horse-power of stationary gas engines operated by flame are in use in the world It is difficult to form an estimate of the power of motor-car engines in use but probably it now exceeds a million horse-power

Although great progress has been made in the practical control and utilisation of flame and gaseous explosions for the purpose of producing motive power, little is as yet known as to the actual properties of the flame working fluid so utilised Accordingly, for the present it is not possible to formulate a complete theory of the internal-combustion motor The subject is a difficult one, and involves not only the statical properties of these gases but requires a knowledge of the conditions and rate of chemical combinations occurring in minute fractions of a second, and of the conditions of dissociation of compounds such as carbonic acid and steam at high temperatures under varying conditions of temperature and pressure Many distinguished investigators have given the subject some attention Bunsen in 1866 arranged a small glass tube with a safety valve, and weights to apply pressure to the valve He provided platinum points between which the electric spark could be passed the whole length of the tubular vessel This vessel was filled with various explosive mixtures and ignited by the spark The valve was loaded until it just blew off This blow-off pressure was considered to be the maximum pressure produced by the explosion Bunsen's apparatus was very crude, and could not have been expected to give accurate results The maximum pressures must have far exceeded the pressures registered by his apparatus Messrs Mallard and Le Chatelier and Berthelot and Vieille took up the subject of gaseous explosions, and made experiments also with numerous gases and oxygen, and coal-gas and air A series of experiments was made by the lecturer in 1883 A Richards indicator, of the best construction known at that date, was used and secured indications which were fairly trustworthy Curves of explosion and cooling with coal-gas so obtained were shown These experiments also showed clearly that the whole of the heat present was not evolved at maximum temperature assuming the gases to have their ordinary specific heat at the high temperatures as well as low Messrs Mallard and Le Chatelier and Berthelot and Vieille had come to the conclusion that the specific heat of the gases had been changed, and they considered combustion to be complete at the maximum temperature or nearly so The lecturer's experience with engine indicator cards supplementing the experiments made with gas and air mixtures in a closed vessel led to the view that combustion was not complete and that therefore it was not safe to draw deductions as to varying specific heat without quite definite knowledge that chemical combination was completed before determinations were made of specific heat value The absence of definite knowledge as to specific heats at high temperatures, dissociation and rates of continued combustion, made it impossible to develop any complete theory of the internal-combustion motor

To enable some investigation, however, to be made on different engine cycles it appeared desirable to consider the gas engine as an air engine pure and simple operated with air of constant specific heat the air being a perfect gas and the chemical action being assumed as merely a means of heating the air through the desired temperature range Calculating on this simplified theory it became evident that the efficiency to be obtained in an air engine without heat losses was dependent upon compression mainly Working out this theory showed that while the utmost that could be theoretically expected from a non compression engine of the Lenoir type was 22 per cent compression supplied means of getting theoretical efficiencies as high as 60 per cent, with practicable ranges

of compressions Considering, then, gas and petrol engines as air engines, the theory is very simple There are three symmetrical cycles of compression air engines It is interesting to note that for equal compressions it does not matter whether Carnot cycle, constant volume, or constant pressure engines be used—the theoretical efficiency is the same It has been found in practice that a first-class modern engine operating on the constant-volume cycle will give in indicated power 0·7 of the heat which a perfect air engine would give under the same conditions of compression, proportions, &c Thus an engine having an air-engine efficiency of 0·5 will give indicated work 0·5×0·7=0·35, of all the heat given to it

The air standard has proved its utility as a guide to the engineer for twenty-five years now, and has been adopted by a committee appointed by the Institution of Civil Engineers on the standards of efficiency in internal-combustion engines. To enable further progress to be made, however, it is now necessary to know more of the actual properties of the working fluid

The earlier experiments made by the lecturer, and subsequent experiments made by Oliver in America, and by Messrs Bairstow and Alexander in this country, were only in strictness applicable to the behaviour of highly heated gases in a closed vessel No means of obtaining a cooling curve in an engine cylinder had been proposed

At the beginning of 1905 the lecturer designed a new method, and made a considerable number of experiments on a 50-horse-power gas engine By altering the valve arrangements of the engine so that when desired both inlet charge valve and exhaust valve can be held closed, diagrams were obtained from which a cooling curve was calculated

In this method no gases are allowed to exhaust from the cylinder The piston accordingly compresses the whole contents into the compression space, and the temperature which has fallen by expansion rises by compression A point is touched on a vertical line from the end of the card On expanding, a line below the first compression line is traced, then another compression line is obtained, and so on, a series of compression and expansion lines is obtained each terminating under compression at certain specific points

In this way a cooling curve is obtained which shows the real temperature drop upon the expanding and compressing lines From this curve, by somewhat troublesome calculations the mean apparent specific heat of the charge can be obtained for each expanding line A curve of specific heats so obtained was shown

These numbers give a very fair indication of the heat loss incurred in the cylinder, and the cooling curves show that for the whole stroke the mean temperature of the whole enclosing walls is about 70° C when the water-jacket is cold and about 200° C when the water-jacket is hot, but for the inner part of the stroke, the first three-tenths of the stroke, the mean temperature is much higher —170° C when cold and 400° C when hot

This method of investigation gives a more accurate knowledge of the properties of the working fluid so far as the thermodynamics of the engine are concerned, and it enables us to make an entire heat balance sheet from the diagram only Full load diagrams taken from the engine have been examined by this method, and account for 105 thermal units, when the calorimeter shows 106 thermal units to be present The method appears capable of very considerable accuracy

Prof Hopkinson has attacked the problem of heat loss to the closed vessel by another method using a calorimeter by which the heat leaving the hot gases at any time is measured electrically, while at the same time the pressure is indicated This arrangement promises to give important information as to the rate of loss in gaseous explosions, from which observations some deductions may be drawn as to specific heat and as to time of termination of combustion

The lecturer is continuing investigations on various sizes of engines with a new form of optical indicator An indicator card taken with this instrument was shown The appearance of this indicator card is most interesting There is slight discontinuity in the rising line, and just as maximum pressure is approached the indicator begins to oscillate rapidly through a small distance These oscillations continue all down the explosion stroke, die out gradually, and do not terminate until the end of the compression stroke The period of the oscillations is about 600 per second, the amplitude gradually decreases until it has practically ceased at the end of the first compression.

The period of the indicator is about 200 to the second, so far as ordinary piston displacement is concerned From this it follows that considerable pressure disturbances within the cylinder must have occasioned the oscillation In this particular engine, the explosion is always accompanied by a peculiar whistling sound, which seems to start just about the time the diagrams show the beginning of the oscillations, that is, immediately after ignition It is somewhat difficult to account for this peculiar action, but it appears to have some connection with the discontinuous nature of combustion of a mixture of inflammable gas or vapour with air This was illustrated by an experiment in which inflammable mixture was ignited at the open end of a long tube The flame travels back along the tube accompanied at first by a low, roaring sound, which increases in intensity as the end of the tube is reached, terminating in a loud snap When this occurs, the flame flashes back again, and there is obvious oscillation of some kind proceeding It is not known why the mixture flame burns in this way, but this particular roaring or whistling seems to occur only when combustion is going on, and is noticed in all pressure flames in the open air It appears highly probable, then that wherever this oscillation goes on combustion is still proceeding

Experiments have also been made by Messrs Holborn and Austen on the specific heat of air and carbonic acid by an entirely different method, and there is reason to hope that as a result of experiments which are progressing in this country and on the Continent the whole question will be cleared up in the next few years in a satisfactory manner

As one who has given thirty years' study to the practical and scientific problems involved in this matter, it is exceedingly gratifying to find a great and increasing interest in the subject which will lead to the complete investigation of the complex properties of the working fluid

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Dr W Peddie, lecturer in natural philosophy in the University of Edinburgh, has been appointed to the Harris chair of physics in University College, Dundee, in succession to Prof Kuenen

Prof Miall, F R S, who was appointed professor of biology in the Yorkshire College of Science in 1876, is retiring from his chair in the University of Leeds at the end of the present session We understand that the council has decided to establish separate chairs of zoology and botany, and will shortly proceed to appoint professors of these subjects

The province of Saskatchewan is only eighteen months old, but already (says the *Times*) it is devoting its resources to the establishment of a State university A Bill just introduced by the Provincial Government in the Legislative Assembly at Regina provides for the incorporation of such a university under a chancellor, convocation, senate board of governors, and council The number and nature of the faculties to be established will be decided by the university senate The maintenance of the university is to be provided out of the general revenues of the province and also by a percentage of the net receipts of the province under the Succession Duties Ordinance.

There has been serious divergence of opinion for more than two years as to the policy of the Marine Biological Association of the West of Scotland This association was founded in order, according to the first article of its constitution, to investigate the marine fauna and flora of the Clyde sea area, to maintain a biological station at Millport or other suitable locality, and generally to foster and encourage biological research At the annual meeting of the association on March 27 an amendment was carried by a majority of one vote "that while approving generally

of the report, the meeting does not approve of the staff being employed in biological survey" The chairman Dr. Rottenburg, Prof Bower, Prof Graham Kerr, Prof Lawrie, Dr Teacher, Mr F J Bles, Mr Todd, the honorary secretary, and other members of the general committee then tendered their resignations and withdrew from the meeting.

The council of the Association of Teachers in Technical Institutions recently appointed a committee to report upon the mathematical syllabuses of the Board of Education, and the recommendations of the committee have been embodied in an "outline of suggested syllabuses" which has been sent by the council to the Secretary of the Board of Education Several principles guided the council in drawing up its suggestions It urges that there should be a progressive development in pure geometry analytical geometry and analysis in each of the six stages into which the examinations of the Board are divided, that the six stages should give a homogeneous and comprehensive education in the main principles of the science and that the course of work for honours examinations should be such as to place the student in a position to undertake original investigations should he desire to do so It is a hopeful sign that teachers are able to lay before the Board of Education their views as to what it is reasonable and desirable to expect of candidates in examinations and we have no doubt the Board will give the suggestions the consideration they deserve Certain of the recommendations will be improved, no doubt by submission to revision, but the cooperation of teachers with outside authorities in the examination of students deserves every encouragement

According to an address delivered by Miss Hoskyns Abrahall in the Memorial Hall Manchester, and published by the Manchester and Salford Sanitary Association, the system of popular education now current needs radical amendment in order to prevent further physical degeneration on the part of the lower-class population of the country The system now in vogue is regarded as essentially non-hygienic, especially so far as infants and young children are concerned The maintenance of silence and order in infant schools (formerly regarded as a piece of mental discipline) is condemned, and in lieu of this it is urged that the pupils should be put to play in a large empty apartment with "a heap of sand in one corner and a tub of water in another" It may be pointed out that much the same results could be attained without expense by allowing the children to play in the old-fashioned way in the streets or lanes Nearly as drastic amendments are proposed in the curriculum for older pupils, while it is also urged that these should be kept at school until a considerably later age than is now the practice Neither is the education of teachers anything like perfect, one of the elements lacking being "skilled observation of children and skilful handling of them in accordance with what has been observed"

SOCIETIES AND ACADEMIES

London

Royal Society, November 1 1906—"On Intravascular Coagulation in Albinoes and Pigmented Animals and on the Behaviour of the Nucleo-proteids of Testes in Solution in the Production of Intravascular Coagulation" By G. P. **Mudge**. Communicated by Dr A D Waller F R S

(1) When albinoes are injected with a solution of nucleo-proteid derived from a pigmented animal, a certain number of them, about 9 per cent, absolutely fail to clot, while about 7 per cent give a *qualified clotting*, the remainder giving a typical intravascular coagulation of more or less extensive development

(2) When albinoes are similarly injected with a solution of nucleo-proteid, but derived from albinoes, no absolute failure of coagulation occurs, and it is very doubtful if any qualified ones do The great majority clot as distinctly as do pigmented individuals

(3) When pigmented rabbits are injected with solutions of nucleo-proteids, derived from albinoes or with those derived from pigmented individuals, no failures of coagulation occur

(4) The Himalayan rabbit in respect of its reaction to injected nucleo-proteids, behaves like the complete albino This rabbit, though resembling the Norway hare in its winter coat, in which condition Pickering failed to obtain intravascular coagulation, differs from it in having pink (unpigmented) instead of pigmented eyes and in never becoming periodically wholly pigmented It cannot, therefore be used as corroborative evidence of Pickering's conclusion with respect to the Norway hare

(5) Failures to coagulate, when they occur are due to inherent qualities of the individuals and not to weakening in the activity of the solutions used

(6) Albinoes require a larger mean dose per kilogram of body weight of injected nucleo-proteid to cause death by intravascular coagulation than do pigmented animals, the relative resisting powers of the pigmented and albino individuals being as 1 to 1 5 respectively

(7) Both albino and pigmented individuals are more resistant to nucleo-proteids obtained from individuals of their own race than they are to those obtained from the alternative source

(8) The activity of a solution of nucleo-proteid prepared from spermatic glands decreases (but not quite uniformly) as the maturity (weight) of the gland increases

(9) Solutions of nucleo proteids prepared from heavier (maturer) spermatic glands undergo a progressive loss of activity with increasing period of keeping *i e* from one to twenty days But solutions derived from lighter (immature) glands undergo a fluctuating variation in activity, falling off on the second day after preparation and rising again on the fifth to seventh, and thence exhibiting a progressive fall

January 24—"Note on the Application of Van der Waals's Equation to Solutions" By the Earl of **Berkeley** Communicated by Prof J Larmor, Sec R S

The author attempts to apply Van der Waals's equation of state to the results of direct measurements of osmotic pressure at 0° C Various modifications of this equation were tried without success but by the introduction of a third constant two equations were found that fit the experimental numbers

The equations are —

$$(A/v-p+a/v^2)(v-b)=RT \qquad (1)$$
$$(A/v+p-a/v^2)(v-b)=RT \qquad (2)$$

where p is the osmotic pressure, R and T the gas constant and the absolute temperature respectively, while the v of equation (1) is the volume of water which contains 1 gram molecule of solute, and the v of equation (2) is the volume of solution containing the gram molecule

It is pointed out that both equations give impossible values for the critical points, but on plotting the graph of equation (1) for the different substances, it is found that in each case the point at which $dp/dv=0$ and the osmotic pressure decreases with increase of concentration may be within the reach of experiment Decrease of osmotic pressure with increase of concentration implies physical instability and change of state, hence it is suggested that when $dp/dv=0$ the limit of supersaturation has been reached, and the solute must crystallise out

It is shown that a solution has two osmotic pressures the second osmotic pressure (which would only be manifested directly if one could find a semi-permeable membrane permeable to the *solute*) is connected with the freezing point of the solution in a manner similar to that which connects the crystallising point and the ordinary osmotic pressure

"On the Presence of Europium in Stars" By Joseph **Lunt**. Communicated by Sir David Gill, K C B F R S

Having obtained, from measures on the calcium line λ 4435 851 in the spectra of α Boötis and β Geminorum, radial-velocity values which were not in accord with those obtained from other stellar lines, the author suspected that the line near λ 4435 8 in the stars named was not a "pure" one The resulting radial velocity was such as would be given by a "disturbing" line very close to the calcium line and at about λ 4435 753 Reference to records of laboratory spectra showed him that Exner

and Hasselberg gave a strong line of europium at λ 4435·75. A search for other strong europium lines in the Arcturus spectrum revealed several abnormally strong stellar lines agreeing closely in position with the europium lines, and the author concludes that these cannot be explained without involving the rare element in question. Incidentally he reviews the evidence for the occurrence of the same element in the sun's chromosphere, and confirms Prof. Dyson's previous conclusions that europium is represented.

January 31.—"On the Discharge of Negative Electricity from Hot Calcium and from Lime." By Dr. Frank **Horton**. Communicated by Prof. J. J. Thomson, F.R.S.

This paper contains an account of some experiments in which the negative leak from hot calcium was compared with that from platinum and from lime under similar conditions. The negative leak from a platinum strip heated by an electric current was first investigated. This strip was then covered with metallic calcium by sublimation from an electrically-heated calcium wire situated in the discharge tube near to the kathode. The negative leak from the calcium-covered strip was determined at different temperatures. Some pure oxygen was then let into the apparatus, and the calcium on the kathode was oxidised to lime. The excess of oxygen was then removed and the negative leak again measured. Finally hydrogen was let into the apparatus, and the effect of this gas on the negative leak from lime was investigated.

The results obtained may be summarised as follows:—

(1) The negative leak from calcium is greater than from platinum at the same temperature.

(2) On oxidising the calcium on the kathode to lime there is a great increase in the negative leak. This is contrary to expectation, for we should expect the presence in the molecule of lime of the electronegative atom of oxygen to act as an attracting force tending to retain the escaping corpuscle, and that consequently the leak from lime would be less than from calcium under the same conditions.

(3) The negative leak from lime in hydrogen is much greater than that in air or helium.

February 28.—"The Occlusion of the Residual Gas by the Glass Walls of Vacuum Tubes." By A. A. Campbell **Swinton**. Communicated by Sir William Crookes, F.R.S.

On strongly heating portions of the glass walls of vacuum tubes that had been subjected to severe use in 1898, and had since been open to atmospheric pressure, they immediately became clouded, the effect being due to quantities of minute spherical bubbles of gas, which could be clearly seen with a microscope, and were on the average about 0·01 mm. in diameter. By dissolving away one surface of the glass with hydrofluoric acid until the bubbles just disappeared, and measuring the thickness before and after this process, it was ascertained that the bubbles were about 0·122 mm. from the inner surface of the glass. It would therefore appear that the particles of gas must have been shot into the glass to about this depth.

In a typical case the number of bubbles per square centimetre was found to be about 625,000, from which it was calculated that the total amount of gas at atmospheric pressure occluded in the particular tube was nearly 0·05 cm., apart from any further amount that may have escaped on the heating of the glass.

A number of pieces of the glass were next placed in a flat and air-tight tin chamber connected with a vacuum pump and a spectrum tube. This was exhausted until no electric discharge would pass through the spectrum tube, and was then hammered so as to powder the glass. There was an immediate fall of vacuum, and on examination with a spectroscope the gas that had been evolved was found to be mainly hydrogen. This process was repeated several times, the result in each case being to bring out more hydrogen. It would therefore appear that the gas occluded in vacuum tubes exhausted in the ordinary manner from atmosphere is almost entirely hydrogen, due, no doubt, to the electrolysis of water vapour.

Further experiments were tried with helium. A new tube was first exhausted until no discharge would pass, and then helium was admitted in small quantities from time to time with intervening sparking until 1 cubic centimetre at atmospheric pressure had been absorbed. The glass of this tube showed bubbles when heated, and on placing some of it in a vacuum chamber, as before described, and reducing it to powder, sufficient helium was evolved to show the helium spectrum clearly. Seeing that helium does not combine with anything at ordinary temperatures, and that this gas was extracted from the glass by mere mechanical powdering of the latter, it would appear that the occlusion is due to the mechanical driving of the gas into the glass, and not to any chemical combination.

Linnean Society, March 7.—Prof. W. A. Herdman, F.R.S., president, in the chair.—A series of specimens of *Nitella ornithopoda*, A. Braun, collected by the Rev. Canon Bullock Webster: H. and J. **Groves**. This rare species has only been found in a small district in the west of France, from Angoulême in the north to the south of Arcachon, and doubtfully in one locality in Portugal. The especial interest of the specimens exhibited, which were collected to the south of Arcachon in March and April, 1906, was that they represented gatherings of the plant from very different habitats, and showed great variations. The plants collected in shallow ditches were already in full fruit, while those from running water and from Lake Cazan were quite immature and so far sterile. Only a few specimens of this species have previously reached England, and the collection exhibited was probably by far the most extensive series of forms yet obtained.—The ornamentation of the frog tadpole, *Rana temporaria*, tracing the growth of golden spots which attain a maximum about the thirtieth day after the tadpole emerges from its gelatinous envelope: Miss N. F. **Layard**.—Decapoda captured during the 1900 cruise of H.M.S. *Research* in the Bay of Biscay, forming No. xi of the series of reports: S. W. **Kemp**. The majority of the specimens were larval adult Decapoda, being as a rule strong enough to swim out of an ordinary tow-net. A fine series of stages of *Acanthephyra purpurea*, A. M.-Edw., showed that, as Coutière predicted, this species hatches as a Zoæa, while the allied *A. debilis* leaves the egg in a "post-larval" condition with all its appendages formed. A curious feature of development was noted in that the rostrum and cornea, after considerable growth, undergo a sudden reduction, followed again by subsequent growth to the adult condition. The various stages, and those of a Caricyphus larva, were fully described and figured.—Colour changes in South African chamæleons, observed during the visit of the British Association to South Africa in 1905: Prof. L. B. **Poulton** and Dr. G. B. **Longstaff**.—The occurrence of *Spergularia atheniensis* and *Agrostis verticillata* in the Channel Islands: G. C. **Druce**.

Geological Society, March 13.—Dr. Aubrey Strahan, F.R.S., vice-president, in the chair.—A Silurian inlier in the eastern Mendips: Prof. S. H. **Reynolds**. The fragmental igneous rock is of two types:—(1) normal fine-grained tuff, from which in three localities more than thirty species of Silurian (probably Llandovery) fossils have been identified; the tuffs are seen at Sunnyhill to underlie the trap; (2) a coarse ashy conglomerate, the relation of which to the other rocks is obscure. Four possibilities as to the nature of this rock are discussed. It may be the basement-conglomerate of the Old Red Sandstone, an aqueous deposit belonging to the same igneous series as the associated trap and normal tuff, or an old river gravel deposited subsequent to the fossiliferous Silurian and prior to the Old Red, or it may represent the necks of the volcanoes from which the rocks were ejected. The last of these possibilities agrees best with the facts.—Changes of physical constants which take place in certain minerals and igneous rocks, on the passage from the crystalline to the glassy state, with a short note on eutectic mixtures: J. A. **Douglas**. The author describes the electrical apparatus employed. Powdered rock of known specific gravity is fused as often as required in a loop of platinum ribbon. The fused product is powdered, examined with the microscope, and then placed in a diffusion column. The diffusion column is sealed in a glass tube. Acid rocks were found to increase 6 per cent. to 10 per

cent in volume, intermediate rocks 5 per cent to 7 per cent, and basic rocks less than 6 per cent Of minerals tested, pargasite underwent the greatest expansion, albite gained 10 per cent, while in anorthite and leucite the increase was less than 4 per cent The melting points of the rocks and minerals experimented upon were found to range from 1260° C for rhyolite to 1070° C for Clee Hill dolerite The refractive indices of the glasses were determined in dense fluids An attempt was made to find experimentally the eutectic proportions of quartz and felspar A mixture of orthoclase and albite gave a melting point lower than those of either mineral taken separately

Royal Meteorological Society, March 20 —Dr H R Mill, president, in the chair —The exploration of the air Major B F S **Baden-Powell** Two classes of people are interested in the exploration of the atmosphere —(1) the meteorologists, who study it chiefly to find out about the weather, and (2) the inventors, who would utilise it as a highway of travel But these two are by no means rivals The attainment of their objects will be of mutual assistance to one another The aerial navigator will want to know all about the currents and the conditions of the air, while the meteorologist will derive the utmost benefit from the ability to visit any parts of the atmosphere There are three means now at the service of man by which he may ascend into these desirable regions, or may send up self recording instruments to probe the mysteries of the skies, viz balloons, kites, and flying machines The balloon, although at the time of its invention it was hailed with acclamation as promising the conquest of the air to man, yet it is now realised that this cumbrous and delicate apparatus is not capable of much practical application It is, nevertheless, useful (1) as an observatory for scientific investigation, (2) as a means of reconnaissance in war, and (3) as a most agreeable way of spending an hour or two in blissful peace and sublimity But recently great strides have been made in the improvement of the balloon in the way of providing it with engines and propellers so that it may be driven to any predetermined goal Twenty-five years ago the French Government made the first dirigible airship, and now it possesses one, if not more, that seems to be a really practical air vessel of war Count Zeppelin in Germany has also produced a machine which in point of size as well as in speed has beaten all records Going to the other extreme, we have small balloons now capable of attaining the greatest heights carrying self-recording instruments Such contrivances have recently ascended to the enormous altitude of 82 000 feet, or nearly sixteen miles above the surface of the earth Closely connected with this subject of *ballons sondes*, as the French call them, is that of meteorological kites These also have been much improved in recent years, and instruments lifted by kites retained by steel wires have actually ascended to a height of four miles Kites of a much larger dimension have also come into use during the last few years At Aldershot they have been regularly introduced into the service Men were first lifted by this means in 1895, in which year the lecturer made a number of ascents up to 100 feet high but improvements have gradually followed until now men have actually gone up to a height of 3000 feet, an elevation practically beyond the reach of rifle bullets and so high as to render the aëronaut almost invisible Major Baden-Powell, in conclusion, referred to a subject which, if it has not hitherto had any very practical results, yet promises to bring about perhaps more extraordinary changes in the life of man than have resulted from any other of the marvellous inventions of the nineteenth or twentieth centuries The flying machine has come, and it has come to stay During the last two or three years, not only have men been successfully raised off the ground, but have been able to sustain themselves in the air for half an hour at a time Very little more remains now to be done before we can say that man has veritably conquered the air

CAMBRIDGE

Philosophical Society, February 25 —Dr Hobson, president, in the chair —Some points in the anatomy of the peripheral nerves Dr B **Smith.** Several specimens were exhibited to show that the contour, size, and form of the nerve trunks of the body exhibited considerable variation, that these variations were associated with (1) the physical conditions of the tissue traversed by the nerve, (2) the displacements and strains to which the nerve trunk was subject, that the local enlargements which certain nerves exhibited were due histologically to (1) an accumulation of the intrinsic connective tissue in the nerve trunk, (2) the presence of numerous Pacinian corpuscles embedded in the nerve fibre bundles of the nerve trunk —An occipital vermian fossa and cerebellar vermian eminence Dr G F **Rogers.** A median occipital fossa 14 mm × 35 mm in the shape of a gutter was shown with a series of varieties ranging from a small triangular flattening at the base of the occipital crest through triangular fossae of increasing size up to the specimen noted above —The tendency to fusion shown by the suboccipital vertebræ Prof A **Macalister** A series of ankylosed cervical vertebræ in which there was exhibited a progressive coalescence of the several parts of the occiput and atlas, and of the axis and third cervical vertebra The stages ranged from a simple adhesion to a complete unification In one atlas there was a perfect neurocentral articulation between the pedicle and the axial odontoid process on one side —The range of variation in the navicular bone Dr M **Smith** An exhaustive investigation of the very large collection in the anatomy school results in the distinction of several well-defined varieties of the navicular bone —The histology of the early placenta in Semnopithecus Dr W L H **Duckworth** The anatomical department has received from Dr C Hose a specimen of the uterus of a *Macacus nemestrinus* in an early stage of pregnancy Microscopic examination of the placental area gives valuable and suggestive information as to the mode of connection of the maternal with the embryonic tissues in the earliest stages of placental formation showing in particular the fate of the uterine epithelial cells —A chemical test for "strength" in wheat-flour T B **Wood.** (See NATURE February 21, p 391)—The application of integral equations to the determination of expansions in series of oscillating functions H **Bateman.**

March 11 —Dr Hobson, president, in the chair —Reduction of carbon dioxide to formaldehyde (preliminary note) Dr **Fenton** Experiments were performed which demonstrated the direct reduction of carbon dioxide to formaldehyde in aqueous solution It was further shown that a similar reduction can be brought about indirectly, with formic acid as the intermediate stage —Dithioxanthoxalanil and its homologues S **Ruhemann** Thioacetanilide and its homologues react with ethyl oxalate in the presence of sodium ethoxide to yield coloured compounds, these, in composition, differ from the corresponding substances which the author previously obtained on using acetanilide and its homologues, by the replacement of two of their oxygen atoms by sulphur —Some observations on complex carbonates T B **Wood** and H O **Jones** The authors have investigated the solubility relations of potassium and copper carbonates, and determined the conditions under which the double salt $K_2CO_3CuCO_3$, crystallises out from these solutions —An optically active tetrahydroquinoline compound I **Buckney** Experiments have been made on a series of derivatives of tetrahydroquinoline containing a quinquevalent nitrogen atom, but at present the only compound that has been resolved is methyl allyl tetrahydroquinolinium *d*-brom-camphorsulphonate After repeated re crystallisation of the *d*-brom-camphorsulphonate from ethyl acetate and toluene, the less soluble portion had a molecular rotatory power of 195° in aqueous solution the value of $[M]_D$ for the basic ion consequently being −75° The more soluble portion gave a value for $[M]_D$ of 342° Hence the $[M]_D$ for the basic ion is +72° —A series of substituted bromanilines J R **Hill** These compounds were prepared in order to obtain from them two series of asymmetric nitrogen compounds by the addition of allyl and benzyl iodides Such series would only differ from those described by Miss M B Thomas and Mr H O Jones (Journ Chem Soc, 1906 p 280) by the presence of a bromine atom in the phenyl group In this way the change in the optical activity produced by increasing the weight of the phenyl group could be studied These

bromanilines were prepared by the bromination of the corresponding anilines, the series contains the bromophenyl and methyl groups with the ethyl, propyl, isopropyl, isobutyl, and isoamyl groups The isopropyl compound is a solid, the others are oils The bases were characterised by means of their picrates, and the quaternary compounds formed by addition of methyl iodide—Some new platinocyanides L A **Levy** In continuation of previous researches upon the fluorescence of platinocyanides (Trans Chem Soc, January, 1906), the author prepared uranyl, guanidine, and nitron platinocyanides, which were briefly described.—The resolution of salts of asymmetric nitrogen compounds and weak organic acids Miss A **Homer.** With a view to find out whether optically active nitrogen compounds could be used for the resolution of weak organic acids, that is, for those cases where a strong base is required, tartaric acid was treated with a solution of phenyl benzyl methyl isopropyl ammonium hydroxide prepared from the iodide, equimolecular quantities of acid and base being used A well-formed crystalline substance was obtained which on analysis proved to be the acid tartrate of the base used—A new coloured fluorescent hydrocarbon Miss A **Homer** A new hydrocarbon has been isolated from the products obtained by the action of aluminium chloride on naphthalene at 100° C, to which the formula $C_{24}H_{22}$ and the name tetramethyl erythrene have been assigned—Notes on the proportion of the sexes in dogs W **Heape.** The results show a remarkable similarity in the proportion of the sexes born by greyhounds, collies, and large dogs as a whole, while in terriers there is sufficient difference from the above to show that distinct racial variation occurs It is assumed from a variety of known facts that ova and spermatozoa are themselves sexual, and that the latest moment when the sex of the offspring can be determined is at the time of fertilisation—Preliminary note upon the presence of phosphorus in crystalline egg albumin Miss F G **Willcock** and W B **Hardy**—The natural units of mass length and time H C **Pocklington**—The variation of the absorption bands of a crystal in a magnetic field W M **Page.** An attempt is made to give a theoretical explanation of some observations made by M Jean Becquerel in the behaviour of the absorption bands of certain uniaxial crystals in a magnetic field

DUBLIN

Royal Irish Academy, February 25—Dr F A Tarleton, president, in the chair—The lower Palæozoic rocks of Pomeroy W G **Fearnsides,** Dr Gertrude L **Elles,** and B **Smith** The paper gives an account of the application of the modern zonal methods to a district made classic by Portlock so long ago as 1845 The beds developed are divided into the Desertcreat group, the Little River group and the Corrycroar group and are the equivalents of the Ashgillian, the Llandovery, and the Tarannon groups of Great Britain Of these the two lower groups are considered in detail, and are considerably subdivided The Desertcreat group rests unconformably upon the ancient hornblendic and granitic rocks to the north and is of a shelly or trilobite bearing type corresponding to the contemporaneous rocks of Girvan, its upper beds contain also a few graptolites and the interesting *Aeglina rediviva* The Little River group follows conformably, and like the rocks of Moffat is wholly graptolitic The rocks are much folded on the isoclinal plan, and the total thickness of the two groups mentioned can hardly exceed 600 feet Notes on the correlation with other areas and descriptions of certain interesting trilobites are appended The paper is illustrated by a map and sections

MECHANISM OF THE WORLD.

The World Machine. The First Phase, the Cosmic Mechanism By Carl Snyder Pp xvi+488 (London: Longmans, Green and Co, 1907) Price 9s. net.

IN this book the author purposes "to go back to the simplest beginnings of things—to the days when primitive man first learned to count, to measure, to time, and to weigh, and to mark out how his every step towards positive knowledge has been an advance toward mechanical conceptions of phenomena which must one day end in a mechanical conception of the whole." Two-thirds of the book are therefore devoted to a history of man's ideas about the construction of the universe, while the remaining pages give an account of the results of the investigations of the present day Among his predecessors the author mentions Pliny and Humboldt It would be unfair to blame him for not coming up to the high level of Humboldt, but it is unfortunate that he too often resembles Pliny in not having understood his sources properly, without resembling him in presenting his readers with a great mass of detail The narrative is very verbose, and does not clearly show how one idea or group of ideas has been developed from previous ones

The author has evidently not studied the original works of the heroes of science whose judge he has constituted himself, as he is anything but a trustworthy guide in the history of astronomy Among the historical works consulted he mentions Schiaparelli's memoir on the precursors of Copernicus, but he can hardly have read it carefully, since he repeats the old errors about Pythagoras and Philolaus having taught the heliocentric system Mr Snyder is not interested in those philosophers who did not know that the earth moves round the sun, and Plato and Aristotle are dealt with very severely Though he acknowledges that Plato knew something of geometry, he thinks that "the puerile phantasies with which his pages are strewn do not give us a very high idea of his powers of mind" Aristotle "cuts rather a sorry figure as a thinker," and the only philosopher of antiquity who finds favour in the author's sight is Demokritus, on account of his atomic theory

That the earth is a sphere the author imagines was undoubtedly known to the Egyptian priests, who communicated this discovery to Thales, and in several places it is hinted that the Egyptians and Babylonians knew a great deal more about the construction of the world than the Greeks ever did in after times This was the belief of Bailly (whom the author quotes among his authorities), but the discoveries of archæologists have long ago shown it to be devoid of the slightest foundation Among the Greeks, the author (or his source) fixes on a certain Bion, said to have been a disciple of Demokritus, but otherwise unknown, as the first to have worked out in detail the doctrine of the sphericity of the earth This is done solely on the authority of Diogenes Laertius, who says that Bion was the first to assert that there are countries where there is day for six months and night for six months That Parmenides and Pythagoras had announced the spherical form of the earth and divided it into five zones at least fifty years earlier is not mentioned

The various measures of the size of the earth are next dealt with, and it is stated that we do not know the exact value of a stadium It is, however, now quite certain that the stadium of Eratosthenes was equal to 157.5 metres, being the measure employed by the bematists or professional pacers, and that Posidonius used the same Their results for the circumference of the earth, 252,000 and 240,000 stadia, were therefore not very discordant, and the former was remarkably near to the truth Ptolemy, who gives 180,000 stadia, employed the official or Royal Egyptian stadium of 210 metres, so that he, in other words, simply adopted the value of Posidonius That Columbus thought India much nearer to Spain than it really is was therefore not caused by an error of Ptolemy in making the earth too small, but by his believing Asia to extend much further east than it does

If the author does scant justice to Eratosthenes in this matter, he certainly gives him far too much credit with regard to his idea of the distance of the sun We are told that, according to the "Placita Philosophorum," Eratosthenes gave this distance as 804 million stadia, a wonderful approximation to the truth So it would have been, but unfortunately the correct reading of the passage in question is 4,080,000 stadia, so that we need not trouble ourselves to find out how Eratosthenes came to know the distance of the sun so very accurately Neither was the knowledge of Posidonius on this matter very miraculous, for when he assumed the sun's distance to be 500 million stadia, it was a perfectly arbitrary assumption, in which he merely followed Archimedes In his "Arenarius," Archimedes had purposely made the circumference of the earth equal to three million stadia, in order to have large numbers to operate with, and the circumference of the solar orbit ten thousand times as great

No attempt is made to show how Aristarchus may have been led to suggest that the earth moves round the sun, but here, as everywhere else, the author fails to realise the state of science of past ages, and thinks that it "passes understanding" that Archimedes could accept the geocentric system The wonderful progress of mathematical astronomy, culminating in the work of Ptolemy, is quite ignored, and the picture of Greek astronomy presented by Mr Snyder is on the whole a very misleading one Passing to Copernicus, we find it stated that he discarded the system of epicycles, while the truth is that he had to employ them very largely, because he did not know the two first laws of Kepler The "third motion" of the earth assumed by Copernicus has

also been quite misunderstood As usual, the author is ready with his blame, and wonders that Lionardo da Vinci did not stand up for Copernicus. But as he died twenty-four years before the book of Copernicus came out, he may be held excused The same is the case with Kepler, who could not very well make use of Galileo's little book on mechanics written in 1594, since it was not printed until four years after Kepler's death Of Galileo we learn that he showed that the speed of a falling body increases with the square of the time (p 256) Had he really done so he would have deserved to be enrolled among the delinquents castigated by the author So would Newton, if he really had proved that the mass of a body may be calculated if we know the period and distance from the central body, or that gravity is less at the poles than at the equator (p. 261)

The author has succeeded better in the last hundred pages, which deal with stellar astronomy, the last chapter discussing the question of the probable "end of the machine" His own opinion is that all bodies will finally be congregated into a single mass, but he also sets forth the view of Arrhenius, that the matter of the universe follows a continual round of alternating aggression and dispersion

J L E D

THE MATHEMATICAL ASPECT OF SPECTROSCOPY

Vorlesungen über teoretische Spektroskopie By Prof A Garbasso Pp viii+256, illustrated (Leipzig Johann Ambrosius Barth, 1906) Price 7 marks

IN the printed report of the lecture delivered before the Royal Institution on March 30, 1906, on "Recent Progress in Magneto-optics," Prof Zeeman concludes with the following remarks —

"Maxwell has said, 'an intelligent student armed with the calculus and the spectroscope can hardly fail to discover some important fact about the interior structure of a molecule' I think this statement remains as true now as it was thirty-two years ago

"There can be no doubt, I think, that spectrum analysis, and especially the magnetisation of the spectral lines, will give us a clue to the inner structure of the atom

"I hope that I have succeeded in imparting to you this my conviction"

Now Prof Garbasso's book seems to us exactly to cover the ground contemplated by Prof Zeeman when he wrote these concluding remarks It is, in fact, a well-planned attempt to build up an electrodynamical theory of the phenomena of spectroscopy, using no more difficult mathematics than the ordinary calculus of mathematical physics

In spite of the fact that the word "electrodynamical" has gone out of fashion, and that it is more proper nowadays to say "electromagnetic," the old word is here retained as representing more correctly the spirit of the present book If the equations of the electromagnetic field are written down and the quantities in them are defined in the phraseology of the physicist, the study of these equations is rightly described as electromagnetism. By representing the quantities in question as generalised position coordinates and the corresponding generalised momenta in Lagrange's equations, the study is brought under the heading of dynamics. Inasmuch, however, as there is no hard and fast line of demarcation between the two methods, and it is a matter of convenience which interpretation is used, the name "electrodynamical" well describes the methods of a book in which both aspects are considered.

The book is divided into twenty lectures, and is based on a course delivered at the University of Genoa Of these, the first four form the first section of the book, and consist chiefly of introductory matter, namely, a summary of the principal phenomena of spectroscopy, a description of certain electromagnetic and electro-optical models and their application to the explanation of optical resonance, and a mathematical lecture dealing with the well-known theory of small oscillations, transformations of line, volume and surface integrals, and similar "auxiliary propositions"

The second section deals with Cauchy's theory of dispersion, Helmholtz's theory of anomalous dispersion, and a lecture on mechanical models of compound molecules, based on work by Dr Filippini, of Genoa, who uses various forms of compound pendulums for the purpose of representing the various degrees of freedom of the assumed molecules

The subject proper of the book, namely, the building up of mathematico-physical theories, commences with the eighth lecture, and occupies the two remaining sections of the book These two sections afford typical instances of what has been, and is likely to be, the most interesting and prolific field of research in dealing with complex physical phenomena To "explain" such a phenomenon we formulate some system, dynamical or otherwise, the equations of motion of which are capable of being integrated, and the integrals of which when interpreted represent effects similar to those observed The assumed system then constitutes a model of the given phenomenon Dr Garbasso has endeavoured to confine his treatise to the discussion of phenomena that are capable of being studied by means of models, adding that

"A theoretical exposition which does not take account of the properties or of the possibility of its model is for physicists no theory but only a chaos ('ein Unding')"

The models made use of in the third section are all electrical oscillators, each represented diagrammatically by two or more conducting spheres connected by wires For one-dimensional oscillations, simple oscillators each represented by two spheres are chosen; for three dimensions the author mainly employs compound oscillators having their conductors parallel to the three coordinate axes. These are, of course, simplifying hypotheses, but, as the author points out, for example on pp 124, 149, the character

the determinant is of a very high order in all but the simplest possible cases, and certainly the purpose of the investigation, that of judging the unknown from the known, is best served by keeping the mathematics as simple as possible. Even when this is done the author obtains theoretical confirmation of the known results regarding the spectra of metallic haloid salts (Lecture 14, § 1), Lockyer's long and short lines, and observations on the dissociation of the elements in the solar protuberances (Lecture 1, § 7, and Lecture xiv, § 6), Kayser and Runge's series of spectral lines, and the phenomena of surface colours ("Schillerfarben"), under which heading the colours of butterfly scales are discussed at some length, this application being illustrated by an excellent photograph of the scales of one of the "blues," in which the dimensions of the pigment granules are equal to the wave-length of blue light

This section deals, then, with the electromagnetic theory of spectroscopy of which Lecture 14 forms a general summary In the fourth and last section many of the same results are established in a different way, by what the author describes as the electrostatic theory This theory is based on the study of moving charges, and regards the molecule built up of electrified moving particles It is, in fact, the electron theory, and the first lecture contains a proof that in the cases considered the electromagnetic forces are negligible compared with the electrostatic ones The succeeding chapters deal with Dr Stoney's theory of double lines, J J Thomson's models of atoms, and conditions of stability with special reference to the periodic law The last lecture (Lecture 20) is a summary of the electrostatic theory, and contains explanations of the phenomena referred to above, based on this theory

In summing up, Dr Garbasso expresses the opinion that the electromagnetic and the electrostatic theories, and in some cases even mechanical models, are equally competent to account for observed phenomena The electrostatic method he considers to be the most complete, but the electromagnetic method possesses considerable advantages for teaching purposes, it possesses a peculiar heuristic value, and opens up the possibility of reproducing the electrical oscillations artificially

The book makes no claims to being a text-book, or in any way a complete account of all that might be said on the subject It contains, no doubt, many proofs that are open to criticism, but experience has shown that objections are very generally raised years after a book has been written, and very often on work which has been accepted unchallenged by a large number of readers The main points we have now to consider are whether the author has stated his case well and carefully, whether the book is calculated materially to help us in unravelling the many curious puzzles revealed by the spectroscope, and whether the methods adopted are the best suited to the objects in view, and on each of these points we pronounce judgment in the affirmative

G. H B

ORIGIN OF THE ENGLISH NATION.

The Origin of the English Nation By H Munro Chadwick Pp viii+352 (Cambridge The University Press, 1907) Price 7s 6d net.

THE title of this work really conveys a more accurate suggestion of its scope than the first sentence of the preface, which describes it as "an account of the early history of the English nation" There was certainly room for such a work, in which all the available evidence should be carefully considered, and Mr Chadwick has done this with the greatest minuteness In fact, his book suffers to some extent from over-minute discussion of questions which have at best a very faint bearing upon the main subject of his inquiry This is especially the case with the later chapters in the volume, such as that on the "Cult of Nerthus"

Another general criticism which might be made is that Mr Chadwick is rather too much given to the common, but very unsatisfactory, process of drawing a strong conclusion from a series of very weak premises, Unfortunately, much of the evidence relating to the Germanic conquerors of England during the time before the invasion is so fragmentary and contradictory that hypotheses can hardly be avoided It is therefore the more necessary that they should be used as sparingly as possible, otherwise they are apt to obscure the recorded facts In particular, it is of little service in the end to set modern supposition against ancient assertion, the former is at least as likely to be wrong as the latter, even when it appears to reconcile contradictions The author, for example, seeks to cast doubt upon the express statement of Bede that the invaders came from three nations, the Saxons, Angles, and Jutes On various grounds, such as similarity of language and customs, he comes to the conclusion that there is not sufficient evidence for separating the Saxons from the Angles, and that the invaders "belonged not to three but to two distinct nationalities"

That the distinction cannot be clearly perceived now does not prove very much, it may have been clear enough to themselves and to Bede It may even to some extent have become obscured through the migration to a new country, just as national differences soon tend to disappear in modern colonies Or the difficulties raised by Mr Chadwick may simply lie in the meaning to be attached to "nation" or "people" In Scandinavia of the tenth century we find four very distinct peoples who did not differ from each other in any essential respect It is no argument against the reality of the Saxon element that *Englisc* and *Angelcynn* became the usual designation of the language and the people Where no great difference was felt, the convenience of a common name would soon be obvious The use of national names is not stable enough to be valid evidence in doubtful cases The lowland inhabitants of Scotland in the fifteenth century called themselves Scots and their language English, and Snorri Sturluson evidently saw nothing contradictory in

making Norwegian kings speak "the Danish tongue" These instances show how readily the name of the Angles might efface that of the Saxons even at an early date

While such objections may be made to some of Mr Chadwick's arguments, the method he has followed in tracing the origins of the English people is a sound one He begins with what can be learned of the invading nations immediately after their settlement in Britain, and from this works back as far as possible into their previous history A necessary result of the method, however, is that as the inquiry advances the evidence becomes more scanty, and the use of conjecture more and more obvious For this there is no help, but it seems a little disproportionate to give only ninety pages to the English period and two hundred and fifty to the Continental, of which so little is known These ninety pages contain four chapters, of which the first gives a survey of England in the sixth century, showing the extent of the conquest at that date The West Saxon invasion, and that of Kent, are specially discussed in the following chapters, and the fourth is occupied with the question of the three nations referred to above It includes some useful tables of early linguistic variations, and remarks on these, together with an account of the difference between Wessex and Kent in respect of the various classes of the community and their wergelds

The very hypothetical character of Mr Chadwick's inquiry does not do full justice to the great mass of interesting matter which he has brought together A very wide range of reading and research underlies every chapter of it, and each point has evidently been the subject of much study and consideration Many of his views are highly suggestive, and may yet lead to more certain results In the meantime, the evidence produced does not seem sufficient to convict Bede of any essential error, or to modify in any important way the usual views on the subject

W. A Craigie

THE RAINFALL OF NORTH GERMANY

Die Niederschläge in den norddeutschen Stromgebieten By Prof G Hellmann In three volumes Vol i, pp vi+386+140, vol ii, pp viii+722, vol iii, pp viii+872 (Berlin Dietrich Reimer, 1906) Price 60 marks

DR HELLMANN'S three volumes contain a wealth of information relating to the rainfall and allied phenomena in the North German river basins The principal observations are elaborately reduced, and in many aspects very fully discussed The significance of this rainfall in its wider relation as part of the world weather, and, as such, its probable correlation with solar changes, are investigated with the advantage of well-marshalled data

The area specifically dealt with in the volume is extensive, consisting practically of the great plain which extends without interruption from the chain of mountain ranges in south Germany to the North Sea and the Baltic The direction of the river flow and the precipitation of the country are very largely determined by this chain of mountains, which is part of the great water-shed of Europe The conditions of the rainfall problem over such an area would seem to be fairly simple, and capable of being dealt with in general terms The local conditions, however, as is usual, exercise a considerable influence, the "actual" varying widely from any "mean"

The three volumes may be taken as a summary of the meteorological work of many years in the department of rainfall measurement within the district named Its fulness and painstaking completeness is such as is expected from the efficient State-supported meteorological organisation of Germany Much of the data is from the numerous and evenly distributed stations, daily returns from which are made immediate use of for short-date forecasting

The first volume is general, describing and discussing the data and results This volume is divided into five sections, of which the first, in dealing generally with the observation material and the manner in which it has been obtained, discusses the distribution of stations and the quality of the observations themselves The recognition of the influence on these of the type and position of the gauges used is of value Such considerations affect the credentials of the older observations, a knowledge of the standing of which allows the full length of the record to be used safely or to be rejected where untrustworthy A long meteorological record is sometimes, like the curate's egg, merely good in parts The ease of approximate rainfall measurement conduced to its early commencement, and very old records exist Observations made at Breslau (1717–1727) gave an annual mean of 576 mm, which does not differ greatly from the modern value of 567 mm A valuable bibliography of the history of rainfall measurement concludes this first part

The amounts of rain and their reduction and intercomparison are next dealt with The influence and value of smoothing curves by taking means is illustrated both by actual curves and by tables Means for several stations, for periods varying from five to forty-five years, together with the "greatest differences" in each set of means, are obtained and compared The standing of short-period means and the necessity of taking a long period to obtain a normal value become clear A valuable table of monthly seasonal and annual means, both actual and percentage of mean year, is given in the text for nearly 100 stations The distribution of rainfall in the year, from ten- and twenty-year means, is discussed and illustrated by curves for Konigsberg and Stettin Abnormal rains and thunderstorms are considered at some length, while material for further discussion is given in tables of great detail

The reduction of the data is further extended in the next section of the volume to the problem of the determination of the expectancy of greatest rainfall and the probability of the number of rainy days of definite intensity Various mean curves are used depending on periods of observation of from nineteen to forty-three years Snowfalls are dealt with in re-

lation to snowy days, and their number and distribution throughout the year are illustrated, as usual, with compact tables of mean values for a large number of stations Mean first and last snowfalls, here effectively tabulated, are important factors in the estimation of the climate of any place

To this point the work deals with general conditions and mean values drawn from the long and trustworthy records discussed. In the sequel, that most obvious fact about rainfall, its variability, receives attention. The outstanding and apparently abnormal features are discussed, and a very complete list of dry and wet seasons from 1851–1900 is here available for critical investigation The attempt to correlate these changes with larger variables, cyclic or otherwise, is a most important work The rainfall, considered in relation to the well-known sunspot period, seems to indicate that periods of maximum precipitation are bound up with maxima of sun's spotted area The author, however, is not able to consider these directly related as cause and effect, while he suggests that Sir Norman Lockyer's views as to the importance of prominences and allied phenomena may be nearer the true relation The reader is specially referred to Sir Norman Lockyer's "Report on Simultaneous Solar and Terrestrial Changes" as best setting forth the general relationship between these two classes of phenomena

The second and third volumes contain tables of data arranged under observing stations in the river basins

The work is a monument to the value of scientific organisation and industry, and illustrates the high worth of collecting long, trustworthy, and continuous meteorological records

OUR BOOK SHELF

The Zoological Record Vol xlii Being Records of Zoological Literature relating chiefly to the Year 1905. Edited by D Sharp (London Zoological Society, 1906)

WITH this volume ends, at any rate for the present the series of this invaluable work with which we have been so long familiar, for next year the amalgamation with the zoological section of the International Catalogue of Scientific Literature is to commence One effect of this change will be to make a radical alteration in the abbreviations employed for the titles of zoological serials, a change which, from the point of view of the working naturalist, is distinctly to be deplored Whether the new arrangement will give that relief to the recorders to which the editor alludes so confidently in the preface remains to be seen

In the main, the present volume follows the same lines as its predecessors, and displays the usual high level of excellence By a rigorous system of cutting down, it has, however, been found practicable to make a considerable reduction in the number of papers in the general section

Owing to the retirement of one old and experienced member of the staff, it has been necessary that a new recorder should undertake the sections dealing with reptiles, (inclusive of amphibians) and fishes, and it is unfortunate that the editor has not apparently realised that this new member of his team required more attention than the old stagers To allude to a tithe of the serious and misleading errors in these two sections would be impossible, and we can only indicate a few of the most glaring Geography seems a very weak point with this recorder In the fish section for instance, the Rio Negro is placed in Africa, while the eastern seas of the Russian Empire are included in Europe Arabia in the reptile section, comes under the heading of Africa, while in the fish section Muscat and Oman are placed in Asia "Ophidia" too, is so placed and printed on p 27 of the reptile record as to convey the idea that it stands for a country It should also have been explained that "Riu-kiu" is the Chinese equivalent of "Liu-kiu" or "Loo-choo"

As to misprints it might almost be said that their name is legion, but as examples it must suffice to notice *Epiorates* for *Epicrates*, *gandrvi* for *gaudryi*, *Hoodwell* for *Hordwell*, *Malaclemmys* for *Malacoclemmys*, and *Tyrranosaurus* (repeated in the list of new genera) for *Tyranosaurus* In the case of a large number of new species of reptiles the localities are omitted while many papers quoted in the title-list are not referred to in the subject index None of the genera included in the Percidæ really belongs to that group

The other recorders seem for the most part, to have done their work well, although it would have looked better if the somewhat long list of corrigenda to the mammal record had not been required

R L

The Principles of Horticulture A Series of Practical Scientific Lessons By Wilfred Mark Webb Pp 136 (London Blackie and Son, Ltd, 1907) Price 2s

THE experience of the author as a former teacher and demonstrator in the Essex County Council School of Horticulture has served him in good stead He puts a plant into the hands of the pupil shows him how to study it indicates to him what there is to be learnt from it both as to external form and internal function and having thus rendered help in the preliminary stages leaves the pupil to make himself master of further details by his own exertions

We rather doubt the advantage of beginning microscopical work at so early a stage, and should prefer to defer the investigation of the minute anatomy of a plant until the pupil has become familiarised with the facts of morphology The search for sieve-plates and companion cells might well be left until the pupil has familiarised himself with morphology and classification Stress is very properly laid on the importance of drawing, as every student soon finds the great help of sketches of even the roughest kind, provided that they show what the draughtsman saw or intended to see Accuracy of detail rather than artistic effect is what should be aimed at, and it is a matter of surprise to see the excellent representations which pupils make after very little practice The illustrations in the present book afford a good example of our meaning, they show what they are intended to show, though they are not pictures A list of the natural families, arranged according to the system of Engler, is given For the purposes of the beginner it would, we think, have been better to have picked out some dozen or score of the most important orders, and to have omitted a mass of detail not required by the average student and not full enough for those who desire more complete information

A section is devoted to the insects which prey upon plants, and to the measures to be taken for the destruction of these pests, as well as of fungi That the book is up to date may be gathered by the references to Mendelism and De Vries

A copious index is given, as well as hints as to the way in which examination questions should be answered

A little more information as to the "reason why" of digging, watering, striking cuttings, and other garden operations would have increased the value of the book, which nevertheless is one which can confidently be recommended to the attention of all those interested in gardening

Dr Schlich's Manual of Forestry Vol iv Forest Production By W R Fisher Being an English adaptation of "Der Forstschutz," by Dr Richard Hess Second edition Pp xxiii+712 (London Bradbury, Agnew and Co, Ltd)

This volume is the second edition of Prof Fisher's "Forest Protection," and is uniform with the third edition of vols i, ii, and iii of Dr Schlich's "Manual of Forestry" The book is an English adaptation of Dr Hess's "Forstschutz," that is, it is not a mere translation, as the author has exercised discretion in his selection of material in order to make the book more adapted to the use of British and Indian foresters New illustrations have also been added which are not in the German edition The subject of forest protection is of immense importance, and covers a wide field of knowledge, practically including every branch of scientific sylviculture The author has arranged and presented the various protective measures to be adopted against inimical agencies both in the organic and inorganic worlds in a very clear and interesting manner The volume also contains a useful index at the end Prof Fisher has done valuable work by rendering available to student and forester a vast store of information which has hitherto been accessible only to a few The book is one which we can warmly recommend to all those who have forests or trees under their charge

The Essentials of Histology, Descriptive and Practical By Prof E A Schäfer, F R S Seventh edition Pp xi+507 (London Longmans Green and Co, 1907) Price 10s 6d net

The fact that this volume has reached its seventh edition shows conclusively that it supplies a want The features of the present edition are the introduction of colouring in the illustrations and a considerable increase in the part devoted to the nervous system In this portion practically a new set of illustrations appears, which can only be described as admirably calculated to indicate the salient points which the elementary student must be familiar with Either for the purely scientific or for the medical student this book will continue to be of the highest value

Actualités scientifiques By Max de Nansouty Pp 361 (Paris Schleicher Frères, 1906) Price 3 50 francs

The general character of this annual publication was described in noticing the issue for 1905 in Nature of November 23, 1905 (vol lxxiii, p 76) The short essays on scientific subjects of current interest range over most branches of science and should be useful as reading exercises in French classes in schools where the pupils also learn something of science

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. No notice is taken of anonymous communications]

A Hydraulic Analogy of Radiating Bodies for Illustrating the Luminosity of the Welsbach Mantle.

The device about to be described enables us to illustrate to a class the behaviour of different types of radiating bodies when introduced into a flame, and will be found especially useful in explaining the remarkable luminosity of the incandescent mantles used in modern gas-lighting. It is, of course, not intended to explain the mechanics of radiation, but merely to enable us to describe certain phenomena in terms of easily grasped notions

Students are told that the more powerfully a body absorbs the more powerfully will it emit when heated, this relation holding for every individual wave-length Black bodies, then, give out the most light when heated The fact that a white block of lime is far more luminous than a carbon rod when heated in the oxyhydrogen flame is not usually cited in support of this law, while the fact that the most luminous body of all, the Welsbach mantle is also quite white, is equally unsatisfactory as an illustration, for white bodies are in reality transparent, that is, they are made up of masses of small transparent particles, and transparent bodies ought not to emit at all It is, of course, necessary to define just what we mean by transparency in this case, and it may be well to consider first a somewhat analogous case The absorption which is accompanied by high emissivity is true absorption, and not selective reflection, which is sometimes confused with absorption A highly reflecting polished metal surface is a poor radiator, but by properly constructing its surface we may give it the power to absorb and emit A bundle of polished steel needles with their points all turned towards the source of light reflects scarcely any light at all, the rays undergoing multiple reflections between the conical ends of the needles Such a bundle of needles should emit much more powerfully than a polished steel surface, and it is easy to see just why it should do so Each needle seen end on, sends not only emitted light to the eye, but reflects rays coming from its neighbours The surface formed by the points of the needles can be regarded as an absorbing surface, which absorbs in virtue of its structure, it is analogous to the hollow "black bodies" with which we are now familiar. The point which I wish to emphasise is that such a surface which absorbs not at all in virtue of its molecular nature, is also a powerful radiator, the mechanism by which its radiating power has been increased being as indicated above

Suppose, now, we take a perfectly transparent body, which, like a perfect reflector, has no emitting power A bead of microcosmic salt (sodium pyro-phosphate) heated in a blast lamp is a good example Though the platinum wire which supports it glows with vivid incandescence, the bead remains perfectly dark A glass bead, however, emits a good deal of light, doubtless from the fact that its transparency is much less at high temperatures, a very common behaviour of transparent substances. The microcosmic salt on cooling becomes traversed by hundreds of cleavage planes, which give it a milky appearance On re-heating it it emits light strongly, until it finally fuses into a transparent drop, when it instantly becomes dark again The reason for this behaviour is not quite so apparent as in the case of the needles In fact, I am not quite sure that I understand it at all. Quartz behaves in the same way A drop of clear fused quartz, heated in the blast emits little or no light, but if it contains spots made up of an emulsion of quartz and air, these spots emit strongly In other words, an opacity resulting from a pulverisation of the transparent medium seems to be accompanied with a strong emitting power Apparently we cannot apply the same reasoning as in the case of the needles, and it looks rather as if the radiation was largely a surface effect If this is so, it is obvious that an

increase of the surface, by enclosures of air, will increase the radiating power. It is my intention to make some measurements of the intensity of the light radiated from the ends of long and short cylinders of red-hot glass

The hydraulic analogy of radiating bodies which we will now consider occurred to me during a lecture on radiation, and proved quite useful in explaining the different behaviour of various types of radiators

The radiator is represented by a tall hollow cylinder, open at the top and closed at the bottom, provided with a number of outflow pipes of different sizes as shown in Fig 1. Water flows into the cylinder at a certain definite rate from a horizontal pipe or flume, the height of which above the base of the cylinder (T_1) represents the temperature of the flame Obviously the level of the water in the cylinder will rise until the rate at which the water flows out exactly equals the rate at which it flows in This height (T_1) is the temperature which the radiator acquires in the flame The jets of water which issue from the tubes represent radiation of different wave-lengths, the small jets representing the short waves

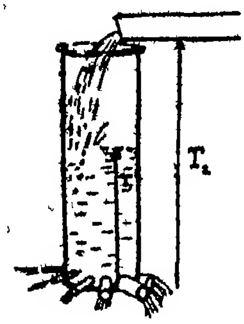

FIG. 1

We will first suppose our hydraulic radiator to represent a black body, say a lump of carbon In this case all the pipes at the bottom are wide open and we have the maximum outflow of all wave-lengths for any given temperature, *i e* for any given height of the fluid within the cylinder If we take the cylinder empty and plunge it into water, jets will squirt into it through the pipes that is, it is a perfect absorber for all wave-lengths With all the pipes open, however, the level of the water within the cylinder will not rise to any great height, owing to the limited rate at which water flows in from the horizontal pipe This means that the lump of carbon in the flame does not rise to a very high temperature because it radiates energy at a high rate At the low temperature there is comparatively little visible light in the radiation, for the shorter waves only appear in quantity at high temperatures We can imitate this condition in our hydraulic model if we choose by putting valves on the inside of the tubes, those on the small tubes opening only at high pressures

To make our model imitate the bead of microcosmic salt we plug up all the pipes The cylinder now represents a transparent body If immersed in water it absorbs nothing through the pipes, and no matter how high the level of the water rises in it there is no emission of fluid, in other words, no radiation The body rises in temperature until the temperature is equal to that of the flame, but there is no radiation Take next the case of the lime in the oxyhydrogen flame It is a partially transparent substance, and we can imitate it by plugging the tubes with glass beads or cotton Owing to the lesser rate at which the water now flows out through the tubes the level rises much higher than when the tubes are all open, and owing to the greater pressure (temperature) we have liquid jets through the small tubes (short wave-length radiation) The inferiority in the emissivity is more than made up for by the higher temperature which the body can acquire. We are now ready for the Welsbach mantle

It has been conclusively shown by Rubens that the peculiar brilliancy of the thorium mantles, caused by a small trace of cerium, is due to the fact that the cerium makes the thorium selectively absorbing for the short waves at high temperatures If we wave a Bunsen flame over a mantle in a brilliantly lighted room, it will be seen to turn yellow at a temperature a little below a red heat In other words, it becomes a strong absorber for the short waves It is, however, transparent for the long waves, consequently it does not emit energy at anything like the rate at which a black body does, and in consequence can rise to a high temperature in the flame, exactly as a pure thorium mantle Its band of absorption in the blue region enables it to pour out visible radiations nearly as powerfully as those which a black body at the same temperature would emit, hence its enormous brilliancy Our hydraulic model, with its tubes all plugged with cotton, represents the mantle of pure thoria, while to transform it into the Welsbach mantle we have only to pull out the porous plugs from some of the smaller tubes. In this condition, owing to the impeded flow in the large tubes, the water will rise in the cylinder to a great height, and we get very powerful jets from the small tubes which we have opened, much more powerful than in either of the previous cases considered Of course, with all the tubes open we could get equally intense small jets if we poured the water in at the top at a sufficient rate There is a limit to this rate, however, for it is obvious that the rate at which the water is poured in at the top corresponds to the rate at which the flame can pour energy into the radiating body, a circumstance which depends on the conductivity of the body for heat and other things

It is not necessary to make the hydraulic apparatus, of course, for its action is so easily understood that a diagram answers every purpose Its utility lies in the fact that it fixes in the mind of the student the behaviour of different types of radiators when plunged into a flame

It could be made, perhaps, to illustrate the displacement of the point of maximum energy in the spectrum which accompanies a rise in temperature, but it is doubtful whether any such complications would prove beneficial It seems best, on the whole not to try to illustrate too much with it, as its relation to a radiating body is at best rather far-fetched R W WOOD

Johns Hopkins University, Baltimore

Retardation of Electroscopic Leak by means of recognised Radio active Substances

IN a communication made to the Royal Society on April 5 1906, and subsequently published in the "Archives of the Middlesex Hospital," vol vii I described certain experiments which I regarded as showing that substances exist which retard the leak of an earthed metal electroscope I further asserted that an aluminium plate which had been kept in proximity to, but not in contact with, uranium, thoria or pitchblende also retards the electroscopic leak This retardation does not necessarily occur immediately after introduction of the modified aluminium plate into the electroscope for after proximity to thoria there is a period, lasting three or four days during which the leak is accelerated and after proximity to radium I failed to find any evidence of retardation whatever My results were received with scepticism, except by Sir William Ramsay, who had independently observed the same phenomenon in his laboratory It is impossible to occupy your space with details but it may be stated that gold-leaf electroscopes made of ⅛ inch lead were used, that the earthing of electroscopes and aluminium was complete that effects of induction and alteration of capacity of the electroscope were eliminated, and that the general conditions were kept as constant as possible

Since reading the paper I have repeated the experiments in the most stringent way of which I am capable in a pathological laboratory, and have obtained identical results Further, using the same apparatus, I have exposed the aluminium plates to X-rays for a period of three hours, and have found a complete absence of any change in the rate of leak, whether in the direction of retardation or of acceleration Full details of these experiments will be published in the forthcoming number of the Archives of the Middlesex Hospital Below I give the salient points of an experiment which was carried on continuously from August 10 to December 24, with the exception of intervals August 27 to September 11, and September 19–30, during both of which the electroscopes were left undisturbed The values given represent percentages of the mean leak of the electroscope during twenty-four hours under normal conditions corrected by the leak of the control electroscope on the day for which the observation is given

Lowest corrected percentage during period August 10 to

October 12 (standardisation period) = 84.8 On nine out of thirty five observations during this period the corrected percentage was below 90

Lowest corrected percentage during two blank experiments, each lasting twelve days = 89.1 On one out of twenty observations during these two periods of blank experiment the corrected percentage leak was below 90

Lowest corrected percentage during period November 7–17 after two days proximity of the aluminium plate to pitchblende = 81.9 On ten out of eleven observations during this first period of true experiment the corrected percentage was below 90

Lowest corrected percentage during the period November 21 to December 24, after a two days' re-approximation to pitchblende = 79.5 On thirty-one out of thirty-five observations during this second period of true experiment the corrected percentage leak was below 90

Atmospheric See Saw Phenomenon and the Occurrence of Typhoon Storms

IN January last there was a very noteworthy barometric change agreeing in a high degree with the results of those synodal pressure periods which have been affirmed for European latitudes by the statistical investigations of two German meteorologists, Captain K Seemann and Dr G Meyer These results require high pressure at the time of the first quarter and low pressure at the time of the full moon, especially in the months from September to January Last January was also in a synodal respect marked by its elliptical character, so it agrees accurately with those requirements, the first date (January 21) nearly coinciding with a record of high pressure in northern, central, and eastern Europe, and the latter date (January 29) with a decidedly low pressure The conditions on the following first quarter (February 20) were completely reversed, for on this date there was a remarkable record of low pressure in the above parts of the earth atmosphere

This direct reversal of the pressure conditions of January was sufficient to excite the suspicion of a kind of see-saw phenomenon This suspicion has been confirmed by a synoptic investigation of the barometric conditions over the whole earth, so far as information is at present available The isobar of 760 mm surrounded on February 20 the greater parts of Europe the North Atlantic, and North America The whole area contains more than 50,000 000 square km, nearly one tenth of the whole surface of the earth, but it soon became possible to prove that an area of very high pressure also existed on February 20 This area had its centre over Transbaikalia The weather report of St Petersburg records on that day barometric observations from Chita of 789.8 mm from Nerchinsk of 765.0 mm and from Irkutsk of 783.4 mm In Chita and Nerchinsk the barometer was ascending from February 19 to February 20 It is possible, too that those tabulated barometric readings were too low In the same reports the maps of January 22–23 show areas of more than 800 mm but in the tables the readings of all stations, including the stations situated in those areas, are below 800 mm

This record day of high pressure, examined in the same manner shows a much more widely spread area of pressure over 760 mm than the area in which the readings of February 20 were under 760 mm The high-pressure area of January 23 seems to contain nearly the whole of Europe, the greater parts of Asia and America, the Northern Atlantic, the Chinese and Indian Seas Mostly below 760 mm apparently were the continents of Australia and Africa and south western Asia The whole area of high pressure contained about 157 000 000 square km nearly one-third of the surface of the earth

To the east of the Japanese islands from Formosa to Yeso, there were some depressions below 760 mm and 763 mm which had shown on the previous days more or less a typhoon character Zikawei recorded on January 23 an area below 754 mm between 22° and 30° N lat and east of 140° E long The very lowest barometric reading of the same day is recorded—so far as there is information—in South Argentina, C Virgenes in N E Tierra del Fuego showing a pressure below 750 mm

The atmospheric conditions prevailing on January 23 over the N W Pacific point to a possible connection of the pan-atmospheric see-saw phenomenon with typhoon storms. Indeed, the extreme depressions of these storms seem able to exercise an influence on the common atmospheric situation Further, the most frequented typhoon areas nearly coincide geographically with the two areas of contrary see-saw, as these areas are ascertained by my method of qualitative analysis of some barometric diagrams The two areas are the Indo-Australian and the Central American regions

I feel bound to publish these preliminary notes first in an English journal, because my researches in the main were made possible by the materials which the Meteorological Office in London liberally placed at my disposal

Early Reference to Red-light Treatment of Small-pox

THE use of blue light as an anæsthetic and red light to prevent marking from small-pox has aroused some interest within recent times The subjoined extract is from a footnote in Miss Strickland's history of Queen Marguerite of France, and was first published in 1839 According to this quotation from Gaddesden, the red-light treatment would seem to have been known in the days of Edward the First

ALFRED SANG

Garland Nut and Rivet Co, Pittsburg, Pa

WHILE music and sculpture had attained some degree of perfection in England at this time, other arts and sciences were in a strange state of barbarous ignorance The earliest notice of medical practice is to be found, at this era, in the Latin work of Gaddesden, physician at the court of Queen Marguerite This learned doctor, describing his treatment of Prince Edward in the small-pox thus declares his mode of practice —"I ordered the prince to be enveloped in scarlet cloth, and that his bed and all the furniture of his chamber should be of a bright red colour, which practice not only cured him, but prevented his being marked" More by good luck than good management, assuredly, it may be supposed that Gaddesden wished to stare the red inflammation of the small-pox out of countenance, by his glare of scarlet reflections' He adds in his Rosa Anglorum that "he treated the sons of the noblest houses in England with the red system, and made good cures of all" In this childish state was the noble art of healing at the court of Marguerite

The Lyrid Meteors

THERE are other nights besides the usual ones of April 20–22 on which it is desirable that a watch should be maintained for these meteors, and in the present year there are three dates that call for special attention in this respect, viz those of April 14, 18, and 23, as from calculations made by the present writer showers become due on these nights though it will not be possible, owing to the hours of their occurrence, to observe them all from the same station Probably, so far as direct observation is concerned, the general Lyrid maximum will fall on the night of April 23, as its special periods of activity will favour more observers than in the case of the other two displays

The following are the computed times of the various maxima of the anticipated showers —

April 14 7h and 9h 30m. G M T
April 18, 3h 30m and 7h G M T
April 23, 8h 30m and 14h G M T.

The moon will hinder observations most on the night of April 23 but if this night turns out clear, some fine meteors will probably be observed

JOHN R HENRY

GYROSCOPIC APPARATUS FOR STEADYING SHIPS

IN our account of the recent meeting of the Institution of Naval Architects (NATURE, March 28, p. 522) reference was made to the paper read by Sir William White in which he gave particulars of certain experiments carried out on the estuary of the Elbe by means of a torpedo-boat, the *Seebar*, in which Dr Otto Schlick's gyroscopic apparatus was fitted. In our report of the meeting we stated that we should return to the subject, and this we now proceed to do.

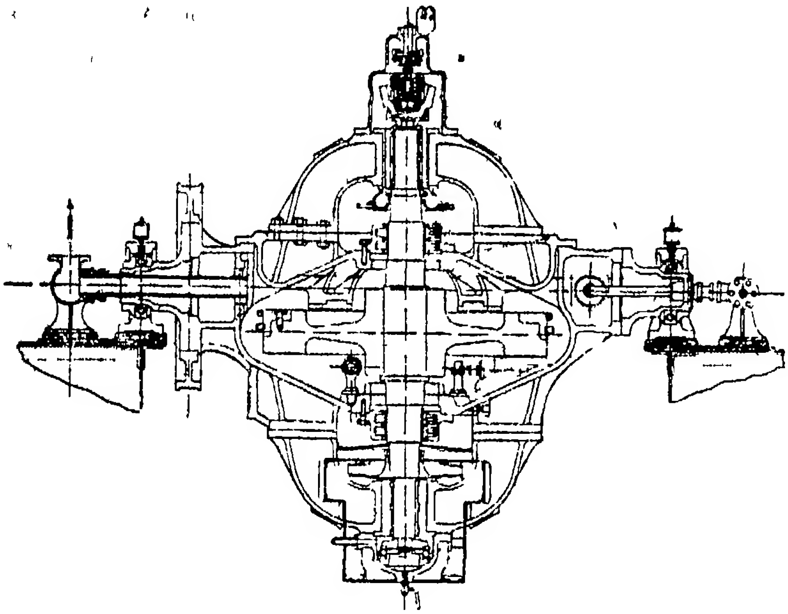

FIG. 1.—Details of steadying apparatus on s.s. *Seebar*. Scale about 1/25th full size.

It may be remembered that three years ago Dr Schlick read a paper at the spring meeting of the same institution on the gyroscopic effect of fly-wheels on board ship, and at the same period he illustrated, by means of models, the system of steadying vessels which he had brought forward. The models were, as Sir William White pointed out, of small inertia compared to the inertia of the gyroscopes mounted in them, and the steadying effect was, therefore, more marked than it would be under the conditions of ordinary working with ships or boats. In these circumstances it is perhaps hardly surprising that a good many persons connected with seafaring looked on Dr Schlick's apparatus as outside the region of useful application; in fact, it would not be an exaggeration to say that the idea was largely considered to be a very pretty scientific "fad."

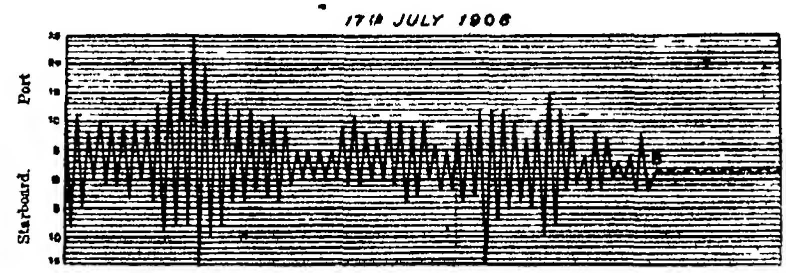

FIG. 2.—Diagram of Oscillations of s.s. *Seebar*.

Dr Schlick, though a man of science, is by no means a "faddist", as the position he holds in the German mercantile marine, and the substantial contributions he has made to the advancement of marine engineering practice sufficiently show, and he determined to prove the soundness of his theoretical investigations by experiment on a practical scale. To this end he acquired the *Seebar*, formerly a first-class torpedo-boat, 116 feet long, 11·7 feet wide, 3·4 feet draught, and of fifty-six tons displacement. Her metacentric height was 1·643 feet, and her period of oscillation (double roll) 4·136 seconds. Into this vessel was fitted the gyroscopic apparatus, of which we give a sectional elevation in Fig. 1. The following are the main particulars:—the outside diameter of the fly-wheel was 1 metre, the weight, without the spindle, 1106 lb., and the peripheral velocity at which it was run 274·8 feet per second, the number of revolutions being 1600 per minute. The fly revolved on a vertical spindle, and was of forged steel; it was enclosed in a cast-iron case, the latter being supported by two hollow trunnions, the common axis of which was in a 'thwartships direction, as shown in Fig. 1. It would have been preferred to have used electric power to revolve the fly-wheel, but as generating machinery was not fitted it was determined to use steam direct, and for this purpose blades were fitted to the periphery so as to work the fly-wheel as if it were a turbine, steam being admitted through the hollow trunnions. For this reason the peripheral speed was less than it would have been had electricity been the motive power and the weight was consequently greater for the production of an equal gyroscopic effect.

It will be assumed for the purpose of this description that the principle of gyroscopic action is known so far as it is generally understood, but those who wish to refresh their memories on this matter would do well to refer to Dr Schlick's paper in the Transactions of the Institution of Naval Architects for 1904. The common centre of gravity of the whole apparatus was, in the *Seebar*, below the axes of the trunnions with the vessel at rest, and the spindle therefore vertical. On rolling motion being set up the spindle would be free to become inclined from the vertical in a fore and aft direction, and, as rolling proceeded, the gyroscopic effect of the fly-wheel would produce longitudinal oscillations of the apparatus having a period depending upon the distance of the centre of gravity below the axes of the trunnions and upon the moment of inertia of the apparatus

about the axis The amplitude of oscillation of the gyroscope, as Sir William White proceeded to point out, depends upon many conditions, among which the period of oscillation and its ratio to the period of rolling of the vessel are important

In order to utilise the gyroscopic effect in checking rolling it is necessary to have a means of braking the apparatus so as to check movement on its trunnions and the rotary motion of the fly-wheel To control the swinging motion a simple band-brake was fitted, the drum for which is shown on the left of Fig 1 In addition to this a socket was fitted on each side of the gyroscope casing below the fly-wheel, the braking effect being supplied by hydraulic power and regulated by a valve With the casing held by the brake the gyroscope would have no effect on the rolling motion, but on the friction band being loosened the casing would oscillate on its athwartship trunnions, and the gyroscopic action would come into play Sir William White says that, when standing upon the deck, which maintained a practically horizontal position, the vessel heaving vertically, it was curious to notice that though the gyroscope might be oscillating longitudinally the impression was conveyed that the vessel herself was pitching

Still-water rolling experiments were made with the *Seebar*, rolling being set up by the crew running from side to side With the gyroscope fixed the period of a complete double roll was found to be 4 136 seconds When the fly-wheel was running at 1600 revolutions per minute, the period was six seconds The boat was next hove down by a crane to an inclination of 10° to 15° from the vertical and when let go the successive extreme inclinations were noted until they fell to about ½°

The still-water rolling experiments strikingly illustrated the enormous extinctive effect of the gyroscope as shown by a diagram given by the author of the paper Selecting two experiments for illustration, it was found that with "an initial angle of inclination of 10° with the gyroscope at rest 20 single oscillations took place before the extreme inclination to the vertical was reduced to half a degree, whereas the same amount of extinction was obtained with little more than two single oscillations when the gyroscope was free to oscillate and the fly-wheel was rotating at 1600 revolutions per minute "

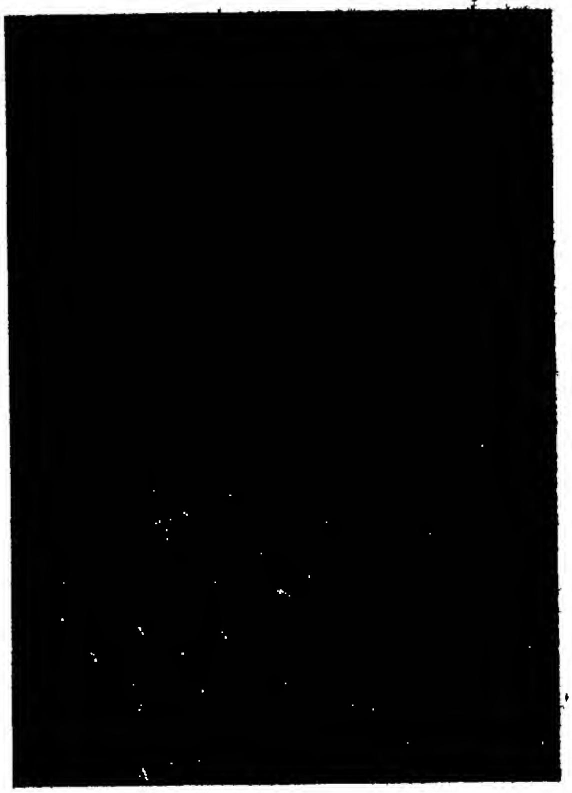
In Fig 2 we reproduce from Sir William White's paper a graphic record of rolling experiments made with the *Seebar* off Cuxhaven The point marked B denotes the time when the brake band was released, the gyroscopic wheel becoming free to swing on its trunnions, and the extinctive forces coming into action The revolutions were 1600 per minute, and as will be gathered, the practical result was to extinguish the rolling motion almost immediately although the vessel was naturally still subject to heaving motion The inclinations were insignificant, varying from about ½° to 1°

Sir William White in his paper discussed the further application of the apparatus to war vessels, and though he did not commit himself to any definite opinion, it may be said that the impression given was decidedly of a hopeful nature In connection with this subject the experiments of Sir John Thornycroft with his steam yacht the *Cecile*, and those of the late Mr Beauchamp Tower with his hydraulic steady gun platform controlled gyroscopically, will doubtless be remembered Particulars of both series of investigations are to be found in the Transactions of the Institution of Naval Architects

G R Dunell

BRITISH NESTS AND EGGS.[1]

THIS handsome and exquisitely illustrated volume (which is practically a new work, so greatly does it exceed its predecessor in bulk and in wealth of illustration) makes its appearance, no doubt purposely, at an opportune time, and if it induces but half-a-dozen collectors in the coming season to devote their attention to photographing the nests of our native birds in place of robbing their eggs, it will have done a great service to British ornithology. According to the letter of an admirer quoted in the preface, such a conversion has already taken place in several instances as the result of the Messrs. Kearton's previous works, and an extension of the new practice may therefore be confidently awaited. Mr Kearton observes that "it is a curious kind of morality that will scorn to steal from the individual



Ptarmigan on Nest From "British Birds' Nests"

and yet rob the community without compunction. Wild birds are national property, and no individual has a right to harm one of them without the sanction of the law to do so " Although this is, no doubt, to a great extent true, it must be remembered that by nature we are all essentially hunters and spoilers, and as many of us, at any rate, have not yet fully imbibed the socialistic spirit, it would not do for the present to be too hard on the egg-collector if he conducts his operations with moderation *Festina lente* is an admirable motto in this and many other matters.

As regards the book itself, a critic is frequently embarrassed as to what he should write from the intrinsic badness of the work set before him, in the present instance the reverse of this is the case, and

[1] "British Birds' Nests, How, Where and When to Find and Identify Them By R Kearton New edition, revised and enlarged. Pp xii+520, illustrated (London Cassell and Co , Ltd., 1907) Price six net

the reviewer scarcely knows how to control his pen so as not to appear unduly laudatory To say that the book is practically perfection is a mild way of putting it, for, as a matter of fact, it is one that can never be equalled or rivalled so long as the copyright of its illustrations holds good, since no other man is likely to undertake the labour and expense necessary to produce a similar series of pictures from nature, even if he had the energy and patience necessary to the task. How great a debt ornithologists and bird-lovers generally owe to the Messrs Kearton (for a large number of the photographs have been taken by the author's brother, Mr Cherry Kearton) it is, indeed, impossible to estimate, and a part of their reward, at any rate, must consist in the pleasure they afford to, let us hope, an ever-widening circle of readers.

Of the photographs of nests and eggs, as well as of those of the parent birds, it is impossible to speak too highly, and where all are on such a high level of excellence it would be almost invidious to select any for special commendation The one here reproduced has been chosen on account of its size rather than from any other consideration The plates of eggs are admirable examples of the best style of three-colour process Taken as a whole, the volume (which is a marvel of cheapness) will probably prove the most attractive natural history book of the year

THE ORIGIN OF "BOTTOM WATERS" IN THE NORTHERN SEAS

A SERIES of valuable tables and charts, in which the results of a great series of observations made in 1901 by Captain Roald Amundsen in the Arctic Seas are summarised, is contained in a monograph recently published[1] These observations are supplemented by, and compared with, results published by other observers, chiefly Russian and Norwegian, and as a collection of facts the little volume is certain to prove of great value to all students of oceanography Dr Nansen's main purpose in the discussion of the observations has been the scientific explanation of the origin of the intensely cold and heavy "bottom waters" found in the basins of the Norwegian seas and North Polar Ocean In discussing the scientific results of the Norwegian North Polar Expedition of 1893–6, Nansen had already dealt with this subject, and reached the provisional conclusion "that the cold bottom water of the Barents Sea is divided into two portions, the northern cold water coming from the sea to the North, North East, and East; and the southern cold water having two or three sources, namely bottom currents from the East and North East, and the surface of the sea itself which is cooled during the winter" In the light of more recent and extensive observations, Nansen has revised his opinion, and puts forward a different explanation of the origin of bottom water This explanation accords with the facts observed, and may be briefly summarised

The conditions required for the formation of bottom water are that near the surface water shall be found having a salinity of about 34 9 per cent, and that during winter this water may be cooled down to $-1°3$ C or $1°4$ C. Its density may thus be between 28 11 and 28 13, and possibly greater, so that it becomes sufficiently heavy to sink The assumed salinity of surface water Nansen thinks will only exist in places where Atlantic water has mixed with Arctic water Further, he considers that when bottom water is being formed there must be no rapid horizontal circulation which would bring in new supplies of relatively warm water As the surface water becomes heavier it sinks, and will be replaced by somewhat warmer water of higher salinity, which in its turn will be cooled until it becomes heavier than the previous surface water, when it will sink still deeper, and be replaced by warmer water of still higher salinity from below The uppermost strata will by this process be gradually increased in salinity, and approach that of the bottom water—about 34.9 per cent The depth of vertical circulation will increase until it reaches down into the typical bottom water, and at that stage all strata from the surface downwards will have attained nearly uniform temperature, salinity, and density Subsequent cooling at the surface will produce water so heavy that it may sink far down into the bottom water, or even to the bottom of the sea

The heaviest sea-water of which Nansen has any knowledge was found at a depth of 120 metres—8 metres above the bottom—off the coast of Nova Zembla in May, 1900, the temperature of bottom water has in some cases approached $-2°$ C with a salinity exceeding 35 per cent and a density of 28 33 The observations made extended to depths of 3000 metres, where the temperature was $-1°1$ C Amundsen reached 2000 metres, at which the temperature was $-1°3$ C

The circulation of bottom water in the Norwegian Sea Nansen describes as follows —The bottom water is chiefly formed and sinks towards the bottom during the winter and spring in the regions between 73° and 76° north latitude, and between 4° west longitude and 4° east longitude From this region it moves along the bottom and spreads out laterally, producing cyclonic movements in the deep strata of the Norwegian Sea During this circulation the bottom water is slowly heated from the underlying warmer sea bottom and from the overlying warmer water In this manner its temperature near the bottom is gradually raised from about $-1°3$ C to about $-1°$ C Nansen estimates that at least two-thirds of the whole basin of the Norwegian Sea is filled with cold bottom water The renewal of the cold bottom water in the basin of the Norwegian Sea must be an extremely slow process, and it has been established by actual observation that the bottom water does not extend across the ridge anywhere between Iceland and Norway, where the temperature is nowhere below zero Further, he thinks that it is very improbable that any bottom water with a temperature below $-1°$ C ever gets across the ridge between Iceland and Greenland

For the North Polar basin Nansen considers the minimum temperature to be between $-0°8$ C and $-0°9$ C, the salinity being about 35 1 per cent If existing observations are confirmed, in his judgment the possibility of a communication between the deep North Polar basin and the deep basin of the Norwegian Sea, as well as of their bottom waters, will be finally excluded In that case he thinks that there are two regions where the bottom waters of the North Polar basin might originate by being cooled down directly through radiation from the sea surface, namely, in the seas north of Spitsbergen and near northern Nova Zembla Nansen is further of opinion that the renewal of the cold bottom water of the enclosed North Polar basin will occur even more slowly than the corresponding renewal in the Norwegian Sea, so that a much smaller quantity of water

[1] "Northern Waters Capt. Roald Amundsen's Oceanographic Observations in the Arctic Seas in 1901, with a Discussion of the Origin of the Bottom-waters of the Northern Seas. By Fridtjof Nansen Pp 154 11 plates. (Christiania Jacob Dybwad, 1906)

will be required yearly to feed the circulation of the cold bottom water in the North Polar basin

This brief outline of the contents of this interesting memoir will give some idea of the thoroughness of its scientific methods and the great labour that has been bestowed upon them

THE COMMEMORATION OF LORD LISTER'S EIGHTIETH BIRTHDAY

THE eightieth anniversary of the birthday of Lord Lister occurred on Friday last, April 5 Many scientific men have had the good fortune to discover the causation of phenomena of immediate practical importance but to few have been vouchsafed the privilege of seeing the results of their discoveries become in a few years of such enormous benefit to their fellow men as those of Joseph Lister No man alive has by a single discovery conferred upon the whole of mankind a greater boon than did the surgeon who discovered the causation of the direful but not unusual *sequelae* of a surgical operation, viz suppuration, septicæmia, secondary hæmorrhage, erysipelas, and hospital gangrene, and who showed that by preventing the access of bacteria to wounds all these diseases could be avoided

It is just forty years since the first papers of Lord Lister dealing with his discoveries were published in the *Lancet* How the best skill of the surgeon was baffled by these wound infections and the whole development of surgery prevented may be realised by a quotation from a leading article in the *Lancet* written at the time of the publication of one of Lister's earliest papers in 1867

> The mortality of compound fractures of amputations and operations and of lithotomy in our larger hospitals, both provincial and metropolitan, is something frightful And the occurrence of death with symptoms of blood-poisoning is unfortunately not confined to cases of serious operation but happens ever and anon in operations in themselves slight The risk of blood-poisoning is indeed now the one great opprobrium of surgery There is no limit to the operative feats of surgeons, but there is a miserable and serious risk in every case, especially in hospitals, of the occurrence of fatal after-consequences against which—until now at least—we have had little or no power of resistance

The story of the discovery of antiseptic surgery was briefly told by Lord Lister himself in the third Huxley lecture delivered in 1900 In this lecture Lord Lister explained how by the time he became a house-surgeon at University College he was already endowed with a love of physiology and a first rate microscope The former he owed to the inspiration of Prof Sharpey and the latter to his father who did so much to raise the compound microscope from little better than a toy to the powerful engine for investigation which it then was As a young surgeon his attention was immediately turned to the study of those scourges of surgery, suppuration pyæmia and hospital gangrene During the next ten years he made a number of investigations upon the early stages of inflammation and the healing of wounds He was early led to the conclusion that suppuration and septic diseases were due to a poison acting locally and again and again he searched with the aid of the microscope the discharges from wounds in the hope of discovering some *materies morbi* of an organised kind

The idea that wound infections were of parasitic origin although the parasite escaped detection was early in his mind, so that when the epoch-making discoveries of Pasteur on the nature of fermentation and putrefaction were published Lister was prepared to appreciate the analogy between these phenomena and those of wound infection. Guided by this analogy, he devised methods to prevent the entrance of germs to wounds, and was immediately successful in obviating the evil effects hitherto so generally attendant upon the simplest operation.

The actual methods employed have undergone some modifications and simplification in accordance with the development of knowledge during the last fifty years, but the principle to protect wounds from the access of germs "by means which shall disturb the tissues as little as is consistent with the attainment of the essential object" retains its full value at the present time

Lord Lister has been the recipient of many honours bestowed upon him by every civilised community, but it was widely desired that his eightieth birthday should be suitably commemorated It was considered by some of his admirers that this could best be done by the re-publication, by subscription, of his collected work in suitable form Invitations were accordingly issued to a number of scientific and medical men, both at home and abroad, to form themselves into a committee for this purpose The invitations have met with a warm response, and the committee may be described as an international one

A meeting of this committee took place on Thursday, April 4, at the Royal College of Surgeons, which was presided over by Mr Henry Morris, the president of the college It was unanimously resolved to ask Lord Lister to allow the committee to re-publish his scientific papers, and a small editorial committee was chosen to carry out this object The following letter was sent to Lord Lister from the committee —

DEAR LORD LISTER,

A desire having been widely felt that the eightieth anniversary of your birthday should be marked in some special manner a committee of your professional brethren both at home and abroad was formed to consider in what way this could best be done

This committee met to-day at the Royal College of Surgeons when it was unanimously resolved to ask you to allow them to commemorate the occasion by collecting and publishing your various scientific papers in book form In anticipation of your acquiescence an editorial committee was appointed to carry out such publication

At the same time those present at the meeting wished to convey to you their warmest congratulations on this occasion, and gratefully to acknowledge the debt which the medical profession, and, indeed, the whole world, owe to you for the work which you have done That you have lived to see such enormous advances in surgery and medicine flow from your work must be a source of great gratification to you and the committee hope that you may be spared to see still many further advances follow therefrom

I remain, dear Lord Lister,
Yours sincerely
(Signed) HY MORRIS
President, Royal College of Surgeons, Chairman

Lord Lister replied to the letter as follows —

DEAR MR MORRIS,

I duly received your letter yesterday informing me of the decision of the general committee to ask me to allow them to commemorate the occasion of my eightieth birth day by collecting and publishing my various scientific papers in book form

This proposal is almost overwhelming in its kindness, and I expressed to the deputation which met here in the morning my profound sense of gratitude This surpassingly generous offer is extremely gratifying to me

Believe me,
Very sincerely yours,
(Signed) LISTER

It is proposed to issue the collected papers in two quarto volumes of about 450 pages each The volumes will contain a portrait of Lord Lister, and will be prefaced by a short account of the development of Lister's ideas and work and their relation to the growth of knowledge of infectious processes They will be published at a subscription price of one guinea for the two volumes

NOTES

SIR JAMES DEWAR has been appointed a corresponding member of the Royal Academy of Sciences, Denmark

THE U S Congress has voted 20,000*l* for the erection of a monument to Christopher Columbus at Washington

PROF S. P THOMPSON, F R S, has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of three persons "of distinguished eminence in science, literature, the arts, or for public services"

MR J DE GRAAF HUNTER, assistant in the physics department of the National Physical Laboratory, has been nominated by the India Office to the post of mathematical expert to the Survey of India

THE monument erected by subscription in the garden of the Paris Institut national agronomique to Eugène Risler, the director of the institute from 1879 to 1900, was unveiled by M Ruau, the French Minister of Agriculture, on March 24

THE *British Medical Journal* states that a laboratory for the study of human nutrition is to be built by the Carnegie Institute of Washington on a site adjacent to the Harvard Medical School The work will be under the direction of Prof F G Benedict, of Wesleyan University

IN many places the rainfall measured already this month is greatly in excess of the aggregate measurement for the whole of March On the night of April 6–7 there was a somewhat heavy fall of snow over the south of England, and at Warlingham in Surrey, the ground was covered to the depth of 6 inches In London, snow fell for some time in the early morning of Sunday, April 7, and the rainfall as yet this month already exceeds an inch Thunderstorms have also occurred in different parts of the country Notwithstanding that the aggregate rainfall at Greenwich for the first three months of the year was deficient by 1 63 inches, the total for the six winter months, October–March, was 0 75 inch in excess of the average for the past sixty years

THE earthquake at Bitlis on March 29, briefly recorded in last week's NATURE, appears to have been of unusual severity, and was registered by seismographs at several distant stations The earthquake occurred at 10 a m on March 29, no fewer than fourteen severe shocks being felt on that day Shocks stronger than the first were felt at Bitlis all night on March 31, resulting in fresh casualties and further destruction of houses Violent shocks of earthquake were felt on April 2 in the island of San Miguel, Azores, particularly in the town of Villa Franca, which was formerly destroyed by earthquake

THE two Royal medals of the Royal Geographical Society have been awarded, with the King's approval, to Dr Francisco Moreno, who for more than twenty years has been personally occupied in the work of South American exploration, and Captain Roald Amundsen, the Norwegian explorer who recently completed the North-west Passage for the first time in a ship, and made observations in the neighbourhood of the North Magnetic Pole The Murchison bequest of the society has been awarded to Captain G E Smith, for his various surveys in British East Africa the Gill memorial to Mr C Raymond Beazley, for his work in three volumes on "The Dawn of Modern Geography", the Back bequest to Mr C E Moss, for his researches on the geographical distribution of vegetation in England, and the Cuthbert Peek fund to Major C W Gwynn, C M G, R E, for the geographical and cartographical work carried out by him in the Blue Nile region and on the proposed Sudan-Abyssinian frontier

To the long list of eminent men of science that have lately been lost to France by death must be added the name of Colonel Laussedat, for many years the director of the Conservatoire des Arts et Métiers More than sixty years ago he began his public career in the École Polytechnique, and his long life was one of successful achievement He served his country both in the field and in the study During the siege of Paris he had charge of the optical contrivances for maintaining communications with the outside world, and later at the close of the war, he was a member of the commission for arranging the new frontiers of the country Besides filling the office of professor of geodesy, he was at different times member of many committees and numerous commissions, where his experience knowledge, and ingenuity were gratefully acknowledged But it is in the department of photography and in its applications to scientific purposes that he will be longest remembered If he did not originate the application of photography to surveying and photogrammetric inquiries he so encouraged its employment, improved its methods, and demonstrated its usefulness that he won for it a foremost place in the training of every modern topographer Colonel Laussedat was a member of the French Academy and of many learned societies in his own and other countries

As previously announced the annual meeting of the Iron and Steel Institute will be held on May 9 and 10 At the opening meeting, the retiring president, Mr R A Hadfield, will induct into the chair the president-elect Sir Hugh Bell, Bart, the Bessemer gold medal for 1907 will be presented to Mr J A Brinell (Stockholm), and the president will deliver his inaugural address Among the papers to be submitted on May 9 and 10 are the following —The use of steam in gas producer practice Prof W A Bone F R S and R V Wheeler, the influence of process of manufacture on some of the properties of steel F W Harbord, the ageing of mild steel, C L Stromeyer carbon-tungsten steels, T Swinden, the nomenclature of iron and steel report of a committee of the International Association for Testing Materials Reports on research work carried out during the past year will be submitted by C A F Benedicks (Sweden) O. Stutzer (Germany), E F Law (London), E Hess (United States) P Breuil (Paris), H C Boynton (United States) L Guillet (France), W H Hatfield (Sheffield) A Campion (Glasgow), F G L Roberts (London), E A Wraight (London), and W Rosenhain (Teddington) Carnegie research scholars The annual dinner of the institute will be held in the Grand Hall of the Hotel Cecil on May 10, under the presidency of Sir Hugh Bell, Bart The council has accepted an invitation to hold the autumn meeting of the institute in Vienna on September 23–25 After the meeting there will be alternative excursions to

Bohemia and Styria, by invitation of the Prague Iron Industry Company and the Austrian Alpine Mining Company respectively. An invitation has also been received from the Witkowitz Mining and Ironworks Company to visit their works.

In an elegant little pamphlet entitled the "Birdland Booklet," Messrs. Sanders and Crowhurst direct the attention of amateur photographers to the advantages of their reflex birdland camera.

Most of the articles in Nos. 5 and 6 of the *Bulletin International de l'Académie des Sciences de Cracovie* for 1906 relate to physiological and chemical subjects, but Mr. W. Kulczynski contributes a continuation of an account of certain arachnid groups, dealing in this instance with the European representatives of the genus Amaurobius. The article, which is in Latin, is illustrated with two plates, and contains descriptions of twenty species, one of these being new.

A specimen of the so-called "sea-mignonette" (*Primnoa reseda*) dredged in the Færoe Channel, has enabled Prof. J. A. Thomson in the Proceedings of the Royal Physical Society of Edinburgh, vol. xvii., No. 2, to state that this gorgonian is one of the most gorgeously coloured members of the British fauna, being naturally a brilliant salmon pink, although the tints rapidly fade after exposure to light. Prof. Thomson has also discovered that this species, the only member of its genus, is viviparous.

The appearance of the first part of a work entitled "The Book of the Open Air," edited by Mr. Edward Thomas, and published by Messrs. Hodder and Stoughton, may apparently be taken as an indication of an increasing appetite on the part of a considerable section of the public for anything connected with country life and popular natural history. The illustrations, of which fifty are promised, are all to be coloured, and the work is to be completed in a dozen shilling parts. The illustrations of scenery in this part are simply exquisite, and, even though the naturalist may consider those of animals a little too "artistic" in colouring, if the present standard is maintained the volume will be a marvel of cheapness. The names of Messrs. W. H. Hudson and J. C. Tregarthen are alone sufficient to indicate that the letterpress will not be deficient in interest.

The list of New Guinea mammals published by Dr. F. A. Jentink in vol. xxviii. (pp. 161 *et seq.*) of Notes from the Leyden Museum presents a remarkable contrast in point of extent to those in most text-books, comprising no less than 127 species and subspecies. The number recognised by Dr. Wallace in his "Malay Archipelago" (1869) is, for instance, only seventeen, while even so late as 1897 Dr. K. M. Heller could enumerate not more than seventy species from the whole of the Papuan Islands. Probably a few of the forms entered in Dr. Jentink's list are not entitled even to subspecific rank, but, discounting this, the length of the list is sufficient to refute the old idea that New Guinea is very poor in mammals. As to the future, the author is of opinion that exploration of the practically unknown mountain interior of New Guinea—a country larger than Borneo, and double the size of Great Britain—will probably yield a number of new forms.

The latest issue (vol. iv., parts xiv. and xv., published together) of *Spolia Zeylanica* contains an illustrated account by Dr. Günther Enderlein of a large number of new minute insects belonging to the same group of Neuroptera as the European book-lice and death-watches. The few Ceylonese forms previously known were chiefly those described by Hagen in the years 1858 and 1859, but Dr. Enderlein has been enabled to reveal the existence of quite a host of these tiny insects, referable to a number of new generic types. In place of grouping all these "scaly-winged Copeognatha" in the single family Psocidæ, as is done by Dr. David Sharp, the author refers them to three distinct families, confined almost exclusively to the tropics, the only exceptions being one species from Japan and two from North America. Of the nineteen recognised genera, fourteen are named by Dr. Enderlein. In general appearance and the beauty of the pattern and colouring of their scale-clad wings (exquisitely shown in the coloured plates illustrating the memoir), these insects recall the Microlepidoptera. The use of the term "woodlice" as their popular designation is, as the editor of *Spolia Zeylanica* points out, barred by the employment of that name in another sense.

A very important paper, by Profs. J. T. Wilson and J. P. Hill, on the fœtal dentition of the Australian duck-bill, or platypus (Ornithorhynchus), is published in the February issue, vol. li., part i., of the *Quarterly Journal of Microscopical Science*. The authors announce the discovery of tooth germs belonging to at least two distinct dentitions. What may be called the second dentitions seems to comprise five pairs of teeth in each jaw. Of these, the last three clearly have deciduous predecessors, and they may therefore be regarded as molars, while if such predecessors are absent in the two anterior teeth (a point not yet definitely ascertained), these will be premolars. It is noteworthy that of the three functional teeth in the upper jaw, the first, and smallest, pair belongs to this presumed premolar series, which is unrepresented in the functional lower teeth. Very noteworthy is the discovery that the vestigial precursors of the large functional molars take the form of a much more numerous series of dental rudiments, each corresponding approximately with one of the cusps of their complex successors. "The mode of development of the successional molars ... is decisive against the occurrence of any fusion-process, but the relation of the two series in the molar region cannot but be regarded as suggestive of some sort of phylogenetic substitution of a small number of compound teeth for a large number of simple teeth—a process which must be reckoned as covering the fundamental idea of concrescence."

The Board of Agriculture and Fisheries has published a new edition of the leaflet on the black currant mite, in which information on the treatment of this pest with lime and sulphur has been incorporated. Fruit growers whose bushes have been attacked with the mite are advised to experiment with this process. Copies of the leaflet may be obtained gratis and post free on application to the Secretary of the Board of Agriculture and Fisheries, 4 Whitehall Place, London, S.W. Letters so addressed need not be stamped.

The general conclusions derived from former attempts to grow the opium poppy with a view to the production of alkaloids have been adverse to the profitable cultivation of the plant in Europe. A recent experiment made by Dr. H. Thoms at Dahlem, near Berlin, of which an account is published in *Berichte der deutschen pharmaceutischen Gesellschaft*, vol. xvii., promises no better. The fruits of German varieties gave considerably higher yields than the

fruits of plants raised from imported Asiatic seed, but the cost of labour proved prohibitive, further, the yield was found to be uncertain.

WHETHER it is regarded as an exposition of the new rules for botanical nomenclature or as an authentic revision, the thanks of the botanical community are due to the trustees of the British Museum for publishing, and to Dr. A. B. Rendle and Mr. J. Britten for compiling, a list of British seed plants and ferns to conform with the decisions adopted at Vienna in 1905. The sequence of orders follows Bentham's "Handbook", the limitation of species is based on Messrs. Groves's revised edition of Babington's "Manual," while additional insertions correlate the names given in Bentham's "Handbook," Hooker's "Student's Flora," and the previous edition of Babington's "Manual." The form is similar to that of the London Catalogue, which it presumably will supplant.

WHILE studying the subject of polymorphism in the Hymenomycetes, a basidiomycetous subclass of fungi, Mr. G. R. Lyman has added to our knowledge of subsidiary spore-forms. It was found that oidia are commonly developed upon the mycelia in the Polyporaceæ and Agaricaceæ, but rarely or never in the lower orders. Chlamydospores previously recorded for a few agarics and many of the Polyporaceæ were produced under cultivation on the mycelia of species of Corticium and some of the Hydnaceæ. Conidia were most frequently observed in the Thelephoraceæ. Peculiar reproductive structures not unlike immature ascocarps, receiving the name of bulbils, were discovered in *Corticium alutaceum*, this being the first record for a basidiomycetous order. The paper is published in vol. xxxiii., No. 4, of the Proceedings of the Boston Society of Natural History.

THE issue of *Irish Gardening* for the current month contains an article by Dr. G. H. Pethybridge on the American gooseberry-mildew in Ireland. This mildew (*Sphaerotheca mors uvae*) was the subject of an article in these columns on December 13 last (vol. lxxv., p. 160), and of a letter from Mr. E. S. Salmon in our issue for January 10 (vol. lxxv., p. 247). Dr. Pethybridge says that everyone who has come into working contact with the disease in Ireland admits its destructive nature. Last year nineteen counties out of Ireland's thirty-two had records of the disease, and the ninety-eight localities in which it has been reported since the first case in 1900 are indicated on a map accompanying the paper. There are now about 100 cases of the mildew in Ireland, and to state that the disease exists "in hundreds of gardens" in Ireland is an unnecessary exaggeration. The greatest stronghold of the disease is at present in the north-east of Ireland, more or less in the neighbourhood of the first outbreak, and many of these cases have undoubtedly arisen by the transference of the spores by natural agencies from one garden or plot to neighbouring ones. Corresponding to the increased number of cases during last summer, there has been an increased effort to eradicate the disease, especially by spur pruning and burning, and it is to be hoped that systematic spraying with potassium sulphide solution will be carried out in every garden or plot in which the disease existed last summer. In order to settle the question as to whether spraying is of use or not in combating the disease in Ireland, what is wanted is a carefully carried out set of experiments with the necessary controls, and Dr. Pethybridge understands that the Irish Department of Agriculture has such experiments in hand for the coming season.

THE Home Office reports on the Wingate Grange colliery explosion on October 14, 1906, have been issued as a Blue-book (Cd. 3379). It is shown that the explosion, which caused forty-four deaths, was due to coal dust and not fire-damp, and that the cause of the explosion was a charge of geloxite, a permitted explosive, fired by means of a fuse. It is evident that, as coal mines are becoming deeper and drier, and larger areas are being worked from a pair of shafts, care should be taken to mitigate the dangers arising from the presence of coal dust. For this purpose steps should be immediately taken to make obligatory the removal of all coal dust from the in-take air ways and mechanical haulage roads of collieries. Attention is directed to the Blue-book by Mr. John Wilson, M.P., in his circular to the Durham Miners' Association, and also by Mr. Thomas Burt, M.P., in his monthly circular to the Northumberland Miners' Association.

THE increasing application of electric power to mining operations was clearly shown in two papers by Mr. M. Kellow and Mr. A. H. Preece read before the Institution of Civil Engineers on March 26. Mr. Kellow described a hydroelectric plant containing many features of novelty installed at a Welsh slate mine. The scheme has been carried out in the Croesor and Cwmfoel valleys, in the vicinity of Snowdon, and includes all the essentials of a complete power system, it being the first example of so high a head of water as 860 feet being utilised in the United Kingdom. The advantages of the three-phase system as applied to slate mining were summarised, and the plant installed for mill driving, winding, haulage, pumping, and lighting at the Croesor slate mine was described. In the second paper Mr. Preece dealt with electrically driven winding gear, and referred to various points relating to the cost of electric power in mines.

THE Geological Survey of Canada has issued the annual report of the section of mines (No. 928), giving the completed and revised information descriptive of the mineral industries of Canada for 1904. The report has been drawn up by Mr. E. D. Ingall. The Geological Survey has also issued reports on the Chibougamau mining region in the northern part of the province of Quebec, by Mr. A. P. Low (No. 923), and on the Rossland mining district, British Columbia, by Mr. R. W. Brock (No. 939). The former, which covers sixty-one pages and is accompanied by a coloured geological map on a scale of four miles to the inch, records the discovery of an area of serpentine rocks containing asbestos of excellent quality, and the finding of a large vein of gold-bearing quartz and numerous indications of copper ore. The latter report, which is of a preliminary nature, clearly shows the development and progress of gold, copper, and silver mining in the Rossland district. We have also received a somewhat belated report (No. 908, Ottawa, 1905) on recent mineral discoveries on Windy Arm, Tagish Lake, Yukon, by Mr. R. G. McConnell. The deposits consist of quartz veins, the principal values in which are in silver.

A VALUABLE paper on the testing of electric machinery and of materials for its construction, read by Prof. Epstein before the Institution of Electrical Engineers, is published in full in the last issue (vol. xxxviii., February) of the Journal of the Institution. The paper was the direct outcome of the information supplied to one of the Engineering Standards Committees during the last eighteen months by the author, and is exceptionally interesting from both the purely scientific and practical engineering points of view. Prof. Epstein describes fully the various methods of testing the materials used in the manufacture of

electrical machinery and the uses to which the results obtained in the laboratory are put in practical design That these results must not always be blindly followed is shown by the fact that in some cases where the efficiency obtained in a laboratory test is very high, when the material tested is taken for practical use it is of no value for manufacturing purposes owing perhaps to porosity or other defect Consequently the paper is of special value in that the results of many years' work are given, thus providing what is probably the most accurate data for the design of modern electrical machinery Every material used in the construction of the dynamos, motors transformers &c of the present day has been scientifically tested, and the results are now classified The various classes of iron, copper, carbon, and insulating material have been thoroughly sifted so that efficient and commercial combinations have been secured

FROM Messrs Adam Hilger Ltd we have received a brief description of the 1907 model of their well known wave length spectroscope The growing demand for these spectroscopes by education authorities, research workers, and technical experts has enabled the makers to add numerous improvements, and, from the description the present model appears to be mechanically and optically ideal The telescope and collimator have a focal length of 11½ inches and an aperture of 1¼ inches The prism-train effectively consists of two 30° prisms and one 90° reflecting prism, but is actually made in one piece The bearing part of the screw on which is fixed the helical drum on which the wave lengths are engraved is especially worked and hardened and presses against a hardened steel plug the surface of which is optically polished thus imperfect contacts and periodic errors are eliminated These improvements have necessitated slightly increased prices the present cost of the spectroscope with a prism of 1.65 refractive index for D, being 25*l*. and for a refractive index of 1.74 27*l*. 15*s*.

THE Perkin memorial committee has issued as an attractive volume appropriately bound in mauve an account of the proceedings in connection with the International Celebration of the Coal-tar Colour Jubilee with which we dealt in an article in our issue for August 2, 1906 (vol lxxiv, p 318), and in numerous notes published from time to time The jubilee volume contains the special report by the *Times*, the whole of the telegrams, letters, and addresses received by Sir W H Perkin, F R S, several of the speeches made at the Royal Institution and at the dinner at the Hôtel Métropole and a report of the celebrations held in America It is illustrated by reproductions of the portraits of Sir W H Perkin and of his father and brother views of the Greenford Green Works and photographs of the oil portrait and marble bust presented to Sir W H Perkin by international subscription The volume forms a fitting memento of an important and interesting event

THE coefficient of expansion of fused quartz is the subject of a paper by Mr Howard Minchin in No 1 of vol xxiv of the *Physical Review* the determinations were made by the interference method over ranges of temperature between +16° C and +1000° C, and the conclusion is drawn that between these limits expansion is uniform the mean coefficient α having the value 0.440×10^{-6} In No 1 of vol ix of the *Verhandlungen* of the German Physical Society, Dr Karl Scheel publishes a communication from the Physikalisch-Technischen Reichsanstalt dealing with the expansion of crystalline quartz in the direction of the axis, and of platinum, palladium, and quartz glass between the temperatures of −190° C and +100° C These determinations were also made by the optical method The coefficient of expansion of quartz glass is given by the equation

$$l_t = l_0(1 + 0.217\ 10^{-6}\ t + 0.002379\ 10^{-6}\ t^2),$$

and it is seen that, between the interval −190° C and +16° C instead of an expansion occurring, a contraction of 41 μ per metre is observed The curve of expansion of quartz glass thus shows a minimum at a temperature of about −46° C

A CORRESPONDENT suggests that the passing allusion made to the collection of ship models in the Victoria and Albert Museum, in the review of Sir George Holmes's book in NATURE of March 28 (p 506), may lead readers to suppose that no models of warships are contained in the collection As a matter of fact, there is a section devoted to warships, and including a number of models lent or given by private firms

THE first part of the third edition of Prof M Lévy's well-known work on "La Statique graphique et ses Applications aux Constructions" has been published by MM Gauthier-Villars, Paris Although some changes have been made, in details the work remains substantially the same The part just received deals with the principles and applications of pure graphic statics, and is published in two volumes—one containing the text (pp xxx+598) and the other (Plates xxv) the figures

IN the second revised edition of "Die Spiele der Tiere," just published by Mr Gustav Fischer, Jena, Prof K Groos has made numerous changes The book is full of interesting incidents and explanations relating to the play of animals, and appeals both to the naturalist and psychologist A translation of the original edition into English appeared in 1898, and was described in these columns (vol lviii, p 410)

EIGHT new volumes (Nos 151–8) of Ostwald's scientific classics have been received from Mr W Engelmann, Leipzig The volumes contain papers, in German, by Poinsot (1809), Cauchy (1811), J Bertrand (1858), Cayley (1859), Grotthuss, on electricity and light (1808–1819), Hankel (1870), Dutrochet (1824), Zamboni, Sella, Jacobi, and Toepler (1866–7) Each volume includes editorial notes, as well as reprints or translations of original papers, so that students of science familiar with the German language are provided by Prof Ostwald's series with a ready means of referring to the works of the old masters and receiving inspiration from them

THE Country Press, of Kensington, London, W, has issued two more packets of nature-study post-cards One packet includes facsimiles of six British trees in winter, the other provides natural figures of boles of the same trees The packets are issued at 6*d* each

MESSRS J AND A CHURCHILL have published a fifth edition of "Elementary Practical Chemistry," by Dr Frank Clowes and Mr J B Coleman The book is published in two parts, the first dealing with general chemistry and the second with qualitative and quantitative analytical chemistry In the present edition the whole of the matter has been revised, and alterations and additions have been made

WE are indebted to the publisher, F Tempsky, of Vienna, for a copy of the fifth edition of Graber's "Leitfaden der Zoologie," edited by Dr Robert Latzel This well-known illustrated text-book is intended primarily for use by the higher classes of the middle schools

OUR ASTRONOMICAL COLUMN

COMET 1907*a*.—No. 4165 (March 26) of the *Astronomische Nachrichten* contains a new set of elements and an ephemeris for comet 1907*a* (Giacobini), calculated by Herr M. Ebell from places observed on March 9, 12, and 16. According to the elements, the perihelion passage took place on March 26, and, as shown by the ephemeris, the comet's brightness is decreasing, now being less than half what it was at the time of discovery. The position of this object for April 11 is $\alpha = 6h.\ 14m.$, $\delta = +4^\circ\ 47'$, and the comet is travelling in a nearly due northerly direction, its calculated position for May 6 being 6h. 10m. $+13^\circ\ 42'$.

THE BRIGHTNESS OF THE SKY NEAR THE SUN'S LIMB.—With an apparatus described in No. 4164 (March 25) of the *Astronomische Nachrichten*, Prof. Ceraski, at Moscow, determined the relative intensities of the light at the sun's limb and the atmospheric illumination very near the limb on November 3 and 4, 1906. On the former date the mean value of the ratio $\frac{\text{edge of} \odot}{\text{atmosphere}}$ at the east and west limbs was 31.4, and on November 4 it was 38.4, values far below those which Prof. Ceraski expected to find.

Prof. Ceraski points out that this ratio might be employed as a term of comparison in evaluating the relative intensity of the corona. Using the method described by him in No. 4106 of the *Astronomische Nachrichten*, the coronal light could be compared with that of a standard lamp, which might, after the eclipse, be measured against the illumination of the atmosphere at a determined point in the sky. Thus the illumination of the sun's edge could be compared indirectly, in graduated steps, with that of the corona.

RADIAL VELOCITY OF η PISCIUM.—This star was announced by Mr. Lord as a possible spectroscopic binary having a long period, but Prof. Campbell was unable to find any variation in the line-of-sight velocity. The binary character is now confirmed by plates secured at the Dominion Observatory at Ottawa, the range of velocity so far detected being from +5.4 km. to +21.4 km. per second, and there are indications that the period is a comparatively short one.

α Draconis has also been observed, and the velocity curve practically completed; the period is between fifty and fifty-one days, and the velocity ranges from −53 km. to +35 km. per second.

In the case of ι Orionis, a considerably larger range of velocity than that announced by the discoverers was found, that already observed extending from −50 km. to +100 km. (the Journal R.A.S. Canada, No. 1, vol. i.).

SIMULTANEOUS OBSERVATIONS OF JUPITER.—In the *Bulletin de la Société astronomique de France* for December, 1905, it was suggested that simultaneous observations of Jupiter should be made by as many volunteer observers as could be obtained, and that the results, obtained with many different kinds of instruments and under varied conditions, should be communicated to and coordinated by the society.

One hundred and seventy-two observers made observations at prearranged hours on various dates between January 2 and 20, 1906, and the first batch of results is now discussed by M. Mascart in the April number of the *Bulletin*, the general conclusions derived from all the observations on one day being given, together with reproductions of the original drawings for January 2, 3, 4, and 5, 1906.

THE SUN AS A VARIABLE STAR.—At the meeting of the Royal Astronomical Society held on March 8 Prof. Turner briefly discussed the light curves of a number of variable stars, and showed that there existed a sequence in their forms. In most cases the minimum falls later than mid-way between two maxima, in others earlier, and on arranging the curves of thirty-one variables it was found that the sun falls into the sequence. Seeking some explanation for this arrangement, Prof. Turner has evolved the interesting suggestion that the form of the curve may to some extent, depend upon the position of the star's axis in regard to the line of sight; thus we view the sun from a point lying nearly in the plane of its equator, but the poles of other stars may be turned towards us, whilst in other cases we may be looking normally at mid-latitudes.

An analysis, from this point of view, of the suitable data given in Chandler's catalogue of variable stars led to the tentative result that whilst the stars where we look directly at the equator are distributed in all galactic latitudes, those of which we see the polar regions are absent from the neighbourhood of the galactic poles. As a purely speculative interpretation of this difference, Prof. Turner suggests that the axes of the stars may be nearly parallel to the plane of the Milky Way, an arrangement which would, of course, account for the result found (the *Observatory*, No. 382, April).

EFFECTS OF PRUNING ON FRUIT TREES.

THE scientific work carried on at the Woburn Experimental Fruit Farm, by the Duke of Bedford and Mr. Spencer U. Pickering, F.R.S., is of great value to horticulturists who usually follow rule-of-thumb methods in much the same way as the British farmer cultivates his crops. The fifth report of the Woburn Fruit Farm, noticed in NATURE of September 7, 1905 (vol. lxxii., p. 461), showed that several cherished ideas as to the proper treatment of fruit trees need modification, and that operations which are generally supposed to be beneficial to growth and fruit-bearing are really prejudicial to both. Measurements of leaves, trees and fruits, and weighings of the fruit, led to the conclusions that heavy thinning of the fruit is of no advantage, hard pruning is unprofitable, summer pruning is undesirable, and root pruning injurious. An explanation was also found of the fact that carelessly planted trees, though weak at first, ultimately make more growth than trees carefully planted.

The observations described in the fifth report of the Woburn Fruit Farm have since been extended, and the new results and conclusions are dealt with in the seventh report recently issued.[1] As the conclusions are based on experimental evidence, they are, of course, of far greater value than mere expressions of opinion, and though they apply only to particular trees in a particular soil, they suggest that the ways of the practical gardener are not always wise. The empirical horticulturist believes that "growth follows the knife," but by measuring and weighing trees it has been found that the less a fruit tree is pruned the larger and heavier it becomes, even when allowance is made for the amount of wood removed in the annual pruning of the normal trees. The fruit crops of trees are also increased as the amount of pruning is diminished, so it appears that the less pruning done the better is the result both as regards growth and fruit.

These conclusions, however, apply only to healthy and established trees. Transplanted, injured, or ailing trees may be regarded as prematurely old trees which tend to form an excessive number of fruit buds and increased wood formation. The obvious way to prevent this is to prune hard, and the experiments at Woburn show clearly that if transplanted trees, that is, trees which have been checked in their development, are cut back at once the operation results in the starting of many dormant buds followed by a clean, vigorous growth. Hard pruning also results in increased branch-formation in the case of mature trees, the effect being thus the opposite to what is found when the pruning is on young trees in the full vigour of growth.

The experiments show, in fact, that with trees, as with animals, there are certain periods in their life-history characterised by certain distinct differences of behaviour. All the results obtained at Woburn can be explained by remembering that any cause which disturbs the balance between the root and branch systems at any period of growth is followed by an effect which will adapt the organism to the new condition. The observations are thus not only of importance to practical horticulturists, but are also of scientific interest. The summary of the report, re-

[1] Seventh Report of the Woburn Experimental Fruit Farm. By the Duke of Bedford, K.G., and Spencer U. Pickering, F.R.S. Pp. 56. (London: Eyre and Spottiswoode, 1907.) Price 1s. 6d.

printed below by permission of the authors, presents the results in a convenient form, but a study of the report itself is necessary to appreciate the value of the experiments upon which the conclusions are based.

Records have been kept during the last twelve years of the behaviour of apple trees when pruned to different extents. The trees were chiefly dwarf trees on the paradise stock, and the main series of experiments were made on three varieties, possessing very different habits of growth. Measurements of the height of the trees, the spread of the branches, and the diameter of the stems led to the conclusion that the less the tree was pruned the larger did it become, and this conclusion has now been confirmed by lifting more than half the trees and ascertaining their weight. At the end of twelve years (the trees then being fifteen years old), those which had not been pruned at all were 20 per cent. heavier than those which had been moderately pruned, whilst those which had been hard-pruned were 16 per cent. lighter. The difference in weight between the unpruned and moderately pruned trees was too great to be accounted for by the weight of wood removed in the pruning, so that pruning not only does not increase the actual size of a tree, but it results in less new wood being formed.

These results were further established by pruning to different extents similar branches on the same tree. The less the pruning done the greater was the number, length, and weight of the new shoots formed, and the greater also, was the increase in girth of the original branch.

From every point of view, therefore, the pruning of a healthy, growing tree seems to be inimical to wood formation.

It is as regards the crops, however, that a reduction of pruning shows to greatest advantage. With the dwarf apple trees, the crops during the first five years were more than twice as great from the unpruned trees as from the moderately pruned ones, and more than three times as great as from the hard-pruned ones; in the second period of five years the differences were still greater, and in the twelfth year (when, however, one variety only was in bearing) the unpruned trees yielded nearly three times as much as the moderately pruned ones, and the hard-pruned trees had practically no crop at all. Similar results were obtained during the past season with trees of fifty three and eighty varieties on the crab and paradise stocks respectively, the crops from moderately and hard pruned trees being in the proportion of three to one in both cases. There was no appreciable difference in the size of the fruit from trees pruned to different extents, so that the values of the crops were proportional to the weights. The trees, however, were not allowed to overbear, the fruits being thinned to two to the truss.

Confirmatory evidence of the antagonism of pruning to fruiting was obtained by counting the fruit-buds formed on similar branches of the same tree, which had been cut back to different extents.

All these results refer to healthy trees which are still young enough to be growing vigorously. With a tree which is older, and has attained maturity, the results are somewhat different, not as regards fruiting, but as regards branch formation. With a tree of this age branch-formation under natural conditions, has ceased, but if it be pruned new branches are formed to supply those removed, but they are formed only at the expense of the fruit. Most of the dwarf apple trees (now fifteen years old) used in these experiments seem to have reached this stage; hard pruning in their case now results in an increase of the new wood formed, though the reverse was the case when they were younger, but the crops are still reduced by the pruning, and even more so than in former years.

What applies to a tree which has passed the age of active growth, and has reached maturity, applies also to a tree which has become stunted, or has had its growth arrested by root-injury, as, for instance, when it has been transplanted. The deficiency of vigour of a freshly planted tree is shown by the small size of the leaves and the tendency to form fruit-buds instead of wood. The correction for fruiting is, as has been shown, hard pruning, and it is, therefore, most important that freshly planted trees should be cut back hard so as to prevent precocious fruiting, which would generally result in permanent stunting. To delay this cutting back until the end of the first season would appear to be a very wrong procedure. It has been found that with trees which were not cut back, the size of the leaf was, on the average, 24 per cent. less, and the new wood formed 45 per cent. less, than with similar trees which were cut back; such vigour as the tree possessed went to form fruit-buds, which, when the cutting back was eventually performed, were removed altogether, or suppressed in favour of growth. A year's growth is practically lost by thus deferring the cutting back, and the ultimate result was found to be that the trees thus treated continued to form wood in subsequent years, whilst those which had been cut back at once were fruiting, so that the crop borne by them during the first ten years was only one-third of that borne by the latter.

Experiments on apples, pears, and plums show that the date of cutting back a freshly planted tree is immaterial so long as it is done before growth begins, that is, before about the middle of April. If delayed until the middle of July, the season's growth is much reduced, and the tree will probably suffer in subsequent years. This point was investigated more fully in the corresponding case of the hard cutting back or lopping, of older trees (plums), which had become slightly stunted. The operation increased the amount of new wood formed by the tree, and the results were the same so long as the lopping was done during the dormant season. Lopping towards the end of May resulted in less growth during the year, but this was more than compensated by an additional growth during the succeeding season. It is doubtful, however, whether anything is really gained by anticipating the autumn lopping (as is sometimes possible), and doing it in the preceding early summer, for it was found that the trees thus treated did not appear to be so healthy in foliage as those which were cut back subsequently. This was especially so where the cutting back was postponed until July, for trees cut back then made very little growth during the remainder of that season, and were deficient in growth in the following season as well.

Apart from the cutting back of freshly planted trees, the present results are emphatic in showing that the less pruning is done the better. But this does not imply that no pruning at all should be done. The removal of branches which cross or rub each other, as well as that of any unripened wood, is evidently desirable, and no doubt a certain amount of pruning, in order to obtain a compact and shapely tree, should be done during the first few years after planting. But a tree which is growing freely, and is properly tended in other respects, will require very little pruning to keep it in shape. With precocious or weak-growing varieties more pruning will be necessary, and more is required with standards than with dwarfs, for in the former case it is very desirable that a compact head and strong stem should be obtained before any heavy crops are borne.

STANDARDS AND EXACT MEASUREMENT

THE inaugural address delivered by Dr. R. T. Glazebrook, president of the Institution of Electrical Engineers—the full text of which is published in the current number of the Journal of the society (vol. xxxviii., No. 181, p. 4)—is likely to be remembered as one which stands apart among the various addresses which have been delivered in past years, owing to the fact that the subject treated is so rarely discussed or dealt with in ordinary engineering papers.

The subject in question, that of standards and exact measurement, is one which does not appeal to all, but is of special interest at the present time, when so much has been done of late by the Engineering Standards Committee to bring about more efficient work and more uniform results in the various branches of engineering. Dr. Glazebrook, in opening his address, gave a brief account of the history of standardisation from the first report of the Electrical Standards Committee of the British Association in 1862 down to the present day. This first

early report summed up the entire connection between the various units as follows —

"A battery or rheomotor of unit electromotive force will generate a current of unit strength in a circuit of unit resistance and in the unit of time will convey a unit quantity of electricity through the circuit and do a unit of work or its equivalent"

Mr. Duddell's report on the proceedings at the St Louis Conference brought up the question of electrical standards in its present-day phase Mr Duddell referred to two important resolutions passed at St Louis, and the question of giving effect to these was considered Since then matters have progressed considerably, and a conference was held at Charlottenburg at which representatives from America, Austria, Belgium, France, Germany, and Great Britain were present, and the following resolution was adopted —

"In view of the fact that the laws of different countries in relation to electrical units are not in complete agreement, the conference holds it desirable that an official conference should be held in the course of a year with the object of bringing about this agreement"

The result of the above resolution is that a future conference will be held this year in London, when the question of the fundamental electric units will be brought up Only two electrical units will be chosen as fundamental ones, and these will in all probability be the international ohm, defined by the resistance of a column of mercury, and the international ampere, defined by the deposition of silver

The international volt will depend on the above two definitions Experiments have been going on in all countries since October last to determine with extreme accuracy the quantity of silver deposited in a given time and the best method of constructing practical standards having a resistance of one ohm, and these results will be considered at the conference to be held in London this autumn, when we may hope that definitions of the international ohm and ampere will be finally settled

Not only is it necessary that the fundamental units of electrical science should be the same throughout the world, but the conviction has grown stronger that the extension of this principle would be of enormous assistance to the welfare of nations in general, and consequently international standardisation has become of the greatest importance

At the St Louis Congress two years ago Colonel Crompton introduced this question, with the result that it was unanimously agreed that the cooperation of the technical societies should be secured in order that the questions of the standardisation of the nomenclature and ratings of electrical apparatus and machinery might be thoroughly discussed The Institution of Electrical Engineers appointed an executive committee for this purpose, and practically all the civilised nations of the world cooperated

In this way the International Electrotechnical Commission was formed, and the central offices are for the present in London, at the offices of the Institution of Electrical Engineers

The task before the commission is a large one as the nomenclature alone will probably occupy its attention for a considerable period if one may judge by the labour entailed in the work of the electrical committees of the Engineering Standards Committee, which have been sitting lately

Standardisation has its dangers as well as its advantages, and it is in the avoidance of the one and the utilisation of the other that the great difficulty attendant on the work of such a commission will consist It is to be hoped that a happy mean may be found, which, while reducing the number of types of machinery which the responsible consumer or the consulting engineer can order, will not stultify the inventive faculties of engineers towards future developments

Dr Glazebrook further gives details of the reports of the Engineering Standards Committee on the various sections of engineering work on which it has already reported, the reading of which is of the greatest interest The work appears to have been done in a way that is thorough and complete, and every endeavour has been made throughout to increase the facilities for obtaining greater output per machine and to reduce the multiplication of patterns

It is gratifying to know that the work is already bearing fruit, and the recommendations have been adopted by the Government Departments, Lloyd's Registry, the British Corporation, and several other registry societies in regard to ship and boiler specifications With regard to rails, the Railway Engineers' Association are adopting the standards, and with but few exceptions every new tramway system in this country and many in the colonies which are under construction are being provided with these standard rails It is estimated that the saving to the British manufacturer by standardisation of iron and steel sections alone will amount to some millions sterling and we do not think that this figure is exaggerated when we take into consideration the fact that the frequent changing of the rolls to produce in small quantities the many "special" sizes asked for would be done away with

Although dealing with an infinitesimal part of this vast subject, the address opens out a most important question which will have to be considered, not only by the various branches of the engineering profession, but by every Government that has the welfare of its nation in view Dr Glazebrook is to be heartily thanked for the clearness with which he has dealt with his subject, and there is no doubt that his presidential address to the Institution of Electrical Engineers will long be remembered by those who were fortunate enough to hear it J L M

THE INFLUENCE OF PARASITES ON THEIR HOSTS

SCIENCE of February 8 contains the report of an interesting and suggestive address on this subject delivered by Prof H B Ward before the Section of Biology of the American Association for the Advancement of Science at the New York meeting held in December last (For other presidential addresses see NATURE of February 7, p 352)

After certain preliminary remarks, Prof Ward mentioned that some parasites, such as the distome Heterophyes, found in the intestine of Egyptian fellahin, seem to have no appreciable effect on their hosts The African eye-worm (*Filaria loa*) except when it actually enters the sclerotic of the eye, affords another instance Many encysted worms likewise come under the same category

As a rule, single parasites leave no lasting effects on their hosts, it is rather the multiplication of parasites which should be dreaded The most serious effects occur when this multiplication takes place within the host On the other hand, when multiplication takes place during successive generations in other hosts it is unlikely that the parasites, when in the proper stage, will reach the original host in sufficient numbers to cause serious mischief The real danger lies in a multiple infection through the numerical increase which such a species often undergoes in the intermediate host, or within a limited external area, so that by the intake of a single object a swarm may be introduced

As a rule, the harm caused by a parasite bears some proportion to its size as compared with that of its host, when, however, parasites occupy positions in connective tissue or between muscular fibres they may be relatively harmless, no matter what their size

Some parasites cause harm in a mechanical manner by blocking, for instance, natural passages, or, as in the case of the Egyptian blood-fluke, by the ova entering the capillaries when serious trouble is bound to ensue Embryos, in the case of filariæ, may likewise infest the lymphatic vessels, to the great detriment of their host

The migrations of parasites, as when *Ascaris lumbricoides* passes along the natural gangways from the intestine to the liver, may also cause serious harm, as abscess of the latter organ But parasites do not always confine themselves to such natural lines of movement, they may drive

tunnels for themselves, when still more disastrous results may accrue The abrasion and destruction of surfaces and cells and the opening up of abnormal communications are not, it is urged, of such serious importance of themselves, it is rather the secondary results from such lesions that are to be feared, such, for example, as the admission of bacteria from the alimentary canal into the blood and tissues For it is held by many that the normal mucous surface is impenetrable by bacteria, and the germs of cholera and typhoid depend to some extent upon diminished resistance, functional or structural, for their entrance into the tissues

No one, for instance, doubts that Eberth's bacillus is the active agent of typhoid, but there is strong reason to believe that before it can give rise to the disease there must be lesion of the intestinal mucous membrane The very fact that out of numbers who drink contaminated water but comparatively few are infected is strong confirmation of this

Parasites are likewise the inducing cause of changes which lead to multiplication, or proliferation, of cells and tissue, this being the case with both protozoa and bacteria The most common morphological change in the host is, perhaps, the development of a cyst round the parasite An example of this is afforded in the case of pearls In the Ceylon pearl-oyster the production of the best pearls is due to one particular cestode larva which passes part of its existence in the mollusc itself

On the other hand, the attempt to attribute cancerous and other abnormal growths to the action of parasites does not appear to be supported by the available facts

As regards such proliferation of tissues as is undoubtedly due to parasitic action, Prof Ward advances the hypothesis that this may be largely owing to poison generated by the intruder An inert body like a grain of sand will not give rise to the formation of a cyst or at all events to the proliferation of tissue, and it is probable that pearls cannot be produced by such means Parasitic bodies, on the other hand, feed and excrete, and nothing is more probable than that the excreta are toxic

This however, is not all, for the supply of nutriment to the parasites—nutriment frequently consumed in a wasteful manner—inflicts a severe strain on the host in a large number of instances The drain on the resources of the latter is indeed, practically three fold, owing to the rapid growth of the parasite itself the production by the latter of a large amount of reserve material (glycogen), and the great reproductive activity of the unbidden guest

A curious phase of parasitic infection is the frequent loss of reproductive power in the host due in some instances to destruction of the genital organs themselves, but in others to secondary influences The tendency for one sex to acquire the sexual characteristics of the other is a marked feature in this parasitic castration

The destruction of tissue by parasites, as in the case of that of the liver by the liver-fluke although in one sense a mechanical injury, is really more than this As the substance removed by the liver fluke is replaced by connective tissue, a most important organ of the body becomes to a greater or less degree degenerate

Among the physiological effects of parasitic infection none is more remarkable than the power possessed by species living upon blood of secreting a substance which prevents the coagulation of that fluid In regard to what has been stated above as to the development of toxic elements by parasites, the hæmosporidia of malaria undergo development in the red blood-corpuscles, and when they break up into spores the corpuscles are destroyed, with the probable discharge of poison into the blood As many corpuscles break up at once, the effects are serious The trypanosomes of sleeping sickness probably have a very similar physiological effect The existence of a toxic principle affords also the most satisfactory explanation of the phenomena of the progressive, pernicious anæmia present in some cases of bothriocephalid infection Anæmic conditions are also produced by direct blood-suckers, such as leeches and fish-lice. There remain, however, other forms of anæmia, such as that due to infection by the fish-tapeworm *Dibothriocephalus latus*, the physiology of which cannot at present be satisfactorily explained

THE BELGIAN INTERNATIONAL BALLOON SERVICE.

THE investigation of the higher regions of the atmosphere by means of unmanned balloons, which has been carried on by some countries for several years, generally on the first Thursday in each month, has already revealed some important facts, among which may be mentioned the inversion of temperature at various heights and the determination of the direction of the flow of the upper air-currents over land and sea The success hitherto attained well repays the expenditure of time and money incurred, and gives good reason for hoping that the study of aggregate results may lead to the ultimate solution of the problem of the general circulation of the atmosphere

At the instigation of the aëronautical conference held in St Petersburg in August, 1904, the Belgian Meteorological Service has taken part in this important work since the end of March, 1906, and M Lancaster has sent us preliminary notes of the results of the monthly ascents from Uccle between April, 1906, and February, 1907, published in *Ciel et Terre*, and in a note to the Belgian Academy in November, 1906 We have previously referred to the ascents in April and May, but include the data in the following general summary

The balloons are of india-rubber, coupled in tandem, having generally diameters of 1900 mm and 1350 mm respectively, and are inflated with hydrogen gas The meteorograph is made by Bosch, of Strassburg, and consists of barometer (Bourdon tube), two metallic thermometers (Hergesell and Teisserenc de Bort's models), and hair hygrometer A full description of the apparatus is given in *Ciel et Terre* for May, 1906 In this paper the values quoted are from Dr Hergesell's thermometer The starting place of the balloons at Uccle is 100 metres above sea-level, and the ascents were made from about 7h to 7h 30m a m Greenwich time

General Results of the Ascents

Date	Wind	Temperature at starting	Lowest temperature recorded	Height	Direction in which balloons fell
1906		C	C	metres	
April 5	S	1 9	−57 2	13,500	S S E
May 3	S S W	12 1	−62 6	10,160	E N E
June 7	N E	13 7	−65 7	11,460	S S W
July 5	N E	16 6	−58 0	9,829	S
Aug 2	S S E	22 0	−59 8	13,764	E
Oct 4	Calm	11 9	−65 3	11,524	E S E
Nov 8	N N E	9 0	60 8	10 504	N W
Dec 6	S S W	0 8	−51 6	9,168	S S W
Jan 14	W S W	5 2	−70 2	12,361	S E
Feb 7	E S E	−6 7	62 0	15,346 and 17,073	S S E

The following details, not included in the above table, are of interest —

April —An inversion occurred between 14,000 metres and 15 000 metres

May —A large inversion occurred above 10,160 metres, at the maximum height, 16,970 metres, the temperature had risen to −42° 0 C Humidity fell to 18 per cent at 10 330 metres, during the descent

June —Above 11,460 metres an inversion occurred up to the greatest height, 15,690 metres, where the thermometer read −54° 5 C Humidity, 22 per cent, at 2520 metres

July —Inversion occurred between 9800 metres and the maximum height, 15,682 metres, where the thermometer read −50° 0 C, humidity, 19 per cent

August —At the maximum height, 18,835 metres, the temperature was −50° 3 C, between 13,800 metres and 18,000 metres there was an inversion in a layer about 4000 metres in depth

September —The meteorograph was broken by collision with buildings at starting

October.—An isothermal zone occurred at about 11,500 metres, and an inversion between 1900 metres and 2000 metres. The minimum humidity was exceptionally low, being 9 per cent. at 4640 metres, and at the highest point (13,971 metres) 13 per cent.

November.—At 12,798 metres the temperature was $-53^\circ \cdot 0$ C., an inversion commenced at about 10,500 metres.

December.—At the maximum height, 11,935 metres, the thermometer read $-31^\circ \cdot 1$ C. An isothermal zone commenced at about 6660 metres, and continued with some fluctuations, until the bursting of the balloon.

January.—The greatest height reached was about 16,545 metres, temperature, $-62^\circ \cdot 3$. An inversion commenced at about 12,360 metres. Humidity, 19 per cent. at about 13,000 metres during the descent.

February.—The minimum temperature ($-62^\circ \cdot 0$ C.) was also recorded at 13,994 metres during the descent. An isothermal zone occurred between 15,346 metres and 17,073 metres (temperature, $-62^\circ \cdot 0$ C.), an inversion then set in, at the maximum height (18,472 metres) the thermometer read $-57^\circ \cdot 5$ C.

These isolated observations confirm the general existence of a stratum of air having a considerable increase of temperature, usually between 10,000 metres and 15,000 metres, referred to by Prof. Hergesell, M. Teisserenc de Bort and others and the opinion that it constitutes a distinct current in the upper regions of the atmosphere.

TERRESTRIAL PHYSICS IN THE UNITED STATES.[1]

IN the first of the publications described in the footnote we have an investigation of the figure of the earth as determined by operations in the United States. The deflection of the vertical at each station due to all known topography within 4126 kilometres of the station has been computed. Least-square solutions, based on all the observations, were made (1) on the supposition that the earth is rigid, (2) solutions on the hypothesis of isostacy corresponding to three different assumed depths at which the isostacy is supposed complete, (3) a similar solution on the usual hypothesis, that there is no relation between the observed deflection and the topography.

The authors direct the attention to the "particular method of attack," first, of those whose chief interest is in the figure and size of the earth, secondly, of those who believe that the condition of isostacy exists, and thirdly, of those who may, for any reason, have positive belief that cannot be reconciled with the existence of isostacy, inviting an investigation of the methods used.

Isostacy is thus defined:—"The excess of material represented by that portion of the continent which is above sea-level will be compensated for by a defect of density in the underlying material," the ocean being regarded as a defect of mass, and the corresponding compensation as effected by an excess of density in the underlying material.

The conclusions reached have been:—

(1) For the United States, the equatorial radius of the earth is 6,378,283 metres, the polar semi-diameter, 6,356,868 metres, the reciprocal of flattening, 297.8.

(2) Extreme rigidity is far from the truth. Isostacy is a comparatively close approximation. The States are in the main "buoyed up, floated, because of deficient density."

The isostatic adjustment made use of in the report is simply $\delta h = -\delta_1 h_1$, where h is the height of the surface above sea-level, δ its density, h_1 the depth of compensation below sea-level, and δ_1 the defect of density, h_1 being assumed a constant for each of the solutions in (2). This assumption is, of course, a crude one, though it facilitates the calculations, but it is sufficient to bear out the main contention that isostacy must be taken account of in determining the figure of the earth, and that the hypothesis of rigidity is untenable.

In the second of the above publications Mr. Hayford gives a general summary of the results of the survey as regards isostacy. He tells us that the evidence shows clearly and decisively that complete isostatic compensation within a depth of seventy-one miles is near the truth. The main impression which he endeavours to make upon his audience is that the earth is "a failing structure." The idea that the permanence of continents is due to elastic expansion of all the underlying material, as viewed in the light of geodetic evidence, he regards as extremely absurd, "whereas the earth is apparently inelastic to a high degree, even near the surface, and is apparently failing continuously," as shown by the ready adjustment of the figure to the effects of denudation. The author attributes the diminution of density beneath elevated regions to chemical changes caused by increase of pressure, but there is no allusion in either of these publications to the theory due to Airy, and described in Clarke's "Geodesy," that elevated tracts are hydrostatically supported by a protuberance of the crust, dipping down into a denser medium below—a mode of isostatic compensation much in accordance with the compressed condition of most mountainous districts.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

IT is reported from Ottawa that the engineering building of McGill University, Montreal, was completely destroyed by fire on April 5, the loss thus involved amounting to 150,000*l*.

THE Carnegie Institute at Pittsburg is to be dedicated this afternoon, and the ceremonies in connection with the event will continue until Saturday, when honorary degrees will be conferred by the University of Pennsylvania on a number of the foreign visitors. The *Times* correspondent at New York states that the gift of 1,200,000*l*. for an additional endowment and building fund for the institute, announced by Mr. Carnegie last week, makes the total sum given by him for the institute and for technical schools in Pittsburg more than 3,400,000*l*., while the technical schools can draw on him for 1,400,000*l*. more as money is needed. Mr. Carnegie's total contributions to Pittsburg and Allegheny now amount to more than 6,400,000*l*. So far as is known his total donations for public purposes in America and Europe amount to the stupendous sum of 33,300,000*l*. Of this total 10,800,000*l*. have been given in the last four years.

THE *London University Gazette* announces several courses of lectures for advanced students of science by university teachers. Among these may be mentioned eight lectures on "The Ancestry of Angiosperms," by Miss Ethel Sargant, at University College, on Mondays, beginning on April 29. Nine lectures on "Psychological Research in Schools" will be given on Fridays, beginning on April 26, lectures i.–iii. and vii.–ix. will be given by Miss B. Edgell, lecture iv. by Dr. A. D. Waller, F.R.S., and lectures v. and vi. by Mrs. Reid. Four lectures on "The Pineal Sense Organs and Associated Structures in the Vertebrate Brain," by Prof. Arthur Dendy, on Tuesdays, beginning on May 7, in the physiology lecture theatre, King's College. Twenty lectures in protozoology at the Lister Institute, Chelsea, by Prof. E. A. Minchin, on Mondays, Wednesdays, and Fridays, beginning on Wednesday, May 1; each lecture will, when possible, be followed by exhibits of microscopic preparations illustrative of the subject of the lecture. Dr. W. N. Shaw will resume his lectures on dynamical meteorology on Monday, April 29, in the physics theatre, University College. The course will be continued on Fridays and Mondays until Friday, May 17, inclusive.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 13, 1906.—"Experiments on the Length of the Kathode Dark Space with Varying Current Densities and Pressures in Different Gases." By F. W. **Aston**. Communicated by Prof. J. H. Poynting, F.R.S.

This paper deals with experiments on the length of the "Crookes" dark space under steady currents in air, oxygen, nitrogen, and hydrogen, and its relation to pressure, current density and potential in a cylindrical glass discharge tube the electrodes of which are large aluminium discs closely fitting the tube. Under these conditions it is found that so long as the current is kept above a certain value, *i.e.* sufficient to cover the kathode with glow and to cause the complete disappearance of the positive light on the anode, the distance between the electrodes has quite a negligible effect upon the dimensions of the dark space, the current, and the potential. The current ceases abruptly, however, when the length of the dark space becomes the same as that distance; also the negative glow terminates sharply (in the case of oxygen amazingly so) over the greater part of its area at a plane exactly parallel to the kathode at a distance from it (D) accurately measurable by means of a simple sighting arrangement. In order to eliminate edge effects and to get a more exact measure of current density, the kathode used was in the form of a disc and guard-ring, that current passing through the disc only being measured. If P = pressure, c = current density, V = potential between electrodes, then very approximately

$$D=\frac{A}{P}+\frac{B}{\sqrt{c}} \qquad V=\frac{F\sqrt{c}}{P}+E,$$

A, B, F, and E being constants for a given gas, the last being very nearly the same as the accepted values of kathode fall with aluminium electrodes in the gas.

These empirical relations, together with other observations, led to the conclusion that *the dark space may be regarded as a region of positive electrification travelling towards the kathode, in which the total positive charge exactly balances the negative charge on the kathode.* The theoretical fall of potential across such a region in which the density of negative electrification is assumed negligible is shown to be $\left(\frac{8\pi c}{\lambda}\right)^{\frac{1}{2}}\frac{2}{3}D^{\frac{3}{2}}$, where λ is the velocity of a positive ion in a unit field and c is the density of the current carried by the positive ions, so that if the latter bear a constant relation to the whole current density passing through the tube, we should expect cPD^3V^{-2} to be a constant for any gas. This is found to be the case for all values of the dark space between 0.5 cm. and 2.0 cm. in the gases under investigation. From the values so obtained the velocities of positive ions at the very low pressures (of the order of 0.2 mm. mercury) employed are calculated, and shown to be of the order expected from the values at atmospheric pressure determined by Zeleny. The stream of positive ions may be strikingly shown by a rotatory mica mill mounted *inside* the dark space, which rotates violently in the *opposite* direction to the familiar ones designed to show the motion of kathode rays away from the electrode. Suggestions are put forward to account for the almost incredible "sharpness" of the edge of the negative glow in oxygen, the most remarkable phenomenon of the investigation.

Mineralogical Society, March 19.—Prof. H. A. Miers, F.R.S., president, in the chair.—The silver deposit of Sedgman lode in the Perran Mine, Cornwall: F. H. **Butler**. The lode runs through killas in an approximately north and south direction. The silver ore, consisting almost solely of cerargyrite, occurs in compact masses or finely disseminated in a gossany limonite. Splintery and ferruginous quartz, the "cab-course," is always a well-developed feature in the richest parts of the lode. The distribution of the cerargyrite, to the depth of 18 fathoms to which the mine has been worked, is roughly in accordance with the surface contour of the land, but segregations have also taken place along a series of lines running from above downwards. The source of the chlorine, the author suggests, might be sea water that has reached [illegible] regions.—The minerals of the Silvermines District, Co. Tipperary: A. **Russell**. The mines extend along an east and west line of fault in which Silurian, Old Red Sandstone, and Carboniferous rocks are brought into juxtaposition. Along its course in certain places mineralisation has taken place, resulting in contact lodes and metasomatic deposits. In the Ballygowan South mine is an interesting occurrence of hemimorphite, the only one of the kind known in the United Kingdom. The mineral is found in brilliant crystals lining cavities in limonite. The gossan also contains irregular masses of argentiferous galena, partially altered to cerrusite. At the Ballynoe mine, copper pyrites, galena, and barytes form a lode between walls of Silurian and Carboniferous limestone. At the Gortnadyne mine argentiferous tetrahedrite is found with copper pyrites and cerrusite ("cat-tooth ore"). An extensive series of old open workings of galena can be seen at the Shallee East mine.—Baddeleyite from Ceylon: G. S. **Blake** and G. F. Herbert **Smith**. Three brilliant crystals of the mineral were picked out from a number of specimens of the heavy minerals from the gem district of Ceylon which were sent to the Imperial Institute in 1905. Of the three crystals, one possessing only the prism zone was used for analysis, and found to contain nearly 99 per cent. of zirconia. On the other two crystals, one of which was a twin, were observed eleven forms, including one new one (210).—Zinciferous tennantite from the Binnenthal: R. H. **Solly** and G. T. **Prior**. Crystals of tennantite, one of which was a large cube, with faces deeply striated parallel to small tetrahedral faces, were found on analysis to contain nearly 8 per cent. of zinc.—Strüverite, a new mineral: F. **Zambonini** and G. T. **Prior**. This new mineral was found in detrital masses of pegmatite near Craveggia in N. Piedmont. Crystallographically it is very similar to rutile and tapiolite, with axial ratio $a:c = 0.6456$. Some of the crystals are elongated along the pyramid edge, and are probably twins similar to those of ilmenorutile. The mineral is black and opaque, and has a specific gravity of 5.59. It contains titanic acid, zirconia, oxide of iron, and niobic and tantalic acid. The result of analyses suggests the formula

$$3FeO(TaNb)_2O_5.4ZrO_2.9TiO_2,$$

which may be written as a mixture of the three molecules $Fe(TaNb)_2O_6$, $FeZr_2O_5$, and $TiTi_2O_6$ in the proportion of 1:2:3. Chemically it is very similar to ilmenorutile, but contains about 28 per cent. of ZrO_2 replacing part of the TiO_2.

Zoological Society, March 19.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Recently discovered subfossil Prosimiæ from Madagascar, and their affinities with extant lemurs and with the higher Primates: H. F. **Standing**. The remains were obtained in the muddy bed of a swamp formed by the blocking up of the river Mazy by a lava flow, at from a few inches to 3 feet or 4 feet below the surface. They consisted of a large number of skulls and limb-bones of lemurs and lemur-like animals. This great amount of material enabled the author to corroborate the view, previously put forward by Dr. Forsyth Major, that the extinct lemurs of Madagascar were, in many respects, intermediate between existing lemurs and monkeys, and to express his belief that the New World monkeys and the Lemuridæ, as well as the Malagasy Indrisinæ, had a common origin. He also stated his opinion that it was not possible to separate the Primates, as hitherto, into the two suborders Lemuroidea and Anthropoidea.—Animal parasites: Dr. L. W. **Sambon**. Three new species were described:—*Wellcomia mitchelli*, gen. et sp. nov., habitat, small intestine of *Pedetes caffer*; *Sparganum baxteri*, sp. n.? habitat, connective tissue of man; *Schistosomum mansoni*, sp. n., habitat, blood-vessels of man. Dr. Sambon also described five new Hæmogregarines discovered by Dr. C. G. Seligmann and himself in snakes.—A collection of mammals, the seventh of the series, made by Mr. C. H. B. Grant at Coguno, Inhambane, and presented to the National Museum by Mr. C. D. Rudd: Oldfield **Thomas** and R. C. **Wroughton**. The collection consisted of 212 specimens belonging to thirty-nine species, of which six were described as new.

Entomological Society, March 20.—Mr. C. O. Waterhouse, president, in the chair.—Dr. F. A. Dixey exhibited several species of Phrissura and Mylothris, illustrating the remarkable parallelism between different forms of the two genera, a correspondence believed by the exhibitor to have a mimetic significance, the mimicry being probably of the Müllerian kind.—The following papers were communicated:—Studies of the Tetriginæ in the Oxford Museum: J. L. Hancock.—A list of the Coleoptera of the Maltese Islands: M. Cameron, R.N., and A. Camana.—The life-history of *Spindasis lohita*, Horsf.: J. C. Kershaw.—The egg cases and early stages of some South China Cassididæ: J. C. Kershaw and F. Muir.—The life-history of *Tessaratoma papillosa*, Thunb., with notes on the stridulating organ and stink gland: F. Muir and J. C. Kershaw.—The vinegar fly (*Drosophila funebris*): E. E. Unwin.—The structure and life-history of the holly fly: Prof. L. C. Miall and I. H. Taylor.—Note on *Xanthorhoë ferrugata*, Clerck: L. Doncaster.

Chemical Society, March 21.—Sir Henry E. Roscoe, F.R.S., past-president, in the chair.—Synthesis of polypeptides: E. Fischer. Continuing his work on the synthesis of polypeptides, the author has prepared an octadecapeptide containing fifteen glycocoll and three *l*-leucine residues.—Organic derivatives of silicon, part iii., *dl*-benzylmethylethylpropylsilicane and experiments on the resolution of its sulphonic derivative: F. S. Kipping. *dl*-Benzylmethylethylpropylsilicane is sulphonated by sulphuric acid at about 130°, yielding a mixture of acids, of which two, benzylethylpropylsilicolsulphonic acid and *dl*-benzylmethylethylpropylsilicanesulphonic acid, were isolated in the form of their *l*-menthylamine salts.—The reduction of carbon dioxide to formaldehyde in aqueous solution: H. J. H. Fenton. By the action of metallic magnesium on an aqueous solution of carbon dioxide, recognisable quantities of formaldehyde can be obtained, and the amounts formed are considerably increased in the presence of weak bases.—The mechanism of the rusting of iron: G. T. Moody. An experiment was described and shown which proved that in the formation of iron rust the metal must actually first pass into solution, and hence confirmation is obtained of the view that an acid, *e.g.* carbonic acid, is an essential factor in the rusting of iron.—Influence of non-electrolytes and electrolytes on the solubility of sparingly soluble gases in water: The question of hydrates in solution: J. C. Philip. The influence of non-electrolytes and electrolytes on the solubility of gases may be interpreted by supposing (1) that the non-solute takes no part in the absorption, and (2) that hydration of the non-electrolyte or electrolyte may occur, and the solvent thus attached is no longer free to absorb the gas.—A new class of organo-metallic compounds. Preliminary notice: Trimethylplatinimethyl hydroxide and its salts: W. J. Pope and S. J. Peachey. The chlorides of iron, cobalt, nickel, ruthenium, rhodium, palladium, osmium, iridium, platinum, and gold react vigorously with magnesium methyl iodide; trimethylplatinimethyl iodide, the corresponding hydroxide nitrate, chloride, bromide, and cyanide have been prepared by this means.—Some compounds of guanidine with sugars, part i.: R. S. Morrell and A. E. Bellars.—The action of aluminium chloride on naphthalene. Formation of $\beta\beta$-dinaphthyl, tetranaphthyl, and tetramethylerythrene: Miss A. Homer.—Mercurous hyponitrite: P. C. Rây.—The decomposition of mercurous and silver hyponitrites by heat: P. C. Rây and A. C. Ganguli. From the results obtained the authors are of opinion that these salts have both an oxylic and imidic constitution.—Studies in optical superposition, part iii.: T. S. Patterson and J. Kaye. The results of observation of the rotation of *l*-menthyl diacetyl-*l*-tartrate, both in the homogeneous state and in solution in ethyl alcohol, benzene, and nitrobenzene, taken in conjunction with those previously published (Trans., 1905, lxxxvii., 33; 1906, lxxxix., 1884), furnish thoroughly valid evidence as to the untenability of van 't Hoff's assumption regarding optical superposition.—An extension of the benzoin synthesis: R. W. L. Clarke and A. Lapworth. Benzylideneaniline hydrocyanide condenses with carvone and with benzylideneacetophenone to form respectively phenylimino-β-benzoyldihydrocarvone and γ-cyano-α-benzoyl-γ-anilino-$\beta\gamma$-diphenylpropane.—Interaction of starch and carbon disulphide. Xanthogenic esters of starch: C. F. Cross, E. J. Bevan, and J. F. Briggs. Starch moistened with the disulphide and then treated with a sodium hydroxide solution is brought into the condition for quantitative reaction and conversion into the xanthogenic ester (sodium salt).—The estimation of small quantities of nitrogen peroxide: R. Robertson and S. S. Napper. The method depends on the changes observed in the characteristic absorption spectrum of nitrogen peroxide as its concentration in dilute mixtures is increased.—The evolution of nitrogen peroxide in the decomposition of guncotton: R. Robertson and S. S. Napper.—An isomeric change of dehydracetic acid: J. N. Collie and I. P. Hilditch. If sulphuric acid of about 85 per cent. instead of about 90 per cent. is allowed to act on dehydracetic acid, the yield of triacetic lactone is much diminished. The by-product formed is pyronecarboxylic acid,

$$\begin{array}{c} CH_3C - O - C\,CH_2CO_2H \\ \| \qquad\qquad \| \\ HC \;\; CO \;\; CH \end{array}$$

PARIS.

Academy of Sciences, March 25.—M. A. Chauveau in the chair.—The approximate theory of the flow over a vertical weir, with sharp edge, without lateral contraction and in a free sheet: J. Boussinesq. A further approximation of a formula arrived at in a previous paper. The results are in accord with the experimental figures of M. Bazin.—Contribution to the study of phosphorescence: Henri Becquerel. The images of two specimens of the same phosphorescent salt, one being at the ordinary temperature and the other at the temperature of liquid air, were thrown simultaneously on the slit of a spectroscope. The changes thus noted for several uranium salts in the phosphorescent spectra are given in detail. The increased sharpness of the bands at the lower temperature enabled the polarisation effects to be studied. Those salts of uranium which can be obtained in well-defined crystals, cooled to the temperature of liquid air and illuminated with violet light, show no change in the spectrum when the incident light is polarised, but a change in the spectrum is observed if a Nicol is interposed between the phosphorescent crystal and the spectroscope.—A generalisation of the movement of Ponsot: L. Lecornu.—The coefficient of resistance of air to be adopted in calculations regarding aeroplanes: F. Ferber.—Rotatory magnetic polarisation in the neighbourhood of absorption bands. The magnetic rotatory power of crystals at the temperature of liquid air: Jean Becquerel.—The theory of the radiation of incandescent mantles: M. Foix. It is shown that the sole function of the thorium oxide is to form a support for the cerium oxide.—The influence of the surrounding temperature on the luminous intensity of an incandescent electric lamp: F. Laporte and R. Jouaust. A theoretical investigation of the effect of increase of temperature on the luminous intensity of an electric lamp shows that for a rise of 100° C. in the temperature of the lamp an increase in the luminosity of 0.4 per cent. might be expected. Direct experiment showed that the light remained constant for a rise of 100° C., and as the experimental error was of the order of 1 per cent., this is in agreement with the theoretical figure.—The supplementary channelling of spectra produced by parallel gratings: Georges Meslin.—The function and the nature of the initial discharge in the electric spark: G. A. Hemsalech.—The formation of ammonia gas from its elements under the influence of the electric spark; the influence of pressure: F. Briner and E. Mettler. The concentration of ammonia gas formed by electric sparks in a closed vessel attains a limit of about 3 per cent. to 4 per cent. at the ordinary temperature. If, however, the reaction vessel has its lower end placed in liquid air, the ammonia is condensed as fast as it is formed, and the reaction becomes complete. Working in this way and starting with a mixture of nitrogen and hydrogen in the correct proportions a nearly total vacuum can be obtained in the apparatus. A curve is given showing the effect of pressure on the yield, a pressure of 100 mm. of mercury was found to be the most favourable, the yield being 0.17 gram of

ammonia per kilowatt hour.—The age of the calcareous strata in the neighbourhood of Athens: Const. A. **Ktenas**.

April 2.—M. A. Chauveau in the chair.—The calculation of the inferior contraction of the sheet flowing over a weir with sharp edge and moderate height, and fitted with a horizontal plate above: J. **Boussinesq**.—An extension of the summation method of M. Borel: A. **Buhl**.—The nature of the body extracted from certain rich alloys of nickel and tin: Em. **Vigouroux**. Following the methods described in a previous paper the substance NiSn has been isolated as a crystalline powder, showing brilliant facets under the microscope. It is non-magnetic, and has a density of 8.44, the density calculated from its composition on the assumption of no contraction being 7.03.—The influence of manganese salts on alcoholic fermentation: L. **Kayser** and H. **Marchand**. The increased yield in alcohol resulting from the addition of minute proportions of manganese salts has been shown in a previous paper. It is now shown that yeast thus treated preserves its acquired properties through several generations, and the practical applications of this fact are indicated.—Rectal gills in the larvæ of *Simulium damnosum*. The adaptation of a larva of Simulium to life in the streams of equatorial Africa: E. **Roubaud**.—The nephro-poietic activity of the blood and of the kidney in the course of the renal regenerations: P. **Carnot** and A. **Lelièvre**.—The evolution of carbon, water, and ash as a function of the age in plants: J. **Tribot**.—Some seismic constants deduced from the earthquake of April 4, 1904: E. **Oddone**.

DIARY OF SOCIETIES

THURSDAY, APRIL 11.

ROYAL INSTITUTION, at 3.—The Birth and Affinities of Crystals: Prof. Henry A. Miers, F.R.S.

MATHEMATICAL SOCIETY, at 5.30.—A Theorem in the Theory of Functions: Dr. H. F. Baker.

FRIDAY, APRIL 12.

ROYAL INSTITUTION, at 9.—Conservation of Historic Buildings and Frescoes: Prof. A. H. Church, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—An Engineer's Visit to Japan and Canada: R. W. Allen.

MALACOLOGICAL SOCIETY, at 8.—Notes on New Zealand Polyplacophora, with Descriptions of Five New Species: H. Suter.—Descriptions of New Mollusca from New Caledonia: G. B. Sowerby.—Some New Species of Drymæus from Peru, Mexico, &c.: S. I. Da Costa.—A New Species of Vallonia from India: G. K. Gude.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—*Continued discussion*:—Petrol Motor Omnibuses: W. Worby Beaumont.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Early and late Perseids: W. F. Denning.—Determinations of Personal Equation depending on Magnitude made with the Transit Circle and the Heliometer at the Royal Observatory, Cape of Good Hope: Sir D. Gill and S. S. Hough.—Determination of the Secular Perturbations of the Minor Planet Ceres, arising from the Actions of the Eight Major Planets: C. J. Merfield.—The Electric Arrangements of an Observatory: W. F. Cooke.—*Probable Papers*: The Perturbations of Halley's Comet: P. H. Cowell and A. C. D. Crommelin.—On the Value of the Solar Parallax from the Greenwich Photographs of Eros, 1899–1900: Royal Observatory, Greenwich (Communicated by the Astronomer Royal).

SATURDAY, APRIL 13.

ROYAL INSTITUTION, at 3.—Studies in Magnetism: Prof. Silvanus P. Thompson, F.R.S.

MONDAY, APRIL 15.

SOCIETY OF ARTS, at 8.—Detergents and Bleaching Agents used in Laundry Work: Prof. Herbert Jackson.

TUESDAY, APRIL 16.

ROYAL INSTITUTION, at 3.—Wings and Aëroplanes: Prof. G. H. Bryan, F.R.S.

SOCIETY OF ARTS, at 8.—Joinery and Furniture Making: A. Romney Green.

ROYAL STATISTICAL SOCIETY, at 5.

ANTHROPOLOGICAL INSTITUTE, at 8.15.—Note on some Palæolithic and Neolithic Implements from East Lincolnshire: S. H. Warren.—Exhibition of Flints from Cornwall: A. L. Lewis and S. H. Warren.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Pyrmont Bridge: P. Allan.—Swing Bridge over the River Avon at Bristol: W. H. B. Savile.

WEDNESDAY, APRIL 17.

GEOLOGICAL SOCIETY, at 8.—The Toadstones of Derbyshire, their Field Relations and Petrography: H. H. Arnold Bemrose.—Data bearing on the Age of Niagara Falls: Prof. J. W. W. Spencer.

ROYAL MICROSCOPICAL SOCIETY, at 8.—On the Podura Scale: E. M. Nelson.—Exhibition of Slides of Foraminifera: A. Earland.

SOCIETY OF ARTS, at 8.—Aërial Navigation: Major B. F. S. Baden Powell.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Phenomenal Rainfall in Suva, Fiji, August 8, 1906: R. I. Holmes.—Temperature around the British Islands in Relation to the Gulf Stream: R. Strachan.—Weather regarded as a Function of Climate: L. C. W. Bonacina.

THURSDAY, APRIL 18.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On Reciprocal Innervation of Antagonistic Muscles. Tenth Note: Prof. C. S. Sherrington, F.R.S.—Fatty Degeneration of the Blood: S. G. Shattock and L. S. Dudgeon.—(1) The Rate of the Assumption of Chloroform by the Blood during Anæsthesia; (2) Function of the Red Corpuscles in Chloroform Anæsthesia: G. A. Buckmaster and J. A. Gardner.—The Fermentation of Glucosides by Bacteria of the Typhoid-coli Group, and the Acquisition of New Fermenting Powers by *Bacillus Dysenteriae* and other Micro-organisms: F. W. Twort.

METEOROLOGICAL OPTICS

Meteorologische Optik By Prof J M. Pernter In three parts. Pp 558 (Vienna and Leipzig W. Braumüller, 1902–6)

THE subject of "meteorological optics" has scarcely yet reached recognition as a distinct branch of physical science, as one of which it were desirable that the phenomena should be systematically gathered together in order that the interaction of all the circumstances affecting any one group of appearances might be the more clearly appreciated The various matters which may be legitimately included under such a title have, individually, not failed of their full share of attention and discussion in the nature of the case they have from the earliest times been the subject of curious, though not always careful, observation and speculation, and of most of the phenomena an explanation, at any rate approximate, has already been satisfactorily given The cause of the blue of the sky and of the "twinkling" of the stars, the theory of mirage, of the rainbow, of halos and mock suns, of all these much has been written, and by many physicists of eminence, but an exhaustive classification of all the questions which fall within the domain of meteorological optics has perhaps hardly been attempted

From the optical side, the most complete account of the subject previously given is to be found in Mascart's "Traité d'Optique", but the accumulation of meteorological data has proceeded somewhat more rapidly of recent years, and it is to the meteorologist that we must look for the exact quantitative solution of many problems in which the optical theory has already been correctly indicated Prof Pernter has every qualification for the task which he has set himself, and as director of the Imperial Institution in Vienna for the study of meteorology and terrestrial magnetism he brings to his subject an acquaintance with meteorological data such as few can claim His book will rank as a classic of scientific literature, and is little likely to be superseded, within more than one generation, as the standard work on this branch of natural science

Prof Pernter explains that his work is based on lectures delivered during a period of ten years in the Universities of Innsbruck and Vienna It is, however, singularly free from the defects one is prepared to find in a volume so produced, it is neither too diffuse nor too exclusively technical, and while essentially scientific, in the strictest sense, in its aim of giving an exact numerical explanation of the phenomena recorded, it furnishes a descriptive account of the appearances dealt with, from the records of observations, old and new, which the least scientific reader can scarcely fail to find attractive

Of the contents of the four sections into which the subject is divided the author's own classification is the best guide The first section deals with the apparent forms of the vault of the sky and the phenomena connected therewith—over-estimation of the heights of mountains, the apparent variation in size of sun, moon, and constellations between horizon and zenith, &c In section ii are included all the phenomena which owe their origin to the gaseous constituents of the atmosphere, whether under normal or abnormal conditions—astronomical refraction depression of the horizon, mirage, the "Fata Morgana," and the scintillation of the stars In the third section are considered the effects due to the presence in the atmosphere of masses of particles the appearance of which is intermittent—clouds, whether of ice crystals or rain-drops, and here we find a full discussion of halos and parhelia, coronæ and rainbows The fourth section, which will be issued next autumn, will treat of the phenomena due to the existence in the atmosphere of very minute particles of whatever nature which are always present but which are especially numerous at certain times, as after volcanic eruptions The classification thus indicated is both natural and convenient, with but rare exceptions it brings together all those phenomena which are of similar origin, and therefore demand similar treatment

Of the first section it will suffice to say that Prof Pernter gives a very careful discussion of the apparent form of the "vault" of the sky, basing his numerical results especially on the observations of Reimann His conclusion is that the form is that of a segment of a circle, the arc of which subtends at the centre an angle of the order of 40° From this it follows that estimations of dimensions near the horizon and at higher altitudes will differ widely, a factor having important bearings, is already indicated, in regard to many every-day phenomena to which we may add the apparently oval form of halos and coronæ at low altitudes In his explanation or rather his suggestion, as to the direction in which an explanation must be sought, the author follows Gauss, who first made experiments to show that this subjective effect is mainly due to the normally upright position of the body, and to the abnormal, or at least unusual, procedure involved in raising the eyes from the horizon to the zenith It need hardly be added that there are many points here demanding further discussion

The second section passes from the consideration of the effects due to atmospheric refraction under normal conditions to a very full and interesting account of the various phenomena due to reflection and refraction when the density of successive layers of the atmosphere shows abnormal variations or when the density in any region is subject to rapid fluctuations Prof Pernter is perhaps here at his best For the descriptive portion of the work he has sought the most typical examples to be found in scientific literature, giving in the words of the actual observers the details the explanation of which he afterwards follows out as closely as possible from the most exact data obtainable relative to the variations of atmospheric density We may direct attention especially to the author's theory of cases of exceptional "visibility" of distant objects, apparent nearness and magnification His theory of the

different forms of mirage, whether due to reflection from above or below, or from the side, is essentially that given by Tait in his paper "On Mirage" in the Edinburgh Transactions. Of the "Fata Morgana," two specially interesting examples are cited from observations by Prof Boccara in 1900 and 1901, while of distortion due to abnormal atmospheric refraction the most striking cases are those seen by Arctowski, as quoted from the records of the Belgian Antarctic Expedition

The theory of the scintillation of the stars and planets, and of the analogous phenomena observed in the sun and moon when almost eclipsed, has aroused an exceptional amount of attention, and is here very fully considered Lord Rayleigh has discussed the matter in a paper on the theory of stellar scintillation, where the failure of the "interference" theory as propounded by Arago is made clear The various optical effects in which the phenomenon may be said to consist, the quivering and the fluctuations in intensity and colour, as well as the meteorological conditions, the extent and character of the atmospheric "striæ," with the best methods of observation and measurement, are most completely dealt with in the papers by Karl Exner in the *Sitzungsberichte* of the Vienna Academy of Sciences and elsewhere Prof Pernter accepts what he designates the Montigny-Exner theory as giving a complete and exact explanation of the whole phenomenon

The theory of halos, of parhelia and anthelia, and allied phenomena given in the third section of the book is founded on the classical work of Bravais "Sur les Halos," which dates from the middle of last century Though Prof Pernter speaks of this theory, elaborated by Galle and Bravais as giving an entirely satisfactory and in all main essentials complete explanation of the phenomena, he is yet able, with the greater mass of more exact records of observations at his command, and the more accurate knowledge as to the form and optical characteristics of ice-crystals—six plates of reproductions of photographs of various types of ice-crystals are given—to confirm or correct in many details the earlier theory The rarity of some of the appearances necessarily renders numerical confirmation difficult, and it may be well to note, for example, the desirability of further careful observations of the "schiefe Bogen von Lowitz," the lateral arcs tangential to the halo of 22°, and of the parhelia related to the halo of 46°, especially the colour effects when the sun is in the horizon The whole discussion is fully and clearly given, and is very suggestive of the possibilities of further meteorological research

The author next deals with the phenomena due to diffraction effects, whether seen directly by transmitted light or by reflection—coronæ, the "Glory" or "Brockengespenst," iridescence of the clouds, &c—with an exposition of the theory as developed by Fraunhofer, Verdet, and Exner, and based on Airy's development of an expression for the variation in light intensity in the diffraction image The volume concludes with a complete discussion of the rainbow. Prof Pernter follows the theory of Descartes to the point where its neglect of the consequences of diffraction leaves it inadequate to explain the phenomena, basing his subsequent development on the Airy "*rainbow-integral*" for the intensity of light in the neighbourhood of a caustic.

Prof Pernter suggests that, in a subject of which so much has been written in monograph, his work must necessarily be of the nature of a compilation. He expresses the hope, however, that it may perhaps claim to be more than a mere compilation No one who has read his work with any attention will be likely to question this claim Rather it may be taken as the model of what a standard treatise on a branch of physical science should be, written by one whose researches have done very much to remove difficulties and to lighten obscurities Dealing as it does with matters of absorbing interest, it is unquestionably a book to be read by everyone who takes an interest in the study of natural phenomena.

THE NEW EVOLUTION

Recent Progress in the Study of Variation, Heredity and Evolution By R H Lock Pp xv+299 (London John Murray, 1906) Price 7s 6d net

THE labours of a new school of biologists, ably represented in this country by a band of energetic workers at Cambridge of whom the author of the present book is not the least distinguished, have been of great service both direct and indirect to the study of evolutionary method It was perhaps to be expected that in the first flush of enthusiasm caused by the re-discovery of an important generalisation like Mendel's, judgments should be formed and statements made some of which may seem to pass the bounds of scientific caution, but signs are not wanting that a more restrained attitude is beginning to prevail, and it is a healthy symptom that the free use of the experimental method, rather than mere academic discussion, characterises the work of the new evolutionists

A noteworthy point in the biological movement of the day is the response that is being given in various quarters to the reasonable demand for quantitative treatment of the facts of variation, selection and heredity From the side both of the biometricians and of the Mendelians, statistical evidence is being accumulated and dealt with on a scale that might have satisfied Stanley Jevons himself It must be confessed that the pretensions of these two schools are at present more or less antagonistic to each other and to the convictions of orthodox Darwinians, it is certain, however, that the questions raised in the course of this three-cornered rivalry are of the greatest importance, and that nothing but good can come of their thorough discussion

The book before us gives an elementary but generally clear and skilful exposition of the present aspects of the evolutionary problem. It is the work of one whose sympathies are confessedly Mendelian and mutationist, but who shows a real desire to do justice to the views of opponents. Mr Lock's point of view is far removed from that of certain half-

instructed writers in the lay Press, according to whom natural selection is nothing but a discarded fashion of the mid-Victorian period, as obsolete to-day as the pork-pie hat and the crinoline But he is none the less a disbeliever in the Darwinian account of the origin of species

High as are the merits of Mr Lock as an expositor, there are points, as we think, on which his arguments must fail to carry conviction The phenomena of adaptation we hold to be of supreme importance in the interpretation of evolutionary process It is difficult to exaggerate the extent to which adjustment to the circumstances of life prevails in every department of organised nature This is a fact which the advocates of "mutation" do not fairly face Mr Lock is too candid not to admit that "organic beings on the whole are, as a general rule, very closely fitted for the conditions in which they have to pass their lives" But after adducing certain well-known instances of "animals having peculiar habits, and possessing at the same time special organs which render them well fitted for these habits and no others," he manages to convey the impression that such cases are not very common, and that, considered as evidence of the power of natural selection, the best of them are open to criticism Then, after a sketch of the theories of mimicry and protective resemblance, he adds that it is "uncertain whether this principle [of natural selection] can hold good as the true description of the origin of any sort of resemblance"

"Perhaps a still more serious criticism," he goes on to say, "of the methods of those who spend their time in seeking out or devising cases of adaptation has been made by Bateson, who points out the logical difficulty that we can never make any quantitative estimate of the amount of benefit or the reverse which any particular structure may afford to its possessor" Most biologists will allow that quantitative methods should be used wherever possible for the solution of the problem, and it is curious that Mr Lock should apparently not be aware that there are several instances in which this has been done We do not see where the "logical difficulty" lies, on the question of fact we regret to differ from Mr Bateson, if his opinion is here correctly stated

The underlying idea in all that Mr Lock has to say on the subject of adaptation by selection is the doctrine that specific differences arise by way of "mutation," or *de novo*, and not by the accumulation of continuous or "fluctuating" variations The position is ably argued, and the results of the laborious experiments of de Vries and of the remarkable work of Johannsen are brought to bear with the skilful touch of a genuine investigator who is personally conversant with the matter in hand, nor does Mr Lock's general attribute of fairness here desert him. A point, however, on which we should like to be satisfied is this the author asserts that "no one questions the validity of natural selection as a means of exterminating types which are unfitted for their environment", further, he thinks it at least probable that certain types have survived in consequence of their "fitness." But, since these latter types arose, as he would say, suddenly or discontinuously, how did it happen that they sprang into being in such exact harmony with their surroundings? Would Mr Lock have us fall back upon the theory of "directed variation," or, what comes to the same thing, Paley's view of "contrivance" by special creation? If it be replied that a well-adapted type must have arisen, not by one or more large mutations, but by a series of mutations both numerous and minute, we should wish to know how such mutations are to be distinguished from continuous variations To say, with de Vries, that selection of individual differences is powerless to raise permanently the mean of a species, seems perilously like begging the question As soon as the mean had been permanently raised, the result would be claimed as a mutation

We have space only for one further remark If Mr Lock will take his Aristotle again, and read, with its context, the passage he has quoted on p. 116, we think he will see that he has mistaken that philosopher's meaning, as, indeed, Darwin did before him

F. A D

NOTES ON WATER PLANTS

Biologische und morphologische Untersuchungen uber Wasser- und Sumpfgewächse Part ii By Prof Hugo Gluck Pp xvii+256 (Jena Gustav Fischer, 1906) Price 18 marks

THIS work forms the second instalment of the author's studies on water plants It deals chiefly with the European species and varieties of Utricularia, and, as was perhaps inevitable, one result has been to increase the number of the forms hitherto recognised as distinct A prominent feature of the book lies in the attention devoted to the so-called *Turions*, or propagation buds, which occur so frequently in aquatic phanerogams

Several other aquatic genera also are dealt with, *e g* Ceratophyllum, in which Prof Gluck finds a specialised form of shoot provided with anchoring leaves, much reduced in character, which serve to fix the plant in the mud These leaves differ from the ordinary foliage leaves in the absence of chlorophyll and in the almost complete suppression of the intercellular spaces so characteristic of the latter

The conclusions reached as to the morphological interpretation to be placed on the different parts of the Utricularia plants do not essentially differ from those drawn by Goebel about sixteen years ago as the result of an extensive series of investigations on tropical as well as on European species of this remarkable genus The special feature of interest attaching to them lies in the impossibility of establishing a consistent distinction between the stem and leaf in these plants One can pass into or be replaced by the other in the most irregular manner, and either of them may in turn be represented in position by one of the bladders that form so characteristic a feature of the genus As Prof Gluck remarks, the

morphological distinction so commonly insisted on as between axial and foliar structures is largely the result of preconceived views as to their essentially separate nature, or, as we would prefer to put it, of the general experience that they are distinguishable. But morphological differentiation is really not irrevocable. There are many ways in which the normal (hereditarily transmitted) form may be changed if the sequence of those internal chemical changes that determine the structure at any given time and in any given instance can be interfered with, and this consideration should put us on our guard against the introduction of transcendental ideas into our morphological conceptions.

In the lower plants, in which the sequence of structural change has remained less stereotyped, it is sometimes easy to control the course of development, and within limits, to induce considerable modifications in organisation. As an illustration we may recall the well-known case of the influence of light in determining the dorsiventrality of Marchantia. This plant produces lens-shaped brood bodies or gemmæ, and when these are allowed to germinate, the surface (whether upper or lower), which is illuminated, assumes the structure of the normally dorsal, the less, or non-illuminated surface that of the ventral aspect. The behaviour under experimental conditions of *Aneura ambrosioides*, another liverwort, may also be quoted. This plant forms beautiful tufts or sheets of pinnate thalli, spread over the surface of the wet rocks or banks on which it occurs. But by appropriate methods of cultivation the plants can be made to grow erect, and then the ends of some of the pinnæ turn downwards to grow and ramify in the soil. The change thus induced is not necessarily permanent, and a restoration of the normal environment at once causes further growth to advance along the previous lines. But the interest attaching to such an experiment is enhanced when it is known that there are other nearly allied species the response of which to the influence of the *ordinary* environment takes precisely that form assumed by *A. ambrosioides* as the result of the introduction of certain special conditions. Many other examples of a similar kind will occur to those who are familiar with the results of the so-called "experimental morphology."

In the higher plants a certain degree of latitude of organisation is generally recognised, but its limits do not, as a rule, exceed the chief morphological barriers. The genus Utricularia, however, stands out amongst the flowering plants as one that has pre-eminently broken loose from the trammels of hereditary tradition. The chain of events which in the vast majority of plants are linked together in a sequence so orderly that the final result—differentiation into stem and leaf—seems invested almost with the sanctity of a law of nature is here rudely interrupted. It is to this very circumstance that the Utricularias owe their great importance from the biological standpoint, and any contribution to our knowledge of the group is assured of an attentive reception.

A NEW ATLAS.

The M. P. Atlas. A Collection of Maps showing the Commercial and Political Interests of the British Isles and Empire throughout the World. Forty plates. (Edinburgh and London: W. and A. K. Johnston, Ltd., 1907.) Price 25s. net.

THIS atlas consists of a series of maps chiefly representing the British Empire. They are very clearly printed, and some of them are decidedly good specimens of cartography. The bathy-orographical map of the British Isles is particularly worthy of notice. It is beautifully clear, and in every way an excellent piece of work. The special feature of this map is the orographical colouring, the effect of vertical relief being obtained by means of a system of colour-tinting in shades of brown, the shades increasing in density with the elevation. The bathymetrical colouring is in shades of blue. As this is such an effective map, it is a pity the same scheme of colouring was not adopted for the other physical maps, as in comparison they, and particularly that of India, are much inferior productions.

Throughout the atlas there is, unfortunately, a lack of uniformity in the style and execution of the maps which detracts in no small degree from their artistic merit. The collection is composed of engraved and lithographed maps, and the contrast between the fineness of the former and the coarser work of the latter is in many instances very pronounced, more especially when examples of the two styles occur on the same sheet, as on Plate 36. This variety in the method of production and certain inconsistencies which are to be found in the maps make it quite obvious that they have not been drawn specially for this atlas, but collected from various sources. There would be nothing to say against this system of using the same maps for different atlases, provided, of course, that they have been completely revised and brought up to the date of publication. But there is a great objection to the inclusion of old, or only partially revised, maps in a new atlas, and there are not a few in the "M. P. Atlas."

Quite a large number of the maps have already appeared in other atlases published by Messrs. W. and A. K. Johnston, most of them in the well-known "Royal Atlas," and many require much more thorough revision to bring them up to the date on the title-page. For instance, on the map of Asia (Plate 20), the physical features are shown exactly as in the same map in an edition of the "Royal Atlas" published fourteen years ago, notwithstanding the considerable alterations and additions recent exploration has made necessary. Then, again, there are railways and political boundaries that require correction. With regard to the latter, attention may be directed to a discrepancy between the boundary of northern Nigeria as shown on the general map of Africa (Plate 29) and on the map of the West African colonies (Plate 34). But no doubt these matters will receive the publishers' attention in revising the atlas for a future edition.

The atlas contains, besides the frontispiece—a bathymetrical hemisphere with London as centre—fifty-three maps. There is a political map of the world in Mercator's projection, and four small world-maps on an equal-area projection showing productions and consumption of foodstuffs, rainfall, and postal delivery. This last map employs a novel method of showing by a system of colouring the number of days taken to convey letters, posted in London, to different parts of the globe where there is a postal service. Next follows a useful series of maps showing steamer routes, railways, and telegraphs. Europe is represented by one general map and fourteen physical, commercial, and political maps of the British Isles. Asia has eight maps, of which India takes up six, the others are a general map of the continent and one of Persia and Afghanistan. The number of maps given to Africa is disproportionally large. In addition to one general and five divisional maps, there are four of the British African colonies, while the Australasian colonies are comprised in three maps—a general map of Australia on two sheets, unfortunately on different scales and in entirely different styles, and a map of New Zealand. With regard to the American continent, there is no general map of Canada, only three fairly large-scale divisional maps, and general maps of North and South America, the latter on two sheets. There is also a map of the North American Transcontinental railways.

The atlas has no index, which much lessens its use as a work of reference.

SOME BOOKS ON CHEMICAL ANALYSIS

Notes on Qualitative Analysis, Concise and Explanatory. By H. J. H. Fenton. New edition, revised. Pp. vi+147. (Cambridge University Press, 1906.)

Church's Laboratory Guide. Revised and partly re-written by Prof. E. Kinch. Pp. xvi+349. (London: Gurney and Jackson, 1906.) Price 6s. 6d. net.

Inorganic Qualitative Chemical Analysis for Advanced Schools and Colleges. By W. S. Leavenworth. Pp. vi+153. (Easton, Pa.: Chemical Publishing Co.; London: Williams and Norgate, 1906.) Price 6s. 6d. net.

Outlines of Qualitative Chemical Analysis. By F. A. Gooch and P. E. Browning. Pp. vi+145. (New York: J. Wiley and Sons; London: Chapman and Hall, Ltd., 1906.) Price 5s. 6d. net.

Qualitative Analysis as a Laboratory Basis for the Study of General Inorganic Chemistry. By W. C. Morgan. Pp. xiv+351. (London: Macmillan and Co., Ltd., 1906.) Price 8s. net.

Smaller Chemical Analysis. By G. S. Newth. Pp. 147. (London: Longmans, Green and Co., 1906.) Price 2s.

DR. FENTON'S well-known "Notes on Qualitative Analysis" is a mine of closely-packed practical information which, as the title-page states, is concise and explanatory. A student who works through the book and remembers only half the tests described should be well charged with chemical facts. The ordinary equations are generally used, an equation in terms of the ionic hypothesis being occasionally brought under the notice of the student.

Church's well-known "Laboratory Guide," which has been revised and partly re-written by Mr. E. Kinch, is exactly what its name implies. It is a practical guide to students of agriculture who wish to apply their chemical knowledge to that subject only. It does not pretend to deal with theory, which is left to the lecture-room, and the explanatory part is therefore reduced to a minimum. The book contains a series of exercises on the preparation of simple substances, on qualitative analysis, and, finally, on quantitative analysis, which fills up more than half the book. The simpler preparations being completed, the student is introduced to superphosphates, soils, and manures. Blood and bones and various materials of agricultural interest are dealt with qualitatively and quantitatively. Thus the student is not allowed to feel that he is being caught in the toils of pure science which may lead him anywhere or nowhere; he is, as it were, kept in full view of the farm and in touch with its products. There is very much to be said for this method, provided the scientific foundations are carefully laid. As to the exercises themselves, they are evidently devised and described by an experienced hand.

The volume on "Inorganic Qualitative Analysis" by Mr. Leavenworth is very like other books on the same subject. The directions are clear, correct, and concise—if anything too concise, for the suggestion that a reaction in certain circumstances may fail, is rarely recorded. The more general use of equations and the discussion of theoretical points would have made the exercises more of an intellectual and less of a mechanical process.

Of a somewhat different stamp is the volume by Gooch and Browning. The subject is approached in a more philosophical spirit. The principle of mass action—the basis of all chemical change—is discussed in the introductory chapter. The reactions are expressed by equations, and the conditions affecting precipitation, &c., are carefully indicated. The student is thus made to feel that each step requires a little forethought, that each reagent can only be effective under properly chosen conditions—in short, his intelligence is appealed to. There are several unfamiliar methods introduced, such as the separation of manganese from cobalt, nickel and zinc by means of acetic acid, the use of potassium ferricyanide for distinguishing cobalt and nickel, and the use of amyl alcohol for separating strontium and calcium. The English reader is reminded that "Robin's egg blue," which describes the colour of the manganates, has reference to the American bird. Although the constitution of salts is described under the terms of basic and acidic ions, no attempt is made to develop the subject on Ostwald's "Scientific Foundations", but the usual equations are employed. The book is carefully written, well printed, substantially bound, and may be confidently recommended as quite one of the best of its kind.

The volume on "Qualitative Analysis," by Dr Morgan, is less a work for the beginner than for the student who has already acquired a certain familiarity with experimental chemistry It is, in fact, a comprehensive study of analysis from the theoretical side The author has not merely raised his cap to the new teaching and adopted the old, like some authors referred to in this notice, but has boldly plunged into the ionic hypothesis and consistently adhered to it The book is divided into sections, the first of which deals with general principles, such as mass action, equilibrium, reversible changes, and dissociation, the second section is devoted to reactions of the common elements, arranged according to the periodic system, and the third deals with systematic analysis It is simply and clearly written, although the American spelling and the alternate use of names and symbols in the text are a little confusing to the English reader Nevertheless, the book has a distinct character of its own, it is interesting and suggestive, and will fill a gap in chemical philosophic literature

Newth's "Smaller Chemical Analysis" is an abridged edition of the qualitative section of the "manual," and includes a few quantitative exercises The small edition possesses the characteristic features of the deservedly popular parent volume For the student who is not intending to become a chemist, but who is taking chemistry as an adjunct to other studies, this abridgment will give him a very good notion of analysis He will learn a little manipulation, the use of reagents, and the behaviour of the common metals and acids There is nothing that is really novel in the treatment of the subject A passing reference is made to ionic dissociation, but the theory is not actually applied The figures which are taken from the "manual" are excellent, with perhaps the exception of the drawing of the wash-bottle and blow-pipe, in which the operator's moustache seems to form an essential part of the apparatus

OUR BOOK SHELF

Animal Micrology Practical Exercises in Microscopical Methods By Dr Michael F Guyer Pp ix+240 (Chicago University of Chicago Press, London T. Fisher Unwin, 1906) Price 9s net.

THE term "micrology" has not received any general acceptance on this side of the Atlantic There seems to be no reason why the term "histology" should be displaced by this more modern word. Though, however, we may take exception to the title of the book, we are not disposed to regard other than favourably the work itself

The study of this book leads to some reflection as to the methods by which instruction in histology can most advantageously be given Manuals of instruction are perhaps generally written so as to act as a *complement* to the teacher's personal directions This book, however, will replace the teacher himself The directions given are so precise and simple as probably to be sufficient to furnish an effective guide to a student with practically no previous training in microscopic work The question is, however, whether there are not disadvantages in this method The defect seems to be that a student using such a book may not have enough scope for his ingenuity and resource It certainly fails to give much stimulus to a student's power in the elaboration of new methods. But as the book is intended by the author primarily for the beginner, and as probably most students using it will adopt it simply to assist them in acquiring a competent knowledge of histological methods without any intention of making use of them in later research, it must be stated that, so far as this objective is concerned, the book is worthy of the highest praise

The general arrangement of the work has no markedly novel features, but the expositions of the methods recommended are admirably clear. The smallest details of procedure are carefully marshalled; and the student is generally left without any opportunity of making a mistake But the instruction afforded is not simply telling the student how the methods are to be carried out, there are added, and this is one of the distinguishing features of the work, explanations of the possible reasons why occasionally failure may occur, and remedies for such failures The author hopes that three classes of workers may be benefited by its use The student in class or the independent individual worker will doubtless profit, but we hesitate to think that a book can be at the same time valuable as an instruction manual for elementary classes and as a general reference book for the teachers of those classes

The crucial test of the value of the work must necessarily consist in the actual experiment of using it in class We venture to think, however, that the volume will react to this test in a most successful manner

Elementare kosmische Betrachtungen über das Sonnensystem und Widerlegung der von Kant und Laplace aufgestellten Hypothesen über dessen Entwickelungsgeschichte By Prof Gustav Holzmüller Pp v+98 (Leipzig B G Teubner, 1906) Price 1 80 marks

THIS little book, in which is summarised the essential parts of a series of lectures given at various times, is another praiseworthy attempt to make the results of mathematical analysis available to those who have not received the necessary preliminary training How far the author has been successful in conveying precise information to this class it is difficult to judge As a rule, it would appear that those who do read such books do not stand in need of the elementary treatment offered, while those for whom the book is intended fail to grasp the nature of the demonstration The author discusses some of the ordinary dynamical problems connected with falling bodies, and also Kepler's laws, as resulting from the operation of a central force. He adds some remarks on perturbations and tidal phenomena, but these sections are necessarily of the most sketchy character There is a very good chapter on the present condition of the sun, written in a popular manner, and in which the author introduces some interesting topics, but here, as in other parts of the book, we would willingly have been spared the quotation of such big numbers, inserted, apparently, with the view of arresting attention Finally, Prof Holzmüller examines the data on which rests the acceptance of the nebular hypotheses as developed by Kant and Laplace We are not disposed to quarrel with his conclusions, which may be stated thus. The hypotheses set up by these philosophers to explain the development of the solar system are inadequate to explain the past history, and furnish unsatisfactory guides for the future They cannot be regarded as a contribution to exact science, but

rather as unhealthy accretions At the same time, the author, following Gauss, has failed to recognise the extreme diffidence with which Laplace put forward his hypothesis By many, the caution and reserve with which Laplace accompanied his suggestions will always be regarded as a model of good taste and evidence of a correct scientific attitude

The New Hygiene. By Elie Metchnikoff Pp viii + 104. (London William Heinemann, 1906) Price 2s. 6d

THIS little book contains the three Harben lectures delivered by Dr. Metchnikoff at the Royal Institute of Public Health last year, an appreciative preface being contributed by Prof Ray Lankester The "Hygiene of the Tissues" is the title of the first lecture, and in it the phenomenon of phagocytosis is discussed at some length, and since this fact is considered to be the principal means of defence of the body against the invasion of microorganisms, and since such drugs as alcohol, opium, and many others impede phagocytosis, it is concluded that their use should be avoided or limited in the treatment of disease, and certain substances such as blood serum and salt solution, which stimulate phagocytosis, employed in certain circumstances In the second lecture, on the hygiene of the alimentary canal, the evil effects of parasitic organisms are dealt with and the use is advocated of sterile food so far as is possible The third lecture deals with hygienic measures against syphilis, and the use of inunction of mercurial ointment as a prophylactic against infection detailed. The book is of extreme interest and one that should be widely read by the educated public

R T H

Synopsis of Mineral Characters Alphabetically arranged for Laboratory and Field Use By Ralph W Richards Pp v+97 (New York John Wiley and Sons, London Chapman and Hall, Ltd, 1907) Price 5s 6d net

THE title of this convenient pocket-book serves to define its scope Emphasis is laid upon crystal form, habit, system, cleavage, hardness, fusion, and solubility in hydrochloric or other acid Definitions of mineral terms and of rocks associated with the minerals included are also provided The arrangement of the matter makes reference to the book easy

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications]*

Anomalous Dispersion and Ionisation

MY criticism of Mr Schott's interesting experiment (NATURE, March 14, p 461) was due to my carelessness in reading his brief account I failed to notice the words "and the tube" in his description of the battery connections, which fact, together with the low voltages which he used, gave me the impression that he employed the current to heat the wire, the ions being derived from the hot metal

The experiment as actually performed is of considerable interest Everything depends upon just what is meant by "the dispersion is completely annulled" I infer that the oppositely curved branches of the spectrum move back into the original straight line, but nothing is said as to whether the gap caused by absorption is filled in The dispersing power of the sodium tube depends upon the density gradient of the sodium vapour, as we pass from the floor to the roof of the tube Anything which interferes with this will alter the dispersion If the discharge stirs up the vapour and renders it homogeneous over each cross-section of the tube, the dispersion will be annulled, while the absorption will remain The nature of the action going on in the tube can probably be learned by looking through the tube at a bright sodium flame, or a gas flame provided with a blue screen which transmits only the region 4600–4900 It will be found that the upper portion of the tube is fairly transparent to the radiations, while the vapour along the floor is quite opaque to them. The effect of the current on the transparency at different levels should be noted

There has always appeared to me to be some mystery about the behaviour of sodium vapour in highly exhausted tubes for it is difficult to see how equilibrium can exist between the dense vapour along the floor and the nearly perfect vacuum along the roof In the light of recent experiments which I have been making, I now believe that I have found the solution of the apparent difficulty The actual density of the vapour along the floor has in all probability been over-estimated It is usual to exhaust the tubes to a pressure of a millimetre or two In all probability, pure sodium vapour at two millimetres pressure is what we should call a very dense vapour (considered optically) Suppose, now, we heat the floor of the tube to the temperature at which the vapour pressure of sodium is equal to the pressure of the residual gas in the tube The density of the sodium vapour considered alone (partial pressure) will depend upon the rate at which it can diffuse through the residual gas to the cooler roof of the tube If the sodium vapour is given off from the molten metal more rapidly than it can diffuse away we may have pure sodium vapour at the surface of the metal, and mixtures of sodium and hydrogen in decreasing proportion as we pass upwards towards the roof, the total pressure being the same at every point however If this is the true state of things, the dispersing power of the tube would disappear if every trace of the residual gas was removed I intend shortly to test this point I have already found that in the long steel tubes such as are used in observing the magnetic rotation of the vapour, the density of the sodium vapour is greatly increased by the admission of hydrogen or air In this case the central portion of the tube is uniformly heated with an electric oven and the sodium distils away to the cooler portions The presence of hydrogen or nitrogen hinders this process the gas holding back the sodium vapour, so to speak and allowing it to acquire a density or rather pressure equal to its own

This way of looking at the state of affairs in the tube may prove helpful in explaining the interesting effects observed by Mr Schott whose further experiments I shall follow with interest

Positive Streams in "Crookes" Tubes

REFERRING to the abstract of Mr F W Aston's very interesting paper read before the Royal Society on December 13, 1906, "On Experiments on the Length of the Kathode Dark Space with Varying Current Densities and Pressure in different Gases" published in your issue for April 11 (p 574), may I point out in reference to the therein contained statement that "the stream of positive ions may be strikingly shown by a rotatory mica mill mounted inside the dark space which rotates violently in the opposite direction to the familiar ones designed to show the motion of kathode rays away from the electrode," that in my two papers "On the Circulation of the Residual Gaseous Matter in a Crookes' Tube," read before the Physical Society, and published in the *Philosophical Magazine* for October 1898 I showed similar results, i e that mica mill wheels which turned in one direction under kathode ray bombardment, turned in the opposite direction when so placed as to be just outside of the stream of kathode rays thus indicating a current of particles proceeding towards the kathode, which particles I found to be charged positively?

These results, as stated in my first paper, could only be obtained with extremely high vacua, when no doubt the mica mill wheels were inside the dark space, as is found necessary by Mr Aston

TWO CONTRASTED WESTERN CANADIAN TRIBES[1]

MR HILL-TOUT'S volume fully maintains the standard established by its companions which have already appeared in the "Native Races of the British Empire" series, edited by Mr N W Thomas In clearness and lucidity it perhaps surpasses either of them, for, instead of numberless insufficiently known groups, such as those of Australia, or an inextricable mass of humanity such as crowds British Central Africa, it deals merely with two well-defined linguistic stocks, the Salish and the Déné, occupying clearly marked areas, and characterised by distinct ethnographic features Over the vast area between Hudson Bay and the Pacific Ocean diversity of climate has produced diversity of development, and the introductory chapter describes the geography, flora, and fauna of the region, and gives a brief history of the accounts of the early explorers before proceeding to the grouping of the native races

Rarely can two adjacent districts be found presenting greater physical contrasts than those on the two sides of the coast ranges To the east is the elevated plateau or "dry belt" with a temperature ranging from 110° in the shade in the summer to considerably below zero in the winter, while on the west the climate is like that of the south coast of Devon Beyond the Rocky Mountains extends as far as Hudson Bay a dreary plain of rocks, marshes lakes, and rivers, inclement and unattractive This naturally results in a marked differentiation in the mode of life of the coast Salish from that of the interior Salish, whereas the latter in this respect more resemble the Déné who live to the east of the Rocky Mountains It is interesting to note that among the western Déné, the Loucheux the social divisions seem to owe their origin to an economic variation They are divided into three exogamic divisions or phratries, called respectively Fish people, *Chit-sangh* (=fair), the Animal people, *Nah-t'singh* (=dark), and the Bird people *Tain-gees-ah-tsah* (middle or half-brightish) This seems to be a colour grouping The *Chit-sangh* are very fair in some instances approaching to white, and live largely on fish, the *Nah-t'-singh* live entirely on the flesh of the reindeer, and are very dark-skinned compared with the *Chit-sangh*, while the *Tain-gees-ah-tsah* live on salmon trout and moose-meat, and are neither so fair as the *Chit-sangh* nor so dark as the *Nah-t'-singh*

In spite of local diversity, both Salish and Déné show the "Pan-American" facial features, which are common throughout the whole continent together with a secondary type, approximating to the so-called Mongoloid type, but no other than facial resemblances seem to the author to be common to the whole race

Among psychic characters, the most striking are cowardice and honesty "In point of valour they fall far below the eastern tribes" "The Northern Déné are generally pusillanimous, timid and cowardly," but they are proverbial for their honesty and their hospitality and were in pre-trading days also for their chastity Their folk-tales and tribal traditions

"show us that their lives were moral and well regulated; that deep shame and disgrace followed a lapse from virtue in the married and unmarried of both sexes The praise and enjoyment of virtue, self-discipline and abstinence in young men is no less clearly brought out; whilst respect and consideration paid by the young everywhere to their elders affords an example that more advanced races might with profit copy"

The ethical principles of the Thompson Indians exhibit sound practical morality, and

"People who inculcate such virtues in the minds of their children can scarcely be called debased, or be said to be greatly in need of instruction from ourselves"

If they have fallen away from such high standards the fault is not theirs, but ours "We assumed a grave responsibility when we undertook to civilise these races"

Déné Maids in Native Costume From "British North America I The Far West"

All the main features of native life are well and succinctly described—houses, clothes, food, domestic and warlike implements, customs at birth, courtship, marriage and death, social organisation, and religious beliefs We wish, however, that the section on sociology had been more complete, but the most important omission is that of language, concerning which no information is given, although the author has elsewhere published a good deal on the linguistics of the Salish, on which subject he is an authority

The volume ends with an interesting summary, describing the ordinary life of an average native "From the Cradle to the Grave," a brief and valuable synthesis of the preceding material

"The life of an average Western Indian, as it was lived in the earlier days, was not that of a vicious

[1] "British North America I The Far West the Home of the Salish and Déné By C Hill Tout Pp xiv+263, with 33 full-page illustrations, and 1 map. (London Archibald Constable and Co, Ltd, 1907) Price 6s net

and degraded savage. He had advanced many stages beyond this when we first came into contact with him, and his life, though simple and rude, was on the whole well ordered and happy, and if his wants and aspirations were few, so were also his cares and worries"

The illustrations are numerous and very good, we are told on p 139 that hammers are commonly regarded by the uninformed as pestles, "but this is an error," yet in the description of the accompanying plate they are described as "pestles" and "hammers" It is greatly to be regretted that the utility of this book is restricted by the extremely inadequate "bibliography" (sic) The author's valuable papers in the Reports of the British Association, especially for the years 1899, 1900, and 1902, are not mentioned, neither does he give an exact reference to his own papers in the Journal of the Anthropological Institute No clue is given where can be found, to take only two examples Farrand's excellent paper on the basketry designs of the Salish Indians or the printed MS of Mr B R Ross The single allusion to Prof F Boas is to his work on skull-deformation (reference again omitted) and the series of British Association Reports ending in 1898 is not even mentioned, although the twelfth and final report, with a good index, is of exceptional value The important summary of Canadian ethnology in the Annual Archæological Report for 1905 (Toronto, 1906) contains papers by the author on the coastal Salish, and by Father Morrice on the Dénés, besides other valuable contributions by various authors, and as references are given to the literature the report serves as an admirable text-book on the anthropology of Canada It is strange that no allusion is made to this publication, at all events we recommend students who read Mr Hill-Tout's book to consult the report in order to supplement his deficiencies

THE LEICESTER MEETING OF THE BRITISH ASSOCIATION

THE British Association is assured of a hearty welcome to Leicester for its seventy-seventh annual meeting to be held there from July 31 to August 7, under the presidency of Sir David Gill, K C B, F R S Leicester is a place of great antiquity, few towns in England having a longer history of uninterrupted activity Its Roman remains include the "Jewry Wall," a remarkable example of brickwork, and some mosaic pavement *in situ* The geological features of the district are comprehensive, the Charnwood Forest, with its rocks providing many a geological puzzle, being within a few miles of the town Botanists, too, have a happy hunting-ground there The local committees and sub-committees are working hard to ensure the success of their efforts, and great interest is being shown on all sides in the visit of the association to Leicester A guarantee fund of more than 3300*l* has been raised towards the necessary expenses of the welcome, and this without any public appeal being made No less than eleven amounts of 100*l* and upwards are included in this sum

A call has been made on all the principal halls and public buildings throughout the town for general and sectional use, and it is believed that the arrangements when completed will be most satisfactory in every way The greatest difficulty the executive have had to meet has been the fact that Leicester possesses no town hall or public building large enough for the purposes of the holding of the usual conversazione and general reception of the large number of members and guests anticipated An ingenious suggestion, however, on the part of the chairman of the executive committee (Mr Alfred Colson), which has met with the full approval of all concerned, promises to overcome all obstacles, and even to make the proposed conversazione additionally attractive on account of the unique way in which it will be housed The intention is to utilise the whole of the present museum buildings, including the art gallery and mayoral reception rooms, for the use of which permission has been granted, and to erect on the four sides of the grass square adjoining a loggia or corridor constructed entirely of timber, 25 feet in width forming a covered promenade about 500 feet in length The four outer sides will be closed but the inner sides, overlooking the grass plot, will be open, and so constructed as to be easily beautified with floral decorations Internally the loggia will be draped with incombustible material and fitted with electric light and suitable furniture Besides answering for the reception to be given by the Leicester Literary and Philosophical Society the structure and grounds, with a military band in attendance will make a convenient general rendezvous throughout the week

A further edition of a very interesting work, "Glimpses of Ancient Leicester" by a local author Mrs Fielding Johnson is being issued in connection with this meeting and a handbook by another Leicester lady Mrs Nuttall will be provided The latter book will contain chapters on subjects of scientific interest prepared by various experts specially for the use of visitors

Excursions are being arranged to many points of interest in the district and the Mayor Alderman Sir Edward Wood J P will issue invitations to an evening *fete* in the Abbey Park Sir Samuel Faire J P will give a garden-party and it may be taken for granted that the social side of the meeting will be well provided for The comfort and enjoyment of all attending the meeting will not be overlooked, while the objects of the existence and visit of the association will throughout the week have the first consideration and thought

AN AERONAUTICAL EXHIBITION

THE well-arranged collection of balloon appliances and models of aeroplane systems organised by the Aero Club in connection with the Motor-car Exhibition in London presented a striking contrast to the want of organisation in the aeronautical section of the Milan exhibition of last year The large, almost empty room at Milan with no attempt at systematic display except in connection with the exhibits of the Prussian Government Meteorological Station, has no counterpart in the present exhibition Here everything was well displayed and there was no lack of exhibitors and assistants ready to give information to any inquirer

In studying the exhibits, I paid special attention to the aeroplane models, with the object of ascertaining how far they were likely to furnish material that would further the systematic study of the problem of stability and in particular of longitudinal stability which is the more difficult of study It appears both from theory and experiment, that a very slight change in the form or dimensions, or even in the velocity of propulsion of a model may change its motion from stable to unstable and that if one machine travels safely through the air, another very closely resembling it may overturn at once The general character of the exhibits does not seem to indicate that the constructors of flying models have

really grasped the all-important stability problem, or that the necessity of carefully studying the small oscillations of gliders, both stable and unstable, has been appreciated It seems probable that a great many constructors of would-be flying machines do not even know what is meant by a moment of inertia, yet both theory and experiment tend to show that the stability of a machine depends partly on its moment of inertia being neither too large nor too small

The models exhibited are of various sizes, and adapted for propulsion through the air by means of twisted elastics, like the familiar toys, they are however, of various dimensions, say from about 3 feet to 6 feet The trials which were made at the Alexandra Palace on Monday thus involved none of the dangers attendant on experiments with man-carrying machines It is to be hoped that some means were taken to record the actual motions of the models while in the air Such a record, if made in a way that would enable the positions and the velocities of the models to be plotted at every instant of the motion, could be made to furnish material the study of which will greatly advance our knowledge of the flight problem From what I learnt at the exhibition it appeared that this matter had not received much, if any, attention, but I was given to understand that two kinematographs would be employed to obtain the necessary records The necessity for two is obvious, and I can only hope that the requisite measurements of base line and angles were also attended to

In the following remarks I shall assume the result that a machine supported on aeroplanes has two kinds of longitudinal oscillations of different period, either of which may give rise to instability This is not generally known, but it is desirable to analyse the models even in the light of ideas which are to some extent anticipatory The rough notes taken are far from exhaustive, but they summarise a few points regarding some of the more conspicuous exhibits

Ezio Tani shows a most elegant and beautifully constructed mechanism in connection with the *motor*, the arrangement of wings does not *look* very practicable

Balston and Cochrane both exhibit propellers, &c, of corrugated aluminium

The *avroplane* looks a fairly practicable model The arrangement of two sets of planes tandem fashion appears suited for stability, at any rate so far as the short oscillation is concerned, but a great deal depends on whether the planes are parallel or inclined at a slight angle On the other hand, the increased moment of inertia caused by the projecting framework and the considerable distance between the front and hind surfaces may give trouble with the long-period oscillation

The Drexler model seems to go to the other extreme and suggests that the shortness of base may lead to trouble with the quick-period oscillation Here the planes are superposed, not arranged tandem

Weiss's *albatross* is really a model of a bird with curved wings How far this imitation of the shape of bird's wings conduces to stability cannot be completely studied without further experimental data than are at our disposal The model looks as if it would glide well for a short distance, but without a very careful system of recording, short flights teach us but little

Montford Kay shows a model of great length with propeller placed in the middle of a number of long parallel aeroplanes The arrangement seems ill-calculated for obtaining much lifting force from the air

Piffard shows a reasonable form of model with two pairs of superposed aerocurves, one behind the other As arranged at the exhibition, the combination looked as if it would be unstable for moderate velocities, but a slight change in the inclination of the aerocurves might make all the difference.

T W K Clark shows the most genuine attempt to cope with the problem of stability, he having followed the lines laid down by Chanute in the matter of flexible framework From what I could gather, however, the necessary movements for balancing were not arranged to take effect automatically, but the machine was a small-sized model of a type intended to be balanced and controlled by the dexterity of an aeronaut

It would be impossible from these rough observations to draw any very definite conclusions about the probable results of the competition, but it may be apposite to remark in conclusion that failures may teach quite as much as successes if only they are properly studied G H Bryan.

THE STUDY OF EARTHQUAKES

The Imperial Earthquake Investigation Committee of Japan has supplemented its well-known Publications by a bulletin, issued with the object of securing a quick publication of short notes and preliminary reports on seismological subjects. The series opens with a very interesting number; there are papers on the determination of the time of origin of a distant earthquake, on the methods of calculating the velocities of earthquake propagation, on the Tokyo records of the Calabrian earthquake, and, most interesting of all, a discussion of the cause of the San Francisco earthquake, by Prof Omori, who describes the great fault-fissure, referred to in Nature of June 21, 1906 (vol lxxiv), and notices that near Pt Arena and at some other places it did not show at the surface as a simple fault-fissure, but as a zone of distortion crossed by parallel shear-cracks, from the direction of which he concludes that, besides the relative displacement of the two sides of the fault zone, there was a general compression of the country from north to south This displacement was no mere surface phenomenon, as it appeared in the tunnel near Wright station, some forty miles S S E of San Francisco, at a depth of some 700 feet from the surface From the direction of overthrow of objects, Prof Omori concludes that the whole of the country along the fault has been displaced towards the N.N W, but the west side more than the east

In Austria the collection of earthquake statistics has been taken over from a committee of the Imperial Academy of Sciences by a newly extended Government Institute of Meteorology and Geodynamics The first of the seismological publications of this institute is a catalogue of the earthquakes of the Austrian Empire in 1904, which are detailed province by province with the addition of a general summary. A catalogue of this sort is as important and useful as a collection of meteorological tables, it is little more interesting to read, but, if not pleasant reading in itself, this little pamphlet suggests some interesting if not very comforting considerations. The science of seismology is essentially an English one, it is to Englishmen, and practically to two of them, that most of its fundamental concepts owe their origin, the ideas, which give vitality, and the terms which are in universal use, have almost all been born in this country, yet England remains without any permanent or official organisation for the collection of earthquake information, while one country after another is establishing a special service for this purpose Nor can the neglect be excused by

the plea that the British Government is not concerned in the subject as are those of Japan and Italy, for, if we are fortunately exempt from the visitation of seriously destructive earthquakes, this is not true of our possessions; moreover, as one of the principal suppliers of the materials which will be used in the building of earthquake-proof construction, we have a distinct national interest in earthquakes. In England, too, has been formed the most valuable organisation which exists for the study of those broader aspects of seismology in which the cooperation of widely separated observers is necessary; at more than fifty stations, scattered over the surface of the globe, instruments capable of recording distant earthquakes have been set up, and all report to one central station, where an abstract of their records is periodically published, but this organisation, which we owe to Prof. Milne, is entirely dependent on the energy and initiative of one man, it has no official status or permanent foundation, which will ensure its permanence or extension.

Meanwhile, Germany has been to the fore and instituted an International Seismological Association, which, not content with the holding of periodical meetings, on the model of the international congresses, has established a central bureau at Strassburg, where it aims at concentrating the study of earthquakes and the collection of seismological data. So far its activities have been largely devoted to the preparation of a catalogue of the earthquakes of the whole world, necessarily too incomplete to be of great scientific value, and to the collection, for the purpose of publication, of the seismograms of the Valparaiso earthquake, which, as has been shown in our pages, do not exist in that complete form, uncomplicated by the effect of other disturbances, which is necessary for scientific study. As aids to the advancement of science these count for very little, as advertisements they are invaluable, and in saying this we insinuate nothing against the founders of the International Seismological Association, we may acquit them of any commercial intention, we recognise the great services which its promoter has rendered to science, but the facts remain that, where the information is there will people go for advice, and where they go for advice there too will they obtain their materials, and so we are in a fair way to a repetition of the lesson of the Jena glass.

INDIAN ORCHIDS.[1]

ONE of the largest and most generally distributed of the natural families of Indian plants, the Orchids form at the same time a group in which considerable interest is taken by European residents in our eastern dependency. No order affords more satisfactory data where questions as to the distribution of species have to be dealt with or points connected with endemism require illustration. The value of such data increases as the records for particular areas approach completeness. In order that the records for at least one area might be made as nearly as possible exhaustive, Sir G. King planned, and with the help of Mr. R. Pantling, who made the necessary drawings, carried out a scheme for the description and delineation from fresh material of every orchid known to occur in Sikkim. The results were published in "Orchids of the Sikkim-Himalaya," which forms the eighth volume of the Calcutta Garden Annals.

The present work is, as Mr. Duthie explains, to be regarded as a supplement to that on the orchids of Sikkim. The area dealt with, which comprises the whole of the Himalaya to the west of Nepal, between 70° 30′ and 80° 40′ E., is no doubt much more extensive than the area investigated in the previous volume, which comprises only that part of the Himalaya which lies between Nepal and Bhutan, from 88° to 89° E. But though this be the case, the number of species to be dealt with is much smaller, only 173 orchids are known to occur in the whole north-western Himalaya, as compared with 449 in Sikkim alone, and of these 105 are common to both areas. The same thoroughness has, however, characterised the search for material, and the same care marks the description of the species, though some may regret that the scope of the work has not allowed of fuller criticism in certain places of the work of previous writers. The author has been especially fortunate in having at his disposal the services of a competent artist, Mr. Hormusji Deboo, who has prepared fifty-eight highly satisfactory figures of those species that are to be found in the north-western Himalaya, but that do not occur in Sikkim.

Apart from its value to systematic botanists and students of phytogeography, the work will be welcomed by residents in the hill stations of the north-west Himalaya as the previous volume has been by residents in Sikkim, who in their study of the orchids they meet with find themselves, particularly at first, unable fully to appreciate the characters and relationships of the species before them when they have to rely for information on technical descriptions, however excellent, that are unaccompanied by illustrations. Regret will perhaps be felt that so few plates have been given. It is true that figures of the other 105 species are to be found in the work on the orchids of Sikkim, and it will be realised that the editor of the Annals must have felt himself precluded from incurring the expenditure involved in figuring the same species a second time. Still the fact remains that the figures in the work on the Sikkim orchids, though good, fail to come up to the standard of the work of a trained draughtsman.

The author may be congratulated on the production of a memoir which sustains the character imparted to these Annals by the distinguished botanist who founded the series. The two ideals of scientific accuracy and practical utility aimed at in previous volumes, have been kept steadily in view, and the enlightened liberality of the Government of Bengal, which has rendered their publication possible, will be as gratefully recognised by botanical workers generally as it is by the editor of the Annals in the dedication of the volume before us.

[1] "The Orchids of the North Western Himalaya." By J. F. Duthie. Annals of the Royal Botanic Garden, Calcutta, vol. ix, part ii. Pp. ii+232; with 58 plates. (Calcutta: Bengal Secretariat Press, 1906.)

A RECENT ADVANCE IN THE KNOWLEDGE OF CANCER.

A COMPLETE presentation of the doctrine of the gametoid nature of malignant growths, and of the grounds upon which that doctrine rests, is contained in the first report on the cytological investigation of cancer, recently published.[1] The papers dealing with this subject have appeared in various publications, commencing with the original communication to the Royal Society by Farmer, Moore, and Walker in 1903, and they are here collected together and pre-

[1] University of Liverpool and Royal Infirmary Cancer Research Laboratories (Mrs. Sutton Timmis Memorial Fund). First Report on the Cytological Investigation of Cancer, 1906. By J. E. S. Moore and C. E. Walker. Pp. 87. (Liverpool: Published for the Liverpool Cancer Research Committee by the Priory Publishing Co., n.d.)

faced by an account of maiotic phenomena generally and a detailed comparison of those phenomena with the changes observed in cancer-cells

It will be remembered that the authors of the communication referred to drew a comparison between the nuclear phenomena in cancer-cells and those characterising the process of maturation in the cells of reproductive glands The degree of similarity between the two processes was found to be such as to suggest the inference that the type of cell-proliferation in the two cases was identical, and to those possessing a sense of the morphological significance of nuclear form this conclusion appeared to be warranted

Deviations from the normal mitotic process were, however, already well recognised in cancer-cells, and had been interpreted as being purely pathological phenomena Upon this view the resemblance between the nuclear forms met with in cancer-cells and those encountered in reproductive tissue would be regarded as accidental, and, in particular, the approximate halving of the number of chromosomes in individual cells of a group exhibiting extensive numerical variations both above and below that number would be looked upon as a merely chance occurrence

Before this interpretation could be considered to have been satisfactorily displaced, it was, therefore, necessary to demonstrate that the definite halving of the chromosomes occupies a dominant position in the cancerous process, and to trace in every detail the points of similarity between that process and the maiotic process of reproductive tissue Further research in these directions has tended to strengthen the original contention By constructing the frequency-curve of the numerical variations of chromosomes in cancer-cells the important position occupied by the definite halving of the number of chromosomes has been exhibited in a convincing manner, and the parallelism between the normal maiotic and the cancerous modes of cell division has been traced in such detail as, apparently to leave few points for further comparison

It may, then be confidently affirmed that the cancerous process has now been definitely and accurately referred to its physiological type, and, although the process may deviate from its type in certain particulars marked rather by degree than kind, such as the number of post-maiotic divisions, the validity of the assertion is not thereby affected, since the different circumstances in which the two processes arise must inevitably find expression in corresponding modifications in the processes themselves

A caution is given on p 25 against a too hasty assumption that all gametoid tumours are malignant It is well known that the malignancy of cancerous growths varies in degree in different cases, and that, as regards histological characters, every stage of transition may, in the case of certain organs more especially, be traced in different tumours between structures bearing the distinctive marks of malignancy and such as are undistinguishable from benign growths It is conceivable that at the limit of such a series of transitional forms, tumours may exist which, whilst possessing the features of gametoid growths, are devoid of the properties which denote malignancy The point is one of great theoretical interest, although in practice it is probable that such tumours would be treated as malignant in view of their close relationship to definitely malignant growths The authors however, barely touch upon this aspect of the subject, but suggestions are thrown out which appear to indicate further research into the nature of malignancy and a prospect of substantial results

NOTES

APPARENTLY, the British Government is indifferent to any increase of facilities for the advancement of knowledge, for it makes no attempt to show active interest in organisations and institutions concerned with science and higher education The Carnegie Institute at Pittsburg was dedicated last week in the presence of a large and distinguished company, but neither the British Ambassador nor any member of the British Embassy was present at the ceremony, though invitations were sent On the other hand, the German Emperor was represented by a special commission of six members of the highest rank, France and Italy were also represented, and there were present numerous representatives of other Embassies and Legations It is unfortunate that England should have been without a political representative upon such an occasion, but the omission is only another instance of the failure of British statesmen to understand the significance of anything relating to science or progressive learning The *Times* correspondent states that the absence of British representatives and the consequent tone of the whole proceedings left a regrettable impression among the British and Canadians, who formed a large majority of the foreign guests He remarks —" By Germany an opportunity has been cleverly and quite legitimately seized, by England it has been, by sheer stupidity carelessly neglected " These words could be applied to so many similar instances that they may be considered as describing the characteristic attitude shown by the two countries to scientific work We hope to give an account of the opening of the institute in an early issue.

PROF ROSS contributes a second letter to the *Times* of April 13 on the subject of Mr Haffkine's prophylactic and the Mulkowal disaster We are not so much concerned with the details of the case as with the broad questions suggested by recent occurrences in connection with the steps taken to prevent the spread of plague Prof Ross maintains that the whole story affords another signal instance of the disregard for science so frequently displayed in British administration and the evidence he offers establishes his position He states that in the nine years up to the end of 1905 more than 4,000,000 deaths from plague were recorded in India alone and Prof Simpson says that 20,000 deaths are still occurring there every week Though plague had been raging in Hong-kong for two years before the outbreak in Bombay, the authorities appear to have organised no system of sanitary intelligence, to have investigated few of the cases, and to have had no bacteriological department at hand The result was that when plague appeared all was confusion "No one seemed to understand," says Prof Ross, "that such epidemics can be successfully combated only by the methods which succeed in the case of a military invasion There was no scientific head of the defensive organisation, which was not even centralised until March, 1907. Generals and civilians were made dictators in a matter of which they had no knowledge, and occupied themselves with burning sulphur at street corners, and so on, and then, when these tactics failed, laid the blame on their subordinates, the doctors, whose advice they had frequently ignored and whose science they had habitually despised Everywhere, instead of the knowledge, organisation and discipline which are essential in such emergencies, we saw only nescience, confusion, and vacillation History shows that plague, if taken in time, can be quickly eradicated, and in my opinion the blame for this terrible visitation must be laid largely on those who governed the

country, but neglected until too late the precautions and organisation indicated by sanitary science" It is remarkable that our statesmen learn with such difficulty the value of the application of the methods of science to administrative matters, especially in view of the object-lessons provided by neighbouring nations, lessons sufficient to convince the least thoughtful of the use of science in deciding national difficulties It cannot be repeated too often, in the hope that eventually our legislators and administrators may learn the truth, that the nation which makes the most intelligent use of scientific discoveries and systematically approaches all questions in a scientific manner will assuredly occupy the most honoured place among the peoples of the world

THE Upsala commemoration of the Linnæus bicentenary will take place on May 23–25 The celebrations, which are to be held under the auspices of the University of Upsala, will begin on May 23, in the Aula of the University, with a formal reception of the guests On the evening of the same day a further reception will be held in the University buildings On May 24 there will be a promotion to degrees, only Swedish doctors being promoted It is proposed this year to revive the ancient custom of conferring degrees in the cathedral instead of in the University Aula The evening of May 24 will be taken up by a dinner given to the guests by the University and it is probable there will also be demonstrations on the part of the students On May 25 the Royal Academy of Sciences, Stockholm, will also commemorate the bicentenary in Stockholm All foreign delegates invited by the Upsala University will be provided with free hotel accommodation during their stay in Upsala and Stockholm

MAGNETOGRAPHS of Prof Watson's pattern have been installed recently in the Helwan Observatory near Cairo

MR F F BEDDARD, F R S, has been appointed an honorary member of the New Zealand Institute

M DESLANDRES has been elected president of the Astronomical Society of France for the year 1907–8

THE summer meeting of the British Archæological Association will be held this year in Dorset with Weymouth as the headquarters

THE Croonian lecture of the Royal Society will be delivered by Prof J B Farmer, F R S, on Thursday next, April 25 "On the Essential Constituents of the Nucleus and their Relation to the Organisation of the Individual"

A REUTER message from Mexico states that the towns of Chilpancingo and Chilapa in the State of Guerrero, have been destroyed by an earthquake

THE British Science League and the British Empire League will give a complimentary dinner to the Colonial Prime Ministers at the Whitehall Rooms on Thursday, May 2, at 8 p m

THE annual dinner of the Institution of Mining and Metallurgy will be held at the Hotel Cecil on Friday, May 3 Prof W Gowland, president of the institution, will occupy the chair, and many leading representatives of pure and applied science have accepted invitations to be present

ON Tuesday next, April 23, Prof W Stirling will deliver the first of a course of three lectures at the Royal Institution on "Stimulation, Luminous and Chemical" The Friday evening discourse on April 26 will be delivered by Mr J Swinburne, on "New Illuminants," and on May 3 by Sir James Crichton Browne, on "Dexterity and the Bend Sinister"

THE International Commission of Scientific Aerostation at its last meeting at Milan in October, 1906, resolved, on the recommendation of M Teisserenc de Bort, to carry on during the years 1907 and 1908 the investigation of the upper atmosphere in the northern hemisphere on a much more extended scale than has hitherto been attempted The Royal Meteorological Society has been invited to take part in this scheme, and the council proposes if possible, to organise and equip special stations in different parts of the British Empire north of the equator Unmanned "registering" balloons carrying self recording instruments, and also smaller "pilot" balloons, are to be used, the heights and drift of which will be determined by theodolites The ascents in 1907 are to be made on three consecutive days in each of the months July, September, and November

"BLACK rain" fell in Pembrokeshire on April 10 It was accompanied by a violent thunderstorm and a darkened atmosphere The ominous darkness was observed as far east as Cardiff, but the violent thunder, &c, was confined to districts further west Discoloured rain is also said to have fallen at Carmarthen There have been several such falls in South Wales of recent years One of these occurred round Barry, as well as in the west of England, on January 23 1902, and the matter was carefully discussed by Dr Mill before the Royal Meteorological Society A second fall took place on February 21, 1903 This was more extensive than the other, and the dust differed appreciably from that of the previous fall Analysis of the 1903 dust made at Cardiff College led to the belief that it was probably volcanic Traditional accounts of falls of frogs, snails, and fish occur in the annals of Glamorgan

THE *Daily Chronicle* of April 10 contained the following paragraph —"A thunderbolt fell at Birkenhead yesterday and several persons had narrow escapes from death When a storm seemed about to burst over the town a ball of fire swept over the Bidston Observatory, and struck a mound of earth, whence it rebounded into a field, and set fire to some gorse there A vanman who was near at the time was knocked down and a florist working in his garden was enveloped in a ring of flame and whirled several yards while the spade with which he was working was hurled over the hedge A cow grazing in a field was brought to the ground by the shock, and several workmen in the vicinity, who had trowels in their hands, were considerably alarmed at being knocked off the ladders on which they were working People who were several hundred yards away from the spot where the bolt fell received violent shocks, and were last night suffering from nervous prostration" Inquiries made at the Bidston Observatory with reference to the so-called "thunderbolt" and the amount of damage occasioned, show that there is little foundation for this somewhat sensational report Some of the features associated with the presence of "ball lightning" seem to have been noticed There does not seem to be any evidence that a globe of light was seen, but there were some signs of horizontal motion, and the characters of the after effects resemble those produced by this unexplained phenomenon But the essential mark of slow motion common to "ball lightning" was certainly not noticed and the injury to workmen at some distance though slight, points to the more ordinary effects of lightning

The injuries produced seem to be more nearly akin to those described as lightning strokes in the open field The irregularities of the surface of the land in the immediate district are very slight, and owing to the difficulty that lightning has in striking down upon a smooth plane surface, the boring of a hole in the ground some 2 feet in diameter and 18 inches deep has directed attention to this particular discharge by reason of its unusual character There was no evidence of fused silica near this hole

The Port Erin Biological Station has never been more fully used by workers in marine biology than during the present Easter vacation From the last week in March onwards throughout April, systematic collecting at sea and investigations in the laboratory have been actively pursued by as many biologists as can be comfortably accommodated During the first half of April ten to twelve investigators occupied seats in the laboratory and about the middle of the month a dozen senior students came in addition The researchers include Prof B Moore (biochemistry), Dr H Roaf (physiology of crustacea), Mr J Pearson (cancer), Mr R D Laurie (biometrics), Mr W J Dakin (Pecten), Prof Herdman, Mr Wollaston, and Mr Gunn, all from Liverpool University, Prof Hickson, Mr Chaffers, and Mr Whitnall, from the Victoria University of Manchester, Mr Unwin from the University of Leeds, and Mr Chadwick, the resident naturalist Plankton collections, both surface and deep, are being taken periodically, at stated localities, over a limited area for statistical purposes, from the S Y *Lady-bird*, and the usual sea-fish hatching and distribution of larval plaice is in progress

Dr B Glanvill Corney, chief medical officer of the Government of Fiji, directs our attention, in a letter received from Fiji, to an instance of poisoning by turtle's flesh which occurred at a village in the island of Vanua Levu, Fiji The turtle was cooked immediately after being killed, and no question of unfitness for food through putrescence arises, indeed, neither the history of its capture and preparation for the oven, nor of the symptoms which supervened after its ingestion, points in any way to poisoning by ptomaines The indications were, on the other hand, that the turtle itself had become poisoned before its capture, presumably through having consumed some unaccustomed article of diet on the reefs That something was wrong with the turtle before it was caught seems certain, as the men who captured it are reported to have discussed the question as to whether it was fit to be eaten Dr A W Campbell, district medical officer and magistrate of the locality near where the poisoning occurred reports the history of the attacks as follows — Severe headache and vomiting, abdominal pain, diarrhœa not marked So far as could be ascertained, in several cases an interval of seventy-two hours intervened between the ingestion of the turtle and the first symptom, and in most cases there was an interval of twenty-four hours Some four or five days after the attacks began, ulceration of the lips, tongue, cheeks, and fauces occurred, and every one of the cases seen was so affected Abdominal pain was not marked in the later stages Twenty-five deaths in all were attributed to poisoning by the turtle's flesh

The fourth part of vol v. of the Annals of the South African Museum contains a paper by Mr S Schenkling on new beetles of the family Cleridæ, and a second, by Mr P Cameron, on parasitic Hymenoptera

A definite mode of measuring the fossæ in the interior of the human skull forms the subject of a paper by Mr A Hrdlička, published as No 1521 of the Proceedings of the U S National Museum Such measurements are of considerable importance in estimating brain-volume, even in cases where the brain itself is available, the weight of that organ tending to alter the shape of its lower surfaces when removed from the skull

We have received copies of several parts of vol xvi of the Transactions of the Academy of Science of St. Louis, published at various dates during 1906 The first of these is devoted to an account of the celebration of the fiftieth anniversary of the first meeting of the academy. Land-snails from Michichan form the subject of a paper by Mr F C Baker, while Mr R J Terry describes the nasal skelton of the salamander *Amblystoma punctatum*, and Mr S Weller discusses the fauna of the Palæozoic Glen Park limestone

In their report for the year ending June, 1906, the trustees of the Australian Museum record their opinion that collections made in New South Wales ought not to be permitted to pass out of the country, especially when, by a simple process of combination amongst the State departments interested the collections in question could be acquired at a reasonable cost and subdivided amongst the various metropolitan and country museums It is also stated that until the museum is enlarged no further progress can be made in the exhibition of specimens to the public

Among the contents of part iii of the third volume of the quarterly issue of Smithsonian Miscellaneous Collections, reference may be made to a paper by Prof Theodore Gill on various non European representatives of the carp family (Cyprinidæ) One of the most remarkable features in the distribution of the group is the total absence of barbels (Barbus), which are so numerous and so widely spread in the Old World, from North America This feature, coupled with the peculiarities of the North American cyprinid fauna generally, is held by the author to afford a strong argument against the inclusion of the northern portions of the three northern continents in a single zoological region It is noteworthy, however, that an approximation to Old World types is met with among the cyprinid fauna of the Pacific slope of North America which is lacking in that of the opposite side of the continent

From a distributional point of view, great interest attaches to the description by Prof Al Mrázek, of Prague, in the *Sitzungsberichte der kgl Böhm Gesellschaft der Wissenschaften* for 1906 of a member of the group of flat-worms known as the Temnocephalidæ, from Montenegro These worms, which are parasitic on fresh-water crayfish and crabs, have hitherto been known only from tropical and subtropical countries, such as Australasia, Malaya, Madagascar, India, Chili, and Brazil, and the occurrence of an outlying form in the Palæarctic area is therefore very remarkable There are, however, other features in the fauna of Montenegro which indicate that it is of a somewhat abnormal type The host of the worm is the crustacean *Atyaëphyra desmaresti*, a species with a rather wide distribution in the south of Europe The locality where the worm was found is the delta of the river Morača, which discharges into the lake of Scutari, and on this ground the name *Scutariella didactyla* is proposed for the new form, which is regarded as generically distinct from Temnocephala. To the same issue Prof.

Meisek contributes an account of a polypharyngeal planarian from Montenegro, this being the second representative of that group from this country

No. 93 of the *Bulletin de l'Institut Océanographique*, published at Monaco, contains an illustrated account, by Mr. E L. Bouvier, of the Paris Museum, of zoological observations made during a cruise in the Atlantic in 1905 on the Prince of Monaco's yacht *Princess Alice* After briefly referring to the cetaceans and pelagic fishes observed, the author devotes considerable space to the invertebrate fauna of the Sargasso Sea, which he declares to be of surpassing interest to the naturalist Among the numerous species figured one of the most striking is a copepod crustacean (*Copilia vitrea*), in which the eyes are unusually large, while the swimming-limbs are richly garnished with feather-like expansions In the latter respect this crustacean presents a curious analogy to the well-known Sargasso fish *Antennarius marmoratus* Other Sargasso invertebrates, like a species of Sagitta, obtain protection by means of the pellucid nature of their tissues Considerable interest attaches to the observation that the hemipterous insects Halobates differ from all other pelagic forms in not seeking shelter below the surface in stormy weather A second chapter is devoted to the deep-sea fauna, among which the author directs special attention to the remarkable holothurian *Pelagothuria bouvieri*

THE *Irish Naturalist* for April contains the report of an address on the problems of an island fauna delivered by Mr. C B Moffat, as president, to the Dublin Naturalists' Field Club on January 8 Starting with the fact that the modern fauna of Ireland is poorer than that of Great Britain, and the latter inferior in richness to that of the Continent, the author raises the question whether the theory that this poverty is due to animals having been unable to effect an entrance into these areas affords a satisfactory solution The idea that oceanic islands have received their faunas by dispersive agencies is held to be untenable, such faunas it is argued, being merely remnants of larger ones derived from ancient continental connections On this hypothesis there would seem to be grounds for the belief that island faunas have an inherent tendency to self-effacement, and it is suggested that this tendency may be in part due to weakness in those members of a species which inhabit the peripheral zone of its distributional area "Both Great Britain and Ireland," it is urged, "certainly have lost, within times that were at least subsequent to the beginning of the ice-age, a considerable number of species, which are shown by the explorers of our caves to have flourished here when we had still a continental connection How they came to die out, we cannot say But I do think it is a mistake to assume that the insulation of the British and Irish areas has affected our fauna and flora in no other way than by preventing the advent of new species We have to explain how we have lost as well as how we have failed to gain "

IN an account, forming vol ii., No 1, of the Philippine Journal of Science, dealing with polypodiaceous ferns collected from one locality, San Ramon, on the Philippine island of Mindanao, Mr E B Copeland discusses their distribution in the different vegetative zones and their structural adaptations The collection amounted to the large number of 184 species, of which one-seventh were local and the rest Malayan In addition to the ecological notes that are very interesting but too detailed for summarising, the author has essayed the difficult task of formulating a taxonomic grouping of the order that is illustrated in a genealogical tree. Lastræa is regarded as a central type from which many branches, *e g* Microlepia, Polystichum, and Goniopteris, have sprung, Polypodium, Athyrium, and Acrophorus are associated with Lastræa as primitive forms

THE third number of the Kew Bulletin for the current year contains a list of flowering plants and cryptogams sent from Labrador by Sir William McGregor Special interest attached to the lichens, as it was suggested that an attempt would be made to naturalise the reindeer if the food material it requires was available in sufficient quantity According to the notes accompanying the specimens, *Cladonia rangiferina* appears to be abundant, and with it are commonly associated *Cetraria aculeata* and *Platysma nivalis* An article, "Alpine Notes from Sikkim," is extracted from a letter written by Mr I H. Burkill describing a tour in search of Aconite tubers, an illustration shows *Aconitum spicatum* and a hybrid Aconite in flower A new genus of Compositæ is defined from Tibetan material by Mr J R Drummond under the name of Chlamydites, having affinities with the Tibetan plant *Cremanthodium Deasyi* Two economic articles provide information on the distillation of camphor and the cultivation of ginseng, a variety of *Aralia quinquefolia*, in Korea.

IN the Journal of the Franklin Institute (vol clxiii, No 3) Prof Oscar C S Carter describes in detail the Government irrigation project at Yuma The project contemplates diversion of the waters of the Colorado River about ten miles north-east of Yuma, Arizona, into two canals In Arizona these canals will irrigate all the bottom lands of the Colorado and Gila rivers between the Laguna dam and the Mexican boundary, an area of 84 000 acres, and in California the bottom lands in the Yuma Indian Reservation an area of 17,000 acres Engineering skill of the highest order will be required The Roosevelt dam in the Salt River Cañon, Arizona, will be solid masonry 285 feet high and, joining the cañon walls several hundred feet apart, will form a lake twenty-five miles long and 200 feet deep The details given tend to show that the United States will soon take the lead as the foremost country where irrigation is practised on a large scale

THE Transactions of the Institution of Engineers and Shipbuilders in Scotland (vol l, part v) contain a suggestive paper on the mechanism of power transmission from electric motors, by Mr Wilfrid I Spence He brings forward possible alternatives to the commoner methods, with typical applications of each system Direct coupled drives are to be preferred to all others whenever practicable Belt drives are to be preferred to any form of strictly positive connection between constant speed motors and fly-wheel operated machinery A fly-wheel is quite useless with a constant speed motor positively connected to its load Single reduction spur gear may be regarded as the standard gear transmission for ratios up to 5 or 6 to 1 When the distance between centres is great, the idler spur gear (cast-iron pinion, raw hide idler, and cast-iron wheel) is a substitute for plain single reduction gear Chain gear may, as a rule, also be used, but only for ratios up to 5 or 6 to 1 For ratios up to 30 to 1, and where space is not of much account, double reduction spur gear is applicable As treble reduction spur gear, which is applicable for reduction between 40 and 150 to 1, takes up much space and is costly, it is not to be recommended When extreme compactness is desirable,

planetary gear drives may be used, and where silent running is desired with total enclosure, and a right-angled transmission is permissible, there is nothing to equal worm gear, which shows to best advantage for reductions of 15 or 20 to 1

We have received from Messrs Wratten and Wainwright specimens of their M screens and "Verichrome" and "Allochrome" plates for photomicrography, together with an explanatory booklet The screens, nine in number consist of gelatin films impregnated with dyes which admit the passage of light of certain wave-lengths, the values of which are given We have examined spectroscopically the light transmitted by each of them, and find it to be correctly stated in the booklet, which also contains a table of the absorption bands of the principal staining agents together with the proper screen and plate that should be used to photograph a specimen stained with any of the stains named The booklet contains a concise statement of the principles involved, of the method of combining the screens directions for tricolour work, exposure, developing &c The plates are undoubtedly some of the best for photomicrography that have yet been placed on the market, and the "Allochrome" plates will be found very useful in ordinary work by those who desire pictures of natural objects showing the proper gradations of light and shade A criticism which might be made is that the gelatin screens are somewhat delicate, being easily affected by damp and heat (it is true they may be obtained cemented between two glass plates, but are then much more costly) We have no hesitation in saying that Messrs Wratten and Wainwright have made a distinct advance, and have brought out their screens and plates on lines far more scientific than has hitherto been done

The London Geological Field Class has arranged its excursions for the study of the London district, under the direction of Prof H G Seeley F R S, to commence on Saturday, April 27 Mr J W Jarvis, St Mark's College Chelsea is the honorary secretary

The Halifax Education and Public Library Committee has arranged for the publication of a series of descriptive pamphlets on the more important objects in the Bankfield Museum under its care We have received a copy of the fourth of the series, sold to the public for one penny, which is on "Egyptian Tablets," and is written by Mr Thomas Midgley, curator of the Bolton Museums The tablets in the Halifax Museum were brought from Thebes to this country by Mr Jeremiah Rawson about 1839 They were built into the wall of one of the rooms of the Halifax Literary and Philosophical Society, and remained practically forgotten until eight years ago, when they were transferred to the Bankfield Museum, walled in, and covered with glass The pamphlet contains the result of Mr Midgley's work in deciphering the tablets The inscriptions all consist of prayers to various gods that funeral offerings of food drink, and so on may be given to the deceased in an after life Mr H Ling Roth, honorary curator of the museum, contributes a preface to the pamphlet

Mr Edward M Langley, of Bedford, writes announcing the discovery of an interesting contribution to the history of English mathematics in the form of a hitherto unpublished letter by the discoverer of "Taylor's theorem" The letter in question was addressed to the Rev Mr Newcome, fellow of St John's College, Cambridge, under date November 24, 1711 In alluding to the appointment of Saunderson to the Lucasian chair of mathematics at Cambridge, Brook Taylor expresses his opinions on the then prevailing spirit of mathematical teaching in the following words, which possess considerable interest in the light of modern thoughts on the subject The writer says —"I am very glad Mr Saunderson has it and hope he will fully answer the expectations the Electors have of him He is an extraordinary Algebraist, and I expect great Improvements in that Art from his hand, but (if I might have my desire) I would rather wish he would apply himself to the cultivation of Pure Geometry That is a large subject worthy of the labours of a Professor, and is abundantly more entertaining than the Contemplation of mere abstract quantities, which are the proper objects of Algebra, but that, truly speaking, is but an introduction to Mathematics as Logic is to Philosophy *And it is my opinion that the prevailing humour of treating Geometry so much in an Algebraical way has prevented many noble discoveries that might otherwise have been made by following the methods of the Ancient Geometricians*"

The report of the Hampstead Scientific Society for the year 1906 shows that the work of the society has continued in a uniformly satisfactory manner The society has been added to the list of "associated societies" of the British Association and is affiliated to the South-Eastern Union of Scientific Societies The Christmas juvenile lectures were successfully repeated, and a nature-study course for the benefit of those teaching young children was conducted by Mr W M Webb

The general report on the operations of the Survey of India during the survey year ending September 30, 1905, has now been published It was during the year with which the report deals that the Government of India appointed a committee to consider, among other matters, the state of the maps in each province and the measures required to bring them up to date This committee has since reported that in many parts of India the maps are so out of date as to be of little use, and in some cases even misleading, owing to changes in roads since they were prepared In order to carry out the recommendations of the committee it will be necessary to revise in the field practically the whole of the existing 1-inch maps of India, and to survey on either the 2-inch or the 1-inch scale the whole of the country for which maps on neither of these scales have ever yet been prepared Omitting the Baluchistan Agency and the tribal area of the North-West Frontier Provinces it is estimated that an area of 525,800 square miles of original survey will have to be re-surveyed, that a practical re-survey will have to be made of 479,000 square miles, while the maps of 266 300 square miles may be capable of revision in the field There remains an area of 266,300 square miles for which cadastral maps are or will be available from which to prepare topographical maps with inconsiderable corrections in the field, and 135,900 square miles, chiefly in Burma, for which the maps are modern, and merely require re-drawing It is proposed that the whole of this work should be carried out within twenty-five years while the survey of Baluchistan, the North West Frontier Province, and the country adjacent thereto should be completed within a much shorter period

The reviewer of the "Zoological Record" in last week's Nature (p 557) regrets to find that in the notice he omitted the second *n* in *Tyrrannosaurus* and *Tyrannosaurus*

OUR ASTRONOMICAL COLUMN

A New Comet (1907*b*).—A telegram from the Kiel Centralstelle announces the discovery of the second comet of the present year by Mr Mellish, at Madison, on April 14. The magnitude of the object is given as 11·0, and its position at 10h 20m (Madison M T) on the day of discovery was R A = 6h 40m, dec = +8° 0′

A second telegram from Kiel states that the comet was observed by Bianchi at Rome on April 16 Its position at 8h 22 1m (Rome M T) was

R A = 7h 0m 17 5s, dec = +17° 19′ 14″

This is about 2½° south of ζ Geminorum, and crosses the meridian at about 5 p m

A New Nebula.—Whilst searching for new double stars on January 18, the Rev T E Espin discovered a nebula in the constellation Perseus which he believes to have been previously unrecorded

This object precedes B D +33° 746 by 7·80s, and is 2′ 25″ south of it, so that it lies somewhere about halfway between ζ and ξ Persei It is about 6″ in diameter, and is elongated towards the north, its brightness being about equal to that of a tenth-magnitude star The later observations appear to suggest a planetary nebula with a small star on the northern edge (Monthly Notices R A S, vol lxvii, No 5, March)

Comet 1905 IV.—A further observation of comet 1905 IV (1906*b*) is recorded in No 4166 (April 5) of the *Astronomische Nachrichten* by Prof E Becker who, with the large refractor of the Strassburg Observatory, saw it as a small round body of about the tenth magnitude on March 4 The observations of this comet now cover a period of about 2½ years

In the same journal Prof Weiss gives a continuation of his ephemeris, extending from April 2 to June 5, which shows that the comet is apparently travelling very slowly through Libra in a north-westerly direction towards Virgo

The Temperature of Mars.—Hitherto the chief obstacle to the belief that Mars is habitable by any such beings as inhabit the earth has been the extremely low temperature probably obtaining on the Martian surface, but in No 25, vol xlii (March), of the Proceedings of the American Academy of Arts and Sciences, Prof Lowell shows that, by taking all the phenomena into consideration, this obstacle may be removed Previous calculations of the temperature have been deduced solely from the relative distance of Mars from the sun, and a recent investigation gave −33° F as the mean temperature of the planet

Prof Lowell points out, however, that other factors, such as the relative albedoes of the planets, the screening effect of clouds, the blanketing effect of the atmosphere, &c should be taken into account, and, on this basis he finds that the mean annual temperature of Mars, if the heat were retained as well there as here, would be about 72° F As the retention is greater in the case of the earth, this value is considerably reduced in the final calculation, taking all the known factors into consideration, and a mean temperature of about 47° F is obtained Prof Lowell also finds that the boiling point of water on Mars would be about 111° F (44° C), that the amount of air per unit surface is about two-ninths that found in the case of the earth whilst the relative density of the air at the surface is only about one-twelfth

Galileo in the Val D'Arno.—The April number of the *Monthly Review* contains an interesting article by Miss Janet Ross giving some details of Galileo's life whilst he dwelt near Florence, first as court mathematician and philosopher, then as a prisoner at the hands of the Inquisition It was at a villa known as "Le Selve," near Signa, that he discovered spots on the sun and wrote his treatise on the planets, his history of sun-spots and other works whilst in a second villa in the neighbourhood, now known as the "Villa dell' Ombrellino," he wrote the "Saggiatore" and commenced his "Dialogues on Motion" After the persecution at Rome in 1633 he lived at Il Gioello Arcetri, and it was here that the Inquisition forbade him to converse with anyone, so that from that date until his death in 1642 he was an isolated prisoner, and for the last four years was totally blind Miss Ross also gives some interesting facts concerning the philosopher's family affairs

Another New Astronomical Journal.—From the Società Astronomica Italiana we have received the first three numbers (January, February, and March) of its monthly bulletin, the *Revista di Astronomia e di Scienze affini* The society was founded by Prof Boccardi, of the Turin Observatory, in November, 1906, and has for its principal aim "the vulgarisation of astronomical conceptions" These bulletins contain original articles astronomical notes, and reviews, together with ephemerides and notes concerning celestial phenomena for the succeeding month, and are published by the society at Turin

The Stonyhurst College Observatory.—Father Sidgreaves's report of the work done at the Stonyhurst Observatory during 1906 contains, in addition to some astronomical notes the detailed results of the magnetic and meteorological observations made during the year On the astronomical side the sun was observed and drawings of the solar surface made on 212 days, and the large grating spectrometer was employed on the larger spots For this work a new heliostat is being built which will carry a 12-inch mirror, and when the instrument is complete it will be possible to employ the full aperture of an 8-inch objective for use with the large Rowland grating in solar spectroscopy Good spectrograms of Mira Ceti and some selected brighter stars were obtained during the year The mean magnetic declination for 1906 was 17° 48′ 3 W

THE TWENTIETH YEAR AT BLUE HILL OBSERVATORY[1]

Blue Hill Observatory on January 30, 1905, completed its twentieth year's work, and it is noteworthy that three out of its staff of four have been there at least eighteen years Owing to the crowds of people brought to the hill by the electric cars, it was found necessary in 1905 to enclose the observatory by wall and fence, some of the secondary instruments having previously been moved for the same reason Blue Hill is one of the few American observatories where the standard instruments have remained in the same position and with unchanged environments for so long a time so that except for the fact that the times of observation were changed to agree with those made by the U S Weather Bureau the records are all strictly comparable Since 1901 the observations have all been published in the metric units, English units being only used in parallel in the summaries

The exploration of the upper air by means of kites carrying instruments which recorded continuously was first originated at Blue Hill in 1894 In 1901 the first observations over the North Atlantic were made by the director, Mr A L Rotch, and Mr Sweetland, using kites flown from a steamer Kite observations are now made whenever possible on the days fixed by the International Committee for Scientific Aeronautics These are generally the first Thursday in each month In 1903 fifteen flights were made nine of these being on days fixed by the committee The average height reached was 2214 metres In 1904, eight out of fourteen flights made were on appointed days and the average height was 2300 metres In 1905, sixteen days were assigned by the International Committee and at Blue Hill flights were made on twelve of these and on four other days, the average height reached was 2120 metres During the three years the maximum height reached was 4468 metres, or 14 662 feet Since 1894, 280 flights have been made at Blue Hill

In September and December, 1904, and January 1905 at the St Louis Exhibition Assman balloons were liberated with instruments During the summer of 1905 another series of ascents was executed by Mr Fergusson Out of the thirty-five balloons liberated at St Louis thirty-two have been returned, most of them with records of pressure and temperature The records show that fifteen balloons

[1] Annals of the Astronomical Observatory of Harvard College Vol lviii, part ii Observations and investigations made at the Blue Hill Meteorological Observatory, Massachusetts, U S A, in the years 1903 and 1904

reached a height of more than 8000 metres (five miles) Two of them had travelled at a rate of 100 miles per hour The maximum height reached was 17,037 metres, or nearly eleven miles, and the lowest temperature recorded was $-79°$ C, at a height of 14,800 metres

While Mr Clayton was crossing the Atlantic to Gibraltar to join M Teisserenc de Bort and M Maurice on the cruise of the *Otaria*, he executed six kite flights, and on the cruise nineteen flights were made From the Azores, Madeira, and Canary and Cape Verde Islands twelve balloons were sent up, and records were obtained of the wind velocity and direction up to altitudes of 13,600 metres It was demonstrated that the upper return trade winds in the northern hemisphere blow generally from the south, and that the chief features of the vertical distribution of temperature and humidity were the differences between the east and west sides of the permanent anticyclone and the stratification of the atmosphere in the region of the trades and the doldrums (see NATURE, November 16, 1905, and March 8, 1906) These investigations are to be continued to see if the proximity of land influences the upper-air currents over the ocean

In the tables giving the records obtained by the flights in 1903 and 1904 at Blue Hill, the reading corresponding with the different altitudes of the kites, are all compared with simultaneous readings made in the observatory, and the initial and final readings on the meteorographs are compared also with those at the station at the base of the hill The height of the kite was determined from its angular height and the length of the wire, with a correction for sag When the kite was not visible, its height was determined from the corrected readings of the barograph it carried

In order to eliminate the effect of sluggishness of the instruments, the temperature readings were taken from the records at points which coincided with stationary points in the flight Humidity was recorded by means of a hair hygrometer, which had been standardised by comparison with a psychrometer before and after the flight The direction of the current in which the kite was flying was determined by the azimuth of the kite from the reel

During 1902 and 1903 a long series of observations was made to study the effect of meteorological conditions on atmospheric refraction From Blue Hill, Boston Lighthouse can be seen more than fourteen miles away, and the difference between the geodetic and observed dip of the line of sight observed three times a day W M

SCIENTIFIC WORK IN THE STRAITS SETTLEMENTS AND CEYLON

THE last number of the Journal of the Straits Branch of the Royal Asiatic Society is full of matter interesting to various classes of readers —for botanists, Mr H N Ridley's studies on the grasses, sedges, Scitamineæ, and Begonias of Borneo, for zoologists, Mr P Cameron's account of the Hymenoptera of Sarawak, for anthropologists, Mrs Bland's description of the curious Anyam Gila basketry of Malacca, and Mr Howell's Dyak ceremonies in pregnancy and childbirth, with a list of remarkable taboos imposed upon the woman before and after delivery, and, lastly, for folklorists several tales collected by Messrs Maxwell and Laidlaw The most important contribution to the number is Mr Ridley's article on the menagerie at the Botanic Gardens, Singapore This was started by a local society in 1859 taken over by the Government in 1874, and, finally, the valuable collection was dispersed in 1903 on the ground that the authorities could not afford funds for buildings and a modest annual grant for maintenance It is certainly a misfortune that this institution should have met such a fate As Mr Ridley points out, there are few places in the world better suited for a zoological garden than Singapore Maintenance charges are low, and the vicinity of the source of supply renders it possible to procure specimens at a small cost Mr Ridley gives valuable notes on the various genera, and supplies useful hints on the methods of keeping animals in captivity He lays down as a maxim that "the only way of knowing what an animal thinks is comfortable and snug is to keep it and observe its ways. It will soon let you know what it likes, which probably does not at all fall in with your ideas of what it ought to like" His notes on the habits of the larger Quadrumana are based on first-hand knowledge. A pair of Indian jackals, he tells us, bred in the gardens, which is, to say the least, unusual The Malay tapir (*Tapirus indicus*) displayed remarkable cryptic characters When in its young pelage it hid in a palm bush, "and when I went to fetch it, on opening the bush and looking down, I could not see it. I seemed to be looking on the dark brown ground with spots of sunlight through the leaves The little animal lay in such a position that the yellow spots were exactly where the vertical sun rays would fall, the yellow streaks resembling the slanting streaks of light from the side It was for a few minutes quite invisible, though I was looking down on it" No 47 of the journal of the same branch of the society is devoted completely to a Malay manuscript entitled "Hikaiat Shamsu'l Bahrain," which, however, has no claims to special interest, being of a common type

The address delivered by the Hon J Ferguson, president of the Ceylon branch of the Royal Asiatic Society, gives an interesting sketch of past and present scientific work in the island In natural science the most valuable recent publication is that of Prof Herdman, on the pearl oyster fisheries, with supplementary reports on the marine biology by other naturalists The mineralogical survey has led to the discovery of many novelties, including thorianite, the only thorium-bearing substance to be found in any British possession It is much to be regretted that the local government has been unable to provide funds for the establishment of an observatory, the want of which is much felt by the shipping trade, and was obliged to decline the offer of Mr A R Brown, one of the Cambridge school of anthropologists, to undertake a survey of the Veddas The suggestion made by Sir H. A Blake, on native authority, that the connection between mosquitoes and malaria was known to Susruta, a Hindu writer of the fourth century A D, has been examined by Prof Jolly, with the result that the term Masaka cannot be confined to the mosquito, but includes various other insects popularly believed to cause disease In regard to membership, the society is in a sound position In spite, however, of the president's optimism, we gather that the supply of papers is not so large as might be desired, and that some of the enthusiasm which has revived the sister society at Calcutta is needed at Colombo.

AGRICULTURAL EXPERIMENTS

WISCONSIN Experiment Station Twenty-second Annual Report—From the time of Thomas Andrew Knight onwards, horticulturists have remarked the effects of an excessive food supply on variability in cultivated plants; but one seldom hears of a case in which such pronounced results have followed excessive feeding as those which occurred in an experiment described by Mr E P Sandsten in the twenty-second annual report of the Agricultural Experiment Station of the University of Wisconsin. To a batch of tomato seedlings growing in a greenhouse a mixed manure consisting of 800 lb nitrate of soda, 600 lb sulphate of potash, and 1000 lb bone per acre was applied The seedlings soon began to vary, with the result that out of ninety-six plants scarcely any two were alike Some plants were dwarfed, others developed internodes of abnormal length, the leaves varied in size and shape; the blossoms were abnormal in form, the stamens were much modified, and in one case became "almost aborted," the pistils, on the other hand, were greatly overgrown, and some of the plants produced seedless fruits Two seedless types, a large- and small-fruited, were specially noticeable, and cuttings of those and of some of the other marked variations were made These were subsequently grown in an ordinary soil, and produced plants which retained all their abnormal characters

Variation in the Composition of Milk.—In Bulletin No 11 of the Edinburgh and East of Scotland Agricultural College, Dr Alex Lauder gives some interesting par-

details about the composition of the milk of a well-managed and well-fed herd of Shorthorn dairy cows. The herd, numbering twenty-two, was maintained for the purpose of supplying Rosslynlee Asylum with milk. The milk of each cow was weighed daily, and sampled weekly, the mixed milk of the herd was also sampled once a week. The investigation began in May, 1905, and lasted for a year. The cows were milked at 6.30 a.m. and at 4 p.m., and, as is always the case when the milking periods are unequal, the milk was found to be poorer after the longer than after the shorter interval. The morning milk averaged 3.15 per cent. of fat for the whole year, while the evening milk averaged 3.91 per cent. There was a marked difference in the milk of individual cows, one animal, for example, produced 635 gallons of milk during the year, containing 3.58 per cent. fat in the morning and 4.81 per cent. fat in the evening, while another produced 638 gallons, which contained only 2.96 per cent. fat in the morning and 3.5 per cent. fat in the evening. Until the middle of January the mixed milk of the herd always contained more than 3 per cent. of fat, but in spite of good management the quality then began to fall, and during the next three months the mixed milk contained less than 3 per cent. of fat eight times in the morning and four times in the evening, as the milk was sampled only once a week it must, therefore, have usually contained less than 3 per cent. of fat in the mornings in February, March, and April. Although the cows were liberally fed additional rations were tried for the purpose of improving the quality of the milk and four animals were given 2 lb. linseed cake and 2 lb. oats per head per day. In accordance with experience, it was found that the addition of concentrated foods to rations already liberal produced no improvement in the milk.

West of Scotland Agricultural College Reports on Experiments, 1906.—The seventh and eighth annual reports of the West of Scotland Agricultural College have been issued as a single volume. This volume contains reprints of four bulletins which have already been issued separately. Among the subjects dealt with are the uses of inoculating materials for leguminous crops. Several crops were treated, but the only positive results were obtained with lucerne. At two centres it was found that lucerne was much benefited by treatment with Hiltner's inoculating material. In the first case lucerne was sown on April 12 on land which had probably never grown this crop, and had certainly not done so for twenty-eight years. Part of the seed was treated and part untreated. Early in July the crop growing from treated seed began to show signs of improvement, and in August, when flowering, it stood 20 inches to 21 inches high, while the adjacent untreated crop was but 13 inches to 14 inches. It was noticed that the inoculating material only did good on land which was well supplied with phosphates and potash; on soil deficient in either of these inoculation produced no effect. At the second centre lucerne had been growing for a year before it was treated, and it was noticed that a few nodules had developed on the roots, but the crop was far from vigorous. On May 28 some sand was inoculated, and this was sprinkled over part of the lucerne. On July 15 the lucerne was cut, the treated plot then yielded 56 cwt. and the untreated plot 54 cwt. per acre, so that inoculation had not been effective. Directly after mowing however an improvement in the treated crop was noticed, and this improvement became more marked as time went on, so that when a second cutting was made on September 25 the land which had been treated with Hiltner's culture produced 74 cwt. per acre, as against 30 cwt. from the untreated soil. These experiments were made in 1905, when, at the instance of the Board of Agriculture, similar experiments were made in all parts of the country, and the West of Scotland tests illustrate the general result, which was that inoculating material proved useful for a leguminous crop newly introduced into a district, but was seldom beneficial in the case of crops commonly cultivated. The nodule organisms of these are abundant in most soils. Several of the experiments recorded in this volume deal with the best time of year at which to apply manures. In the case of turnips, the conclusion is stated that superphosphate, basic slag, kainit, and muriate of potash are better applied in spring than in autumn, for hay, on the other hand, it is better to apply potash manures in autumn than in spring. For both turnips and potatoes it was found to be more profitable to apply farmyard manure in spring than in autumn.

ANTIPODEAN BIRD-LIFE.[1]

In an illustrated pamphlet bearing the date 1903, and published at the Government Press, Wellington, Mr. R. Henry, who has for many years acted as caretaker of the bird-reserve on Resolution Island, furnishes a fund of interesting information with regard to the habits and life-history of the flightless birds of New Zealand, with notes relating to other species. As he himself remarks, if anybody ought to know what there is to be known about New Zealand birds it is the author, who has, *willy-nilly*, enjoyed exceptional opportunities of observing them. As might have been surmised, a large amount of space is devoted to the birds commonly known in this country as kiwis (Apteryx). It appears, however, according to the author that this usage is not justified, the name kiwi belonging by right only to the grey species and its immediate relatives, while such species as *A. australis* and *A. oweni* are designated "roa" by the Maori. Very interesting are the author's observations with regard to the breeding habits of these birds, among which the cock assumes the office of incubation. As regards kiwis, it is stated that although they live in nearly the same situations as rowas they prefer open ground, while the latter seek the densest shade of the forest. "Kiwis generally have white grubs in their stomachs, with things like big maggots, wire worms, and all that class, while the roas depend more upon earthworms, water-insects, and berries." When a roa becomes conscious of the presence of intruders it alters its usual stealthy gait to a loud tramp. Is this, it may be asked, defiance?

A very strange statement is made about the kakapo, or ground-parrot, namely, that it breeds only once in two years. This, however, is not all, for it is stated that in place of some individuals nesting in one year and others in the succeeding season the whole of the birds will breed in one particular year, while in the following year none will do so.

Continuing his remarks on the habits of the kakapo, the author observes that, "months before the appointed breeding season the male is developing an air sac in his throat which he can puff up like a drum, and which may act like a sounding-board to assist in making the curious drumming notes in the spring. This note is not unlike the boom of the bittern, but is repeated five or six times in succession, and can be heard at a great distance. It appears as if the breeding season were controlled by the males, for when there is no drumming in the early summer, there are no eggs or young ones."

Another bird about which the author has a good deal to say is the weka rail, or wood-hen, and it cannot be said that he gives it a good character, mainly on account of its egg-stealing habits. One of these birds, although it had never previously seen a goose in its life, seemed to know by instinct that the eggs of the latter would be buried in the ground, and promptly proceeded to disinter them. Apart from moas and the nearly extinct Notornis penguins are the last of the flightless birds to claim the attention of the author. He has, however, much to say regarding such species as black swans, paradise-ducks, grebes, moreporks, &c., and in the case of all these the ornithologist should find much to interest him in this little volume, which is certainly a storehouse of information with regard to the habits of New Zealand's birds. It may be hoped that the Government will not only see its way to maintain Resolution Island as a bird-sanctuary, but that it may establish other stations of the same nature.

1 "The Habits of the Flightless Birds of New Zealand; with Notes on other New Zealand Birds." By R. Henry. Pp. 88; illustrated. (Wellington, 1903.)
"Glimpses of Australian Bird Life." Thirty-one original photographs direct from Nature, with Notes by R. Hall. Pp. 63. (Melbourne: T. C. Lothian, 1906.) Price 1s.

"Glimpses of Australian Bird-life" is a praiseworthy attempt to encourage the study of the avifauna of the island-continent among field naturalists. The photographs, although on a small scale, are for the most part excellent, while Mr. Robert Hall's brief explanatory notes are (as might be expected) very much to the point. One of the most interesting species depicted is the whip-bird (or coachwhip-bird), while from the point of view of excellence in technique special mention may be made of the portrait of the so-called reed-warbler and its nest. R. L.

NOTES ON RECENT PETROGRAPHY

STUDENTS of the processes of sedimentation and of flocculation in clays should not overlook the three papers on sands and sediments, by Messrs. Mellard Reade and Philip Holland, that have been published in the Proceedings of the Liverpool Geological Society. The original analyses of sediments given in the second paper (vol. x., part i., 1905), and in the third now issued (1906), are distinctly valuable. Some of the specific gravities stated for clays seem a little high, but it must be admitted that we possess as yet far too little knowledge of our commonest sedimentary deposits. In vol. x., part ii. (1906), p. 136, the authors point out that "the experiments have, we think, demonstrated the existence of a mass of matter of unsuspected granular minuteness distributed throughout the sedimentary rocks of the earth.

We have strong grounds for thinking that the distribution of the finest sediment, in the form of what we may call quartz-dust, is oceanic." The abundance of quartz grains in some rocks popularly classed as argillaceous, such as "slates of coarse texture" (p. 156), is of course already familiar to agricultural investigators.

Mr. H. W. Nichols, in describing new forms of concretions (Field Columbian Museum Publications, Geological Series, vol. iii., No. 3, 1906), usefully brings to the front Forchammer's determinations of magnesia in the skeletons or shells of marine organisms, which were originally published in 1849. Mr. Nichols supports these by analyses of his own (pp. 48–9), *Corallium rubrum* giving him 0.32 per cent. of magnesium carbonate. Forchammer's Mediterranean Serpula yielded as high a figure as 7.64 per cent. The Zoantharia examined give only from 0.35 per cent. to 0.54 per cent.

Messrs. Allen, Wright, and Clement have experimentally investigated the minerals of the composition $MgSiO_3$ (*American Journal of Science*, vol. xxii., November, 1906), and have produced artificially the two pyroxenic types, monoclinic and rhombic, and the corresponding two amphibolic types. At atmospheric pressure (p. 415), the monoclinic pyroxene, $MgSiO_3$, a rare form in nature, is found to be the product of crystallisation from solvents; the material used for this experiment may be any of the forms of crystalline $MgSiO_3$. All the other forms of magnesium silicate (p. 437) pass into the monoclinic pyroxenic form at temperatures between 1150° and 1300°, depending on the crystal-form employed. Enstatite crystallises at lower temperatures than the monoclinic pyroxene. The amphibolic types have been produced by a rapid cooling, which, as the authors point out, is not likely to be the prevailing cause of their occurrence in natural rocks.

Mr. H. I. Jensen, in dealing with the volcanic area of the East Moreton and Wide Bay districts, Queensland (Proc. Linnean Soc. of New South Wales, 1906, p. 73), describes a number of trachytes containing riebeckite, some of which form important plugs or domes. Trachytes, as well as basalts, are recorded from Gough Island, in the South Atlantic, by Messrs. Pirie and R. Campbell (Proc. Royal Physical Soc. of Edinburgh, vol. xvi., 1906, p. 258). Mr. I. G. Sundell (*Bull. Comm. géol. de Finlande*, No. 16, 1905), writing in English, or American, affirms the importance of cancrinite as "a very abundant and doubtless primary constituent" of the syenites of the parish of Kuolajärvi in N. Finland. His paper, like many others from various parts of the world, shows the strong influence already exerted by the Chicago system of classifying igneous rocks.

Mr. G. K. Gilbert (Bull. Geol. Soc. America, vol. xvii., 1906, p. 321) discusses gravitational assemblage in granite, citing striking cases from the Sierra Nevada, where large crystals of felspar and hornblende have respectively assembled in aggregates in granite. An example of banded granite, where bands rich in hornblende and mica alternate with others rich in felspar and quartz, suggests to the author successive sedimentation. Unconformities occur in the banding (p. 324), a dark band always forming the base of the upper series, and truncating obliquely the edges of previous bands. Mr. Gilbert puts forward the view, as a hypothesis, that a pair of bands represents a unit of deposition from the original magma, gravitation playing a *rôle* in the process.

Mr. R. A. Daly, of Ottawa, whose work in the field of igneous absorption and intermingling is well known, states his case of the Moyie Sill in the Purcell Range with effective lucidity in the *Festschrift zum siebzigsten Geburtstage von Harry Rosenbusch* (Stuttgart, Schweizerbart'sche Verlagsbuchhandlung, 1906). His contribution is entitled "The Differentiation of a Secondary Magma through Gravitative Adjustment," and his argument for the assimilation of a felspathic quartzite-series by a gabbro-magma is supported by a number of chemical analyses. A granite zone intervenes between the gabbro and the overlying part of the quartzite-series, and the author holds that (p. 225) "there is clear chemical proof that the greater proportion of the elements in the granite could have been derived directly by fusion of the quartzite." The gabbro, in its onward passage, absorbed beds of quartzite, but (p. 228) "simultaneously gravitative adjustment has nearly restored the original composition, as the acid, assimilated material rose through the denser gabbro magma to the top of the sill." We need not subscribe as yet to Mr. Daly's view (p. 233 and previous papers) that the pure igneous magma in the earth's crust is of basic composition, since there may be a variety of pure magmas in a variety of localities, yet we believe that there is much soundness in his concluding sentence:—"The fact of 'consanguinity' among the igneous rocks of a petrographical province may be due as much to assimilation as to differentiation." G. A. J. C.

ARCHÆOLOGY IN ITALY

THE final rejection by the Italian Government of Prof. Waldstein's well-advertised project for an international excavation of Herculaneum gives the Rome correspondent of the *Times* food for reflection with regard to the alleged Chauvinism of Italian archæologists, who will allow no foreigner to take part in Italian excavations, notwithstanding the fact, which they admit freely enough, that Græco-Roman antiquity is the property of the whole world, and not of Italy alone. While admitting that the postponement of the excavation of Herculaneum until such time as Italy can do it by herself does not much matter from the scientific standpoint, since "the treasures which lie beneath Resina are in safe keeping, and might remain undisturbed for centuries," the correspondent remarks that this is by no means the case with regard to other sites, which cry aloud for speedy excavation for valuable evidence is in their case being destroyed daily by the "march of modern improvement." To do the work, Italy can muster neither sufficient money nor sufficient men, especially the latter. Yet she will not invite foreign aid which would willingly and gratefully be given by archæological students all over the world. As the *Times* correspondent is obliged regretfully to admit, "The foreigner is at liberty to pay his *lira* for admission to museums and other places; he may even give a round sum for the completion of some work in which he is interested, as long as he does not wish to help in carrying it out himself; he may turn his talents to such use as advertising the achievements of Italian archæologists or translating their books into another language; he may show an intelligent and devoted interest, but it must be from a discreet distance. That, at least, seems to be the moral of all the recent relations between Italy and other countries in the archæological questions which have come to the front during the last twenty years or so. One would willingly believe it otherwise; one would gladly put a more literal and liberal interpretation on their professions of confraternity; but how is it possible

to do so unless Italian archæologists support their words by actual deeds? One simple fact outweighs all their written and spoken utterances Nowhere in Italy is any foreign enterprise at work, and never has any foreigner been invited to give his time and his talents to what is, in their own admission, a common cause If Italian archæologists would pay to other nations the graceful compliment of employing, now and then, their students as assistants, if those derelict excavations on the shore of the Gulf of Taranto—whose need is so pressing and whose secrets are so necessary to history—could be, even temporarily, confided to foreign institutions, then, and not till then, their assurances would carry weight '

PROGRESSIVE WAVES IN RIVERS [1]

THE stationary waves produced by the interaction of a rapid stream with its bed have been the subject of several investigations The author finds that by a special mode of vision described in the paper the simultaneous presence of waves progressing down stream can be readily detected

In a very shallow stream with a steep channel the progressive wave becomes the principal and obvious, instead of a subordinate and obscure, feature In this case the velocity of flow is much reduced by friction The slightest excess of retardation at any point momentarily increases the depth there, and increase in depth (where the depths are small) increases the velocity, at any rate in the upper layer Continuous motion is therefore impossible and is replaced by a gushing flow If the bed be of nearly uniform cross-section, the gushes take the form of regular transverse progressive waves If, on the other hand, the cross section of the channel be very uneven, there may be no lateral coordination, and the intermittence of flow is only detected by the rushing sound and the beating action of the water against an immersed body

Measurements showed that the total velocity of these roll-waves was equal to the velocity of the current *plus* the velocity of a long wave in water of the observed depth

All waterfalls tend to break up into conical masses called water rockets, and in rare cases a fall may be seen which consists of a slow procession of well separated "rockets" ranged in roughly horizontal lines A case is described in which this beautiful appearance was due to the formation of roll-waves above the fall

Roll-waves spontaneously arising in very shallow conduits occur in groups, and the growth of amplitude and wave-length was measured in the case of the conduit of the Grünnbach at Merligen, on the Lake of Thun

Roll-waves in shallow mountain rivers due to heavy rains in the gathering ground of the tributary streams are solitary, and, coming without warning before the turbid waters arrive, are dangerous to anglers who are familiar with the phenomenon on the Tees Ure Swale and other rivers The uniform cross-section of the Tees near Barnard Castle and of the Ure near Aysgarth, is peculiarly favourable to their formation and growth

The cross-stream progressive waves observed by the author in the Whirlpool Rapids of Niagara are a secondary phenomenon arising from the varying amplitude of the familiar stationary waves, a variation which the author traces to its cause When their interference occurs at the intersecting crest of two stationary waves there ensues one of those great leaps of water which present so splendid an appearance in these rapids The author invites special attention to the points in which his explanation of these phenomena in Niagara Rapids differs from those hitherto current

Tidal bores are the only form of progressive wave in rivers which had hitherto received much scientific attention. The author deals with the question of what determines the place of origin of the tidal bore in the River Severn, and what is the cause of its apparently capricious variation in magnitude Briefly, the bore originates where the slope of the channel is steep but in the *upper*, not the lower, part of the steep slope because there is in the upper part no alternative channel among the sand-banks for the last-of-ebb and first-of-flood respectively to pursue, but at the end of a set of spring tides the flood has so far cut in the sand an alternative, straight channel that the height of the bore is reduced An excess of land-water, on the contrary, so strengthens the ebb that it tends to make a deep, solitary curved channel up which the flood must force its way increasing the height of the bore

[1] Abstract of a paper by Dr Vaughan Cornish in the *Geographical Journal* for January

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

THE Western University of Pennsylvania has conferred the honorary degree of LL D upon Sir Robert Ball, Sir Robert Cranston Sir William Turner, Sir William Preece, Mr Marconi Dr Chalmers Mitchell, Dr John Rhys, the Rev E S Roberts (Master of Caius College, Cambridge), and Mr Edwin Abbey

A CONFERENCE on the teaching of hygiene and temperance in the universities and schools of the British Empire will be held at the Examination Hall Victoria Embankment, on St George's Day April 23 The chairman at the morning session will be Lord Strathcona and at the afternoon session Sir John Gorst

THE annual exhibition of students' work will be held at the Borough Polytechnic Institute on Saturday April 20 from 6–9 30 p m The workshops laboratories, drawing offices girls' trade school domestic economy rooms and other departments of the institute will be open for inspection, and practical work will be carried on during the evening

THE *Times* correspondent at Ottawa reports that the medical building of McGill University Montreal was destroyed by fire on April 16 The museum, with its priceless specimens, is ruined, but a portion of the valuable medical library was saved The loss is placed at 100 000*l*, of which 70 000*l* is covered by insurance The origin of the fire is unknown but incendiarism is suspected

THE accommodation provided at University of London University College for the schools of engineering and of architecture will be considerably extended before the beginning of the next session in October by the additional space which becomes available through the removal of University College School to Hampstead The Andrews scholarships are offered for competition in May one of these scholarships value 30*l* in science and mathematics, is tenable in the school of engineering

A PARTY of students of zoology from the Birkbeck College spent part of their Easter vacation in Jersey shore-collecting during the prevailing low tides More than one hundred and fifty species of shore-life were obtained, illustrating nearly all the animal phyla The success of the visit was in great part due to the advice and guidance of Mr J Sinel, formerly director of the Jersey Marine Biological Station A selection from the species collected formed a very interesting exhibit at the annual exhibition meeting of the Birkbeck Natural History Society, which was held on Saturday evening April 13

THE reports from the universities and colleges which participated, during the year ended March 31 1906, in the annual grant of 100 000*l* made by Parliament for "university colleges in Great Britain," and from the three colleges in Wales which receive a grant of 4000*l* each, have now been published (Cd 3409) by the Board of Education Much instructive information can be gathered from the income and expenditure accounts provided by the various institutions With an income of 42 819*l*, Birmingham University at the end of the year's working had a balance in its favour of 2557*l* Leeds University though it started the year with 1568*l* in hand after expending 45 744*l* ended the year with 395*l* only to the good With an expenditure of 53,162*l* Liverpool had 532*l* in hand at the end of the year Manchester with an income of 59 155*l*, came to the close of the year with 131*l* to the good Sheffield, which in the year under consideration was still a university college was with an income of nearly 25,000*l* about 1500*l* in debt at the end

of the year Bristol with a much smaller income, did not spend it all Dundee just about made both ends meet Bedford College, London, had a small deficit King's College, London, with an income of 33,282*l*, managed to save 618*l* University College, London, spent rather more than its income. The college at Newcastle had a deficit Nottingham had been adopting a saving policy with a view to future developments, and arrived at the end of the year with a good balance Reading spent more than it received, and Southampton was in want of money Though the conditions have been modified to some extent since the year with which the report deals there is still the same careful and economical management required at all these colleges, and desirable improvements and developments have to be postponed for lack of funds We hope it will not be long before the Government is able to provide more than 100,000*l* for higher education, and that increased State aid will be supplemented by greater munificence on the part of our men of wealth

A NEW era in the chemical department of the Scottish universities has been inaugurated by the erection of a chemical research laboratory at St Andrews University by the munificence of Prof. Thomas Purdie, F R S at a cost of about 9000*l* Moreover, the 5000*l* originally set aside by the University Court from the Carnegie trust

The Purdie Chemical Research Laboratory, University of St Andrews

quinquennial grant for buildings, &c, to aid in this work has by a subsequent arrangement of the Court and the Carnegie trust, been constituted an endowment for the upkeep of the chemical research department A teaching chemical laboratory had previously been presented to the University by the generosity of Mrs Thomas Purdie late of Castlecliffe The former occupants of the chair, viz Profs Connel and Heddle, were distinguished in their way, viz, the former in regard to the dew point and other subjects, and the latter in mineralogy and the chemistry of minerals, but chemical research proper dates from Prof Purdie's appointment in 1884 and has now been firmly established in the University The substantial new building, which is seen in elevation in the accompanying illustration, provides still further facilities for post-graduate work On the ground floor is a graduates' research laboratory with ten benches, each with high- and low-pressure water-taps, electric light and power, and there are also balance, operation physical and dark rooms Ventilation, light and heat are perfect, so that the workers are under the best possible conditions On the second floor is the professor's laboratory for four workers, a library, museum, spacious lecture-room, and various preparation rooms The progress of the University as a chemical research school has been rapid, for previous to 1884 the accommodation was altogether inadequate. Now the facilities for teaching and research are not behind those of any of the modern German institutions Moreover not only St Andrews students, but other capable workers are welcomed Working in conjunction with the professor or lecturer on organic chemistry, students qualify for various scholarships, e g the Berry, Carnegie, and 1851 Exhibition scholarship, the research degree of London University, and the D Sc degree The school has especially been noted for its work in optical activity and the chemistry of the sugars, but other subjects of biological interest have also been dealt with

SOCIETIES AND ACADEMIES

London

Royal Society December 6, 1906 —"The Chemistry of Globulin" By William **Sutherland.** Communicated by Dr C J Martin, F R S

The author's object in the present paper is first to establish simple formulæ for the more important of the experimental results obtained by Hardy and Mellanby, then to interpret these in their bearing upon the chemistry of globulin in connection with a theory of colloids, and finally to find the molecular mass (weight) of globulin

By expressing the experimental results of Hardy and Mellanby in simple formulæ, it is shown that the solution of globulin and its precipitation take place under simple conditions of chemical equilibrium For example, if p is the fraction of a globulin suspension dissolved in a salt solution the concentration of which is the fraction q of C that is required just to dissolve the whole of the suspension, we get equation (1) $p(1-q)=Aq(1-p)$, in which A is the ratio of a velocity of solution to a velocity of precipitation Mellanby's discovery of the dependence of M/C on valency and ionic velocity is applied to MA/C, M being molecular mass, and it is shown that when temperature varies, not only does MA/C depend upon the viscosity of the solvent water, but also on a function of temperature given in an equation which expresses the part played by globulin It is noteworthy that this function has a minimum value about 40° C, near the temperature of warm-blooded animals

For the precipitation of globulin by excess of $(NH_4)_2SO_4$ an equation is established, namely, $p(1+p)=28\ 8(c-0\ 152)$, p being the fraction which the precipitated globulin is of the whole, and c the concentration of the $(NH_4)_2SO_4$ solution in grams per cubic centimetre

Then follow formulæ for the remarkable precipitation of globulin by acids from solution in neutral salts. From these it appears that three compounds of globulin react in producing this precipitate

Section iv is devoted to a theory of the colloidal state, namely that a colloid consists of molecules which are chemically united neighbour to neighbour by the action of valencies which are usually latent.

According to this chemical theory of the colloidal state, the term molecule ceases to have a useful meaning when applied to a colloid, so the term semplar is used to name that structure which is repeated like a pattern in three dimensions through a colloid By suppression of the colloid producing valencies of doublets a mass of semplars is caused to fall into a collection of separate molecules. In illustration of the usefulness of this theory, it is applied to show the dependence of the coagulating power of an ion on its valence It is then applied also to explain the remarkable fact that the amount of globulin dissolved by

a given salt solution from a globulin suspension depends on the concentration of the suspension The action of the ions of a neutral salt in dissolving globulin is treated as only another manifestation of the same electrical effect which enables them to coagulate arsenious sulphide This theory of the colloidal state leads to a theory of equation (1) and of the laws of A in it, especially that MA/C is proportional to the sum of the squares of the valencies of the ions of the electrolyte

In Section v the experiments of Hardy on the conductivities of globulin solutions are expressed by formulæ which admit of very simple interpretation, and connect these conductivities with those of ordinary electrolytes

In Section vi globulin is shown to have probably a molecular mass 40,000 and a basicity 2, the alternative being a mass 60,000 and basicity 3 Further experiments like those of Hardy on the ionic velocity of globulin and also on the coefficient of diffusion of globulin solutions would decide the matter, though doubtless various globulins differ in mass and basicity A group, $C_{12}H_{20}N_3O_4$, related to polypeptides and peptones, is shown to be the predominant structure in albumins The discrepant results of different experimenters on the precipitation of albumin by heavy metals fall into harmony when it is proved that they precipitated different integral numbers of a group such as this in combination with an equivalent of heavy metal

February 7—"Experiments made to determine the Conditions under which 'Specific' Bacteria derived from Sewage may be Present in the Air of Ventilating Pipes Drains, Inspection Chambers, and Sewers" By Major W H **Horrocks** Communicated by Colonel D Bruce, C B, F R S

Most sanitarians at the present time believe that when sewage is in a state of putrefaction and gas bubbles rising through it, are bursting at the surface, bacteria may be ejected into the air of sewers It is also considered possible that when sewage has dried on the surfaces of pipes bacteria may be separated as dried particles and carried some distance by currents of air passing through the pipes But it is not generally credited that the mere passage of infected sewage through a well-laid drainage system will also cause the ejection of specific bacteria into the air contained in the pipes The experiments detailed show that —

(1) The bursting of bubbles at the surface of sewage under artificial and natural conditions may cause the ejection of bacteria, which, if air currents are present, may be carried some distance

(2) Specific bacteria dried on the ventilating pipes of a drainage system may be separated and carried by currents of air passing through the system

(3) Specific bacteria may be ejected from *fresh* sewage flowing through a sewer under natural conditions independently of the creation of bubbles and the separation of dried particles The ejection of bacteria occurs, not only when use is made of naked microbes such as are obtained from growths on agar but also when typhoid stools are employed as the infecting agent

The results obtained, especially as regards the ejection of bacteria from fresh sewage are of great importance, and indicate that the disconnection of a house-drainage system from a public sewer is sound in principle, and that it would not be wise to remove the disconnecting trap and ventilate sewers by means of house-ventilating pipes or soil pipes

Royal Microscopical Society, March 20 —Dr J W H Eyre vice-president, in the chair —Some South African Tardigrada J **Murray** The author was indebted for the materials for his paper to Mr W Milne, of Uitenhage, Cape Colony, who, from time to time in 1906, forwarded moss containing bdelloid rotifers from various parts of Cape Colony In addition to the rotifers, which were abundant, the moss yielded many Tardigrada Fourteen species were found belonging to the genera Echiniscus Milnesium, and Macrobiotus Eight out of the fourteen species are distinct from any previously known —Notes on a peculiar habitat of a Chlorophyte, *Myxonema tenue* A D. **Hardy** The *Myxonema tenue* is usually found in rapidly flowing water frequently attached to submerged parts of river-side plants, but more often to stones and dead twigs, it is also found in the locality in stone-paved gutters in which there is a rapid flow of water The author also found it growing feebly in a small fish pond, about 10 feet diameter, where the water was nearly stagnant, but on some gold fish in the pond it grew luxuriantly, and the author thinks that some interest attaches to the adaptation of this stream loving Myxonema, which unable to thrive in stagnant water, yet flourished on moving objects where it obtained necessary water friction It may be added that the effect of this algal growth on the fishes was their premature death

Mathematical Society, April 11 – Sir W D Niven, vice president in the chair – An introduction to the metrical geometry of space of *n* dimensions H **Bateman**. —A note on Perott s theorem H **Hilton** —Poisson's integral and its relation to the proof of Fourier's theorem Dr F W **Hobson** —The values of the parameters for which a definite integral can be zero H **Bateman**.

PARIS

Academy of Sciences, April 8 —M A Chauveau in the chair —The photography of the infra-red solar spectrum G **Millochau** By the use of alcoholic solutions of malachite green full details of the exact method being given the author has been able to prepare plates of high sensibility in the infra-red region By the use of these plates photographs have been taken of the region 0·750 μ to 0·950 μ one Ångstrom unit having a length of about 0·1 mm These plates show that the band A has the same structure as the band B The line Z previously described as a short band in the infra red, has now been resolved into lines — The surface engendered by a circular helix Eugène **Barré** —A problem of analysis intimately connected with the problem of cooling of a heterogeneous bar W **Stekloff** —Orthogonal systems of functions and the equation of Fredholm Frédéric **Riesz** - The altitude of the Grand Pic de la Meije Paul **Helbronner** The mean result of the measurements is 3982·5 metres (summit of the signal) differing only by 4 metres from the earlier result of Durand —The action of a magnetic field on ionised air in motion, A **Blanc** On the hypothesis that the mobilities of the ions are not modified by the magnetic field, an assumption shown to be accurate by direct experiment, it is found that the negative ions have a greater mobility than the positive ions, the ratios obtained varying between 1 and 1·6, the average of fourteen experiments giving 1·32 - The oscillations of a higher order (harmonics) in the electric spark G A **Hemsalech** The existence of harmonics in the electric spark is clearly demonstrated experimentally by photographic means, an enlarged reproduction of one of the photographs being shown It was found that the harmonics are in great part the cause of the luminosity of the metallic vapour in the spark -The constitution of the atom and the law of Colomb H **Pellat** It was shown in a previous paper that to bring the current theory of the atom into harmony with experimental results either the atom must have a form approximating to a flattened disc or Colomb s law ceases to be applicable at intra-atomic distances In the present communication it is proved that a flattened form of the atom would not be stable and consequently Colomb's law must cease to be exact at the very small distances of the order of intra atomic distances the attracting force must increase less rapidly than the inverse of the square of the distance or the repulsive force more rapidly —Some observations concerning the note of M Pellat on the constitution of the atom Th **Tommasina** M Pellat has assumed that the atom as a whole is neutral from the electric point of view if this hypothesis is not true the further reasonings of M Pellat fall to the ground —An apparatus for measuring the flow of liquids M **Krebs** A description of a simple apparatus giving at any instant the flow of a liquid in litres per hour It has been successfully employed in measuring the consumption of petrol in trials of petrol motors—Remarks on the preceding note M **D'Arsonval** The apparatus is remarkable for its simplicity and exactitude, and will be of service in a great number of laboratory experiments —Positive light P **Villard** —The nickel tin alloys Léon **Guillet** Referring to a recent

publication by M Vigouroux on this subject, the author gives a *résumé* of work already published concerning the nickel-tin alloys by Guettier, Gautier, and himself —Some properties of the alkaline protoxides E **Rengade** At 400° C these oxides are decomposed into the dioxide and the metal, the latter volatilising Liquid ammonia converts them into mixtures of hydrate and amide Hydrogen at 180° C to 200° C reduces the oxides of rubidium, potassium, and sodium, forming a mixture in equimolecular proportions of hydrate and hydride —Contribution to the study of the oxybenzoates Œchsner **de Coninck** - Iodine derivatives of the methyl ethers of pyrocatechol F **Tassilly** and J **Leroide** —Sands and shingles of the Pas-de-Calais René **Bréon** A determination of the mineralogical composition of these sands and shingles shows that these minerals bear no relation to the rocks in the surrounding strata They arise from old igneous rocks the nearest deposits of which are 250 to 300 kilometres distant For the rocks and shingle the theory of ice transportation is a possible one but this explanation can hardly apply to the transportation of many millions of cubic metres of sand, and the cause of the appearance of the latter remains unknown —The artificial coloration of minerals Paul **Gaubert.** In opposition to the views of Suida, the author is of opinion that the artificial coloration of fibres of chrysotile and other crystallised minerals is a purely physical phenomenon —Tchernichewite, a new amphibole L **Duparc** and F **Pearce** —The presence of *Ustilago Maidis* on the adventitious roots of *Zea Mais* and of its *quadricolor* variety and on the biomorphoses which it presents M **Chifflot** —Observations on suprarenal fat V **Babès** —The purification of sewage by turf filters Henri **Pottevin** An account of experiments carried out for several months on a single filter The rate of filtration was 400 litres per square metre per day, and the purification effected, details of which are appended was very satisfactory —Contribution to the study of the food of the sardine Casimir **Cépède** —Characters of the intertropical atmospheric circulation L Teisserenc **de Bort** and L **Rotch**

THE DEVELOPMENT OF CHEMICAL THEORY

A History of Chemical Theory and Laws By M M Pattison Muir Pp xx+555 (New York John Wiley and Sons, London Chapman and Hall Ltd., 1907) Price 17s net

THIS book, as the author remarks in several places, is not intended as a history of chemistry, but as an account of the development of chemical theory, an account of attempts "to describe, to set in due order, and to connect the changes of composition and the changes of properties which occur simultaneously in systems of homogeneous substances, and the conditions under which these changes proceed" Or as the author again expresses his intention, it is "to trace the forms which the two fundamental inquiries of chemistry have presented at different periods, to describe some of the methods which have been used to find answers to these inquiries, and to set forth the general results of the application of these methods" The two fundamental inquiries relate to the questions, "What is a chemically distinct substance?" and "What happens when chemically distinct substances interact?"

These questions are treated historically In answer to the first, the author deals with the "recognition of homogeneous substances, and the description of chemical changes as the interactions of those substances, the marks of elements and compounds, the laws of chemical combination, the atomic hypothesis, the molecular and atomic theory, the composition of homogeneous substances—allotropy, elements which do not react, and chemical nomenclature and classification" In answer to the second question, an account is given of "the classification of homogeneous substances, acids, bases and salts, radicals, types, dualism, the unitary hypothesis, chemical equivalency, isomerism and constitutional formulæ, the hypothesis of ionisation, the periodic law, the conditions and laws of chemical change, chemical affinity, chemical equilibrium, and lastly, the elucidation of chemical reactions by measurements of physical properties"

In pursuit of this plan, the author treats first of ancient conceptions up to the year 1780, Lavoisier's systematisation is next considered, then follows a historical sketch of the doctrine of atoms, leading to the differentiation of the atom and the molecule An account of more modern work is here introduced, in which the van 't Hoff-Arrhenius extension of gaseous laws to dilute solutions is gone into in some detail, and the conception of a molecule having been developed, allotropy is treated of as due to molecular complexity or arrangement The inert gases of the argon group are next mentioned, and in an appendix chemical nomenclature and notation

In the second part of his book Mr Muir discusses the classification of substances into acids, bases, and salts, he describes the development of the theory of types and radicals, leading to chemical equivalency; and he extends these conceptions to cover the field of molecular structure, dealing with isomerism and constitutional formulæ

The next section treats of ionisation, then follows a short account of the periodic classification In a third section the subjects considered are chemical affinity, chemical equilibrium, the relations between the physical properties of substances and their chemical reactions, as exemplified by their optical properties and their thermal behaviour

These subjects are illustrated by suitable extracts from the works of the investigators who forwarded the theories Quotations from Boyle, Priestley, and Lavoisier give an idea of these authors' styles, and render clear the subject-matter which is under discussion To give an instance —

> "To-day it is possible to recognise a certain resemblance between the saying of Stephanus of Alexandria (about 620), 'it is necessary to deprive matter of its properties in order to draw out its soul' and the statement of Lavoisier (1789) that the object of chemistry is 'to decompose the different natural bodies and to examine separately the different substances which enter into their combination' The first statement rested on a sweeping and superficial glance over an intricate maze of occurrences, and it produced little accurate knowledge The second statement was a result of the penetrating study of a few detached events, it was a translation of the first statement into expressions which could be directly applied to a vast number of particular phenomena, and in a few years it produced a science"

So far as possible the authors alluded to tell their own stories, and the reader's attention is directed by Mr Muir to the salient points in their conclusions

It is better, on the whole, to treat chemical science as Mr Muir has treated it, in following out the history of the development of each idea, so far as that is possible, than to attempt a chronological history, the one is the philosophy of history, the other is apt to be overburdened with unconnected detail A third plan is the biographical one, to select certain chemists who have contributed to the advancement of their science and to show by an account of the life-work of each, how far discovery has been furthered There are difficulties in all methods of treatment, probably the one chosen by Mr Muir tends most towards lucidity

In his preface, Mr Muir writes —

> "Some may say I have omitted much that is important, others may think I have included not a little that is trivial In such matters a writer must use his own judgment, after he has trained it to the best of his ability"

And at the beginning of the chapter on chemical equilibrium, he says —

> "He who would describe in detail the historical development of chemical equilibrium must be a chemist, a physicist, and a mathematician, he must be a man of great learning, vast audacity, and much literary ability"

In his own judgment Mr Muir is quite unable to attempt the task, but his estimate is too modest It must certainly be acknowledged that he has displayed great learning and much literary ability As to the audacity, it is for himself to judge W R

NIGER DELTA NEGROES

The Lower Niger and its Tribes By Major Arthur Glyn Leonard Pp xxii+564 (London Macmillan and Co, Ltd) Price 12s 6d net

THERE is about this book, which is undeniably interesting, a certain haziness in its preliminary observations, a lack of sharpness in its detail, in the geography and natural history, which suggests a photograph slightly out of focus You get a general idea of the scene, but you cannot be quite sure as to the species of the trees or flowers, or whether it is horses or cows that are feeding in the distant fields This want of exactitude is probably due to the fact that the author has seemingly allowed several years to elapse since his departure from the Niger delta before transcribing his remembrances from his notes

The book, in its good features and in its faults, is a rather striking example of the new school of literature dealing with negro Africa which has arisen since the publication of Mary Kingsley's West African studies This remarkable woman founded a new school in African studies which in some directions—politically more especially—has wrought much good In convincing the British white man—official, missionary, or merchant—that the black is not the half-animal savage which many unthinking people had considered him to be, that there is much good in his native ideas of religion and social economy, Mary Kingsley came near to being a genius, for she grasped and expressed many truths about the negro of West Africa which had been perceived by those who did not write or speak, and had been overlooked by many who did both Her gift of intuition enabled her to arrive at these conceptions with very little help from language In her two or three years spent on the West Coast of Africa she never mastered a sentence in any African language, and all her inquiries were conducted through English-speaking interpreters Those, therefore, who have had more scientific training in the affairs of Africa cannot always bring themselves to agree with Miss Kingsley's statements or with the deductions drawn therefrom, but she carries conviction in so much of her work that it is not necessary to attack it as a whole In a journal of exact knowledge like NATURE it is as well, however, to put ethnologists on their guard, to demand the utmost precision of statement from new writers on African subjects, even perhaps to beg of those writers to furnish an array of accurate and useful facts, and not attempt to add their own deductions, which may be based on a very limited knowledge either of Africa or the human race in general

Miss Kingsley's disciples are too fond of coining words in "ism" and "ality," and out of these they create a windy philosophy of German nineteenth-century type which they then declare to be the true meaning of African religious ideas. In one book—not that under review—much of this philosophy is based on a series of sentences in a native language, the words for which, though correctly taken down, are followed by a translation which is often incorrect and misleading Major Leonard in one chapter has cited a number of interesting proverbs and several fables, but he does not tell us from which tribe each is drawn, and his work would have carried more conviction if he had given the actual rendering in the native language, so that specialists could have satisfied themselves as to the correctness of the translation

There is a good deal more accuracy and definiteness in the way the author traces the history of the Ibo and Jekri and Efik peoples, and he imparts much useful and novel information regarding the Ijo tribe, which not differing physically from the other negro inhabitants of the Niger delta, nevertheless possesses a language of very isolated type with no clear relationships The descriptions of the native gods and the spirits who are believed to exist in trees, earth, water, and sky are valuable, and, so far as the reviewer can judge, accurate, moreover, they are given in a manner and style certain to arrest and retain the reader's interest "Horrors" are dealt with in sober language, but some of the incidents cited might be the nucleus of powerful stories such as Grant Allen used to write To those writers of fiction who place their stories in Africa, Major Leonard's book will supply many a sensational episode, while at the same time keeping within the limits of actual fact

Much interesting matter is also included dealing with the languages of the Niger delta and of Old Calabar The reviewer, however, cannot quite endorse Major Leonard's theories as to etymology and the inter-relationship of certain language groups, but these theories are presented without dogmatism, and are worth consideration

The book is therefore interesting, and more than half of it consists of a well-presented statement of the religious beliefs, manners, and customs of the Ibo people more especially, and also of the Ijo, Jekri, Efik, and Ibibio If Major Leonard could have omitted some of the preliminary chapters dealing too much with speculative philosophy and have confined himself to the interesting statement of his own personal observations, he would have produced a work of compact value Even as it is, those engaged in African research will find it an excellent guide in studying the negroes of the Niger delta

H H, J

PRACTICAL PLANT-PHYSIOLOGY.

Vorschule der Pflanzenphysiologie, eine experimentelle Einführung in das Leben der Pflanzen By Prof L Linsbauer and Dr K. Linsbauer Pp xiv+255 (Vienna Carl Konegen, 1906)

THIS book consists of instructions for the performance of 295 experiments in plant physiology in the widest sense It includes, not only the physiology of nutrition and movement, but also a

section on reproduction which takes in the mechanism of pollination, asexual reproduction by means of bulbils, experiments on regeneration, on the behaviour of potato tubers, and on grafting. The instructions are well arranged, and they form, with accessory explanations, a fairly continuous whole. A useful appendix is added, in which the needful outfit in apparatus and reagents is given, together with hints on laboratory methods. The book is intended partly for the "cultivated layman" and partly for the students of the Gymnasium and Realschule. It will, however, prove useful to the teachers in English universities, as well as to others who have discovered the wisdom of making even advanced students perform for themselves elementary experiments.

We are inclined to think that the cultivated layman will be frightened by the first twenty pages of the book, which contain a large number of rough qualitative estimations of the chemical compounds occurring in plants. This is excellent for the laboratory, but is hardly readable by one who does not repeat the experiments—and we cannot imagine the cultivated layman working his way through them. This, however, is not the fault of the authors, and it is only fair to say that the book in general is far from being unreadable.

In a future edition the authors would be well advised to give scientific names, if only for the sake of foreign readers, who cannot be supposed to know what plants are meant by *Sommerwurz* or *Mauerpfeffer*. In some few cases the instructions want a little re-editing. Thus, in exp. 123, p. 82, the student is directed to compare the assimilation of a withered leaf with that of a fresh one, but he is not told that the absence of assimilation in the withered leaf is due to the closure of its stomata. The experiment is, in fact, incomplete; what is missing is a repetition of Stahl's proof that the leaves of certain plants the stomata of which do not close on withering are capable of assimilating in that condition. At p. 45 the treatment of the function of the stoma in gaseous interchange is not all that could be wished. The reader will have a singular view of Brown and Escombe's researches if his knowledge is confined to what he can learn in the present volume.

The experiments (p. 52) on the effect of freezing leaves would be more instructive if the ice-injection of the intercellular spaces were studied on a hardy plant such as ivy. In the second experiment, on p. 78, a Tropæolum leaf is recommended for use in experiments on the passage of air through vegetable membranes. But this is hardly allowable, since the leaf in question is well supplied with stomata on both surfaces.

In spite of a few oversights in its pages, we do not hesitate to recommend the work of the brothers Linsbauer to our readers. The methods prescribed are simple and trustworthy, and the book has a merit which is rare in text-books, namely, that it is obviously written with sincere interest in the problems set before the learner.

F. D.

SOME RECENT MATHEMATICAL WORKS

Space and Geometry. By Dr. Ernst Mach. Translated by Thos. J. McCormack. Pp. 148. (London: Kegan Paul and Co., 1906.) Price 5s. net.

Irrational Numbers and their Representation by Sequences and Series. By Dr. Henry Parker Manning. Pp. vi+123. (New York: J. Wiley and Sons; London: Chapman and Hall, Ltd., 1906.)

Auslese aus meiner Unterrichts- und Vorlesungspraxis. By Dr. Hermann Schubert. Vol. iii. Pp. 250. (Leipzig: G. J. Göschen, 1906.)

Leçons de Géométrie supérieure. By M. E. Vessiot. Pp. viii+322. (Lyons: Delaroche et Schneider; Paris: A. Hermann, n.d.) Price 12 francs.

La Géométrie analytique générale. By H. Laurent. Pp. vii+151. (Paris: A. Hermann, 1906.) Price 6 francs.

N. H. Abel, sa Vie et son Œuvre. By Ch. Lucas de Peslouan. Pp. xiii+169, with portrait. (Paris: Gauthier-Villars, 1906.) Price 5 francs.

Theory of the Algebraic Functions of a Complex Variable. By Dr. John Charles Fields. Pp. vii+186. (Berlin: Mayer and Müller, 1906.)

Recherches sur l'Élasticité. By P. Duhem. Pp. 218. (Paris: Gauthier-Villars, 1906.)

IF reform of mathematical teaching is to mean anything real, it is necessary that the teacher should possess a much more extended survey of his subject than is conveyed in the ordinary English text-book. There could be no more suitable book for giving the elementary or secondary teacher some intelligent ideas about geometry than Dr. Mach's series of essays. In them the subject is treated in its physiological, its psychological, and its physical aspects.

The first essay thus deals with the relation of the spatial concept to the senses. In the second we have an attempt to trace the natural development of geometry from psychological causes, while the last essay discusses the subject from the point of view of physical inquiry. Incidentally, a number of illustrations are introduced, some of which are admirably adapted for teaching purposes. There could not be a better object-lesson in the elementary properties of Euclidean space than the indefinitely extended pavement formed of equal and similar triangles discussed on p. 59. From it can be read off all the principal properties of parallels and parallelograms, the relation between the three angles of a triangle, and also the main properties of similar triangles the sides of which are commensurable.

Dr. Manning's book on irrational numbers contains a presentation in a simple form of another field of mathematical inquiry, such as is also eminently suited for placing in the hands of the ordinary schoolmaster. We have decided that the geometry of proportion shall be taught to schoolboys without reference to irrational quantities, but we have not yet eliminated a spirit of reckless extravagance in the quite unnecessary use of infinite series, often with total disregard for their convergency. In Dr. Manning's treatment an irrational number is defined

as forming a point of separation between rational numbers of two classes, the numbers of one class being less than those of the other This definition appears to involve the assumption (pp 7, 10, &c) that the point of separation is unique, in other words, that there cannot be two irrational numbers which have not some rational number separating them Perhaps this assumption may be regarded as a definition of equality of irrational numbers, in any case, the inquiring reader would find it necessary to examine more fully the references to Dedekind's and Cantor's writings given on p 56 Once the assumption or definition is made, the representation of numbers by sequences readily follows The theory of limits is discussed on p 57, and in the following chapter the notion of a sequence is shown to give rise to that of a series The remaining portion of the book is mainly devoted to the study of convergence, and includes the well-known multiplication theorem and applications to the still better-known binomial and exponential series

Prof Schubert is rightly regarded as an authority on the teaching of mathematics, but if this description leads the English reader to expect that the present selection of lecture notes will consist of a mere repetition of the "school geometry" and "graphs" which are being ridden to death in England to the exclusion of other equally important reforms, that reader will be greatly disappointed Dr Schubert has rather shown us what can be done by any teacher who will endeavour to make himself "a snapper up of unconsidered trifles" He finds, in the first place, that the determination of centres of gravity is not well treated in text-books either on mechanics or on the calculus, accordingly, this problem forms the subject of the first section The discussion includes curves, areas, and figures of revolution, and we notice the three- and four-cusped hypocycloids, the lemniscate, the kissoid, and other well known curves figuring among the worked-out examples Next follows a chapter on Snellius's law of refraction Some properties of the parabola deduced from the equation of the tangent are next discussed Then follow certain stereometric problems, and in particular an extension of Simpson's rule for the volume of a frustum Each of these sections deals with points which are not satisfactorily treated in existing text-books The book concludes with some interesting problems in spherical trigonometry, in particular the "Heronic" triangle in which the sines and cosines of the sides and angles are rational fractions The book is interesting reading, and quite easy for anyone with an elementary knowledge of the subjects discussed, to follow

"Leçons de Géométrie supérieure" consists of a collection of lecture notes on a course delivered in 1905–6, and transcribed by M Anzemberger The notes are *type-written*, not printed, and we can only wish that a similar method of procedure could be adopted with the mass of dry, uninteresting, superfluous, and wholly irrelevant details which so often occupy pages of printing in modern published "researches" The course can be precisely described to English readers as "solid geometry of curves, surfaces and complexes." It deals mainly with the large subject of curvature, but, in addition to considering systems of lines, the author gives some elegant discussions of systems of spheres and circles. The present reviewer has for some time past given a course of lectures on solid geometry in which the curvature of curves is treated kinematically It is interesting to see this most useful and suggestive method adopted in the present notes, for example, in defining the osculating plane as the plane containing the tangent and the acceleration

M Laurent's book also deals with analytical geometry, mainly solid geometry, but treats principally those portions of the subject which are studied before curvature It has for its object the development of geometry from a purely abstract point of view independently of any preconceived notions regarding space It is thus based on the study of orthogonal transformations and quadratic forms, and an instance of the spirit of the book is afforded by the preliminary note, in which the periodicity of the circular functions is derived from their definition as exponentials apart from any consideration of their geometrical properties The subject-matter includes the study of tangents and envelopes, the properties of surfaces of the second degree, their diameters and polars, the principle of duality, and a final chapter on the non-Euclidean spaces of Riemann and Bolyai The author at the outset advises his readers to make a clean sweep of all their previously acquired geometrical notions It is pointed out that in order to pass from the abstract to the concrete one definition is required, namely, the definition of rigid-body displacement This definition is to be regarded as *fundamental*, and as superseding Euclid's axiom of parallels Among the applications we notice Abel's theorem and an important theorem of Chasles

The story of Abel's life has been told recently in more than one book, yet it is a story that well bears re-telling if for no other reason because it ought to be read as widely as possible It is natural that M de Peslouan should give considerable attention to the part of Abel's life which was spent in Paris, and in a concluding chapter he offers some reflections as to the causes which led to Abel's great memoir being neglected at the time it was offered to the academy To understand these causes, M de Peslouan considers it is only necessary to study the trend of mathematical thought in Paris about the year 1826 At that time French mathematicians were too much engrossed with applied mathematics—such as dynamics and electricity—to give heed to a paper dealing with a property of transcendental functions, and thus nobody understood or appreciated the value of Abel's work The author further cites the parallel case of Galois as another unappreciated mathematical genius who interested himself greatly in Abel's work It might be easy to cite other examples, such as Grassmann The misfortune is that there is nothing to prevent a recurrence at the present time of the circumstances which led to Abel's dying in poverty without obtain-

ing any adequate recognition of the work which in later days caused his name to be handed down to posterity.

Of the remaining two books on our list a great deal might be said, but it would be difficult to give more than a bare statement of their contents in a general review of the present character. Dr. Field's development of the theory of algebraic functions by algebraic methods occupies a useful place in the literature of the subject, and is well adapted for use as an introductory treatise. In the matter of exposition, the summaries at the commencement of each chapter are valuable. The subject-matter includes a discussion of the Riemann-Roch theorem, Plucker's formulæ, and the Abelian integrals. The development of the theory, which is applicable to algebraic equations of the most general character, culminates in the complementary theorem, from which such applications as those just mentioned follow as corollaries.

Prof. Duhem's treatise has for its object the study and analytical expression of the equations of a material medium for displacements and stresses of a more general character than those considered in the ordinary analysis of stresses and small strains. It thus takes account of finite strains and of viscous in addition to elastic resistances. It includes the study of isothermal and adiabatic changes. The problem of wave propagation is discussed at considerable length, and in particular the conditions for permanence of wave motion. Hysteresis is not taken into account. The problem is a generalisation of that dealt with in 1874 by Dr. Oskar Emil Meyer. Some time back a small elementary treatise was reviewed in NATURE dealing with a somewhat cognate subject, namely, the classification of the various phenomena that can exist in a deformable medium, and the present treatise may be conveniently described as an analytical discussion of the x, y, and z equations, while the little book in question explained the A, B, C of the subject.

G. H. B.

OUR BOOK SHELF

Arboriculture Fruitière. By Léon Bussard and Georges Duval. Pp. xii+562, illustrated. (Paris: Baillière et Fils, 1907.)

THE object of this little book, we are told, is to be useful to fruit-growers, and with that view to lay before the reader in a condensed but systematic form as complete a general view as possible of the scientific principles underlying practical methods of fruit culture.

The actual details of cultivation do not differ materially from those followed in this country, but there is a marked difference in the manner, and especially in the spirit, in which the several operations are carried out in the two countries.

Here the details of pruning, pinching, and the like are done in routine fashion, handed down from our predecessors and pursued because experience has shown the utility of the practice.

In France much more thought is given to the matter. The book before us affords an instance of this. The various shapes and positions which the buds assume and the circumstances in which they are formed are gone into with much detail, and we have descriptions of *lambourdes, dards, brindilles, cochonnets, bouquets de mai, chiffons, coursons,* and *bourses* for many of which we have no corresponding terms in English. Nevertheless, a knowledge of these details is essential to a rational system of pruning, and apart from their practical interest they should be carefully studied by those interested in bud variation and "mutation."

We do not think that botanists in general adequately recognise the great diversity that exists in the buds of a single tree. The study of a pear-branch or of a peach-shoot would form an excellent preliminary exercise to the investigation of bud-variation, and perhaps serve to restrain premature theoretical pronouncements. For this reason, apart from its practical utility, we can commend the work before us as well thought out and carefully written. The principal varieties are described, the illustrations are appropriate, there is a table of contents, and an index, the latter not so complete as it should have been.

Physikalische Kristallographie vom Standpunkt der Strukturtheorie. By Ernst Sommerfeldt. Pp. vi+132. (Leipzig: C. Tauchnitz, 1907.) Price 6 marks.

THE title of this book is somewhat misleading. According to the commonly accepted nomenclature of crystallography the book would be described as a geometrical account of the structure-theory with a few physical applications. The ground covered is hardly wide enough to warrant the name "physical crystallography."

The author's style and method are obviously modelled on those of Sohncke. His account of the 230 possible types of crystal-structure is descriptive rather than logical, and will appeal far more to a practical crystallographer who wishes to have some slight acquaintance with modern developments of the structure-theory than to a mathematician who regards the subject as an application of the group-theory. The latter will probably feel a little irritated at the absence of exactness in definition and completeness in proof. For instance, the "space-partitions" on which the argument is based are nowhere clearly defined, and the reason given (p. 65) for assuming fifteen of these partitions as fundamental is quite unconvincing. Surely the partitions should either be limited to the fourteen possible space-lattices or be extended to include such figures as Kelvin's fourteen-walled cell. Sohncke's systems are illustrated by photographs of excellent models, but such diagrams probably convey very little to a reader unless they are arranged for stereoscopic use. The author gives, however, figures showing the projections of these models on a plane which will doubtless be an assistance to the student, though they might with advantage be clearer.

The last forty pages of the book are devoted to a discussion of some physical applications of the structure-theory. Here the author appears at his best, and has some very interesting things to say on the subject of etched figures and rotatory polarisation. His suggestions on etching of low symmetry seem to be new; those on rotatory structure, twinning, &c., are to be found in other books, but the author has brought the argument well up to date. All this part of the treatise is well worth reading, except that in the chapter on crystals with a trigonal axis the real point at issue is a little obscured.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Electrical Method of Extracting Soot from Air in Flues.

ABOUT two years ago I observed that a body positively electrified to 100 volts became covered with soot in a day, while a negatively charged body remained comparatively clean.

I have reason to believe that the observation was first made by Lord Kelvin many years ago, but it does not seem to be well known.

Our laboratory mechanic, Mr. Black, has recently applied this to cleaning air by inserting in an air-flue a sheet of wire gauze connected to the positive 250-volt supply.

The electrified wire gauze is very efficient in extracting the soot from the air, and the method provides a simple means of cleaning the air supplied to large buildings in towns where the air is laden with soot.

Physical Laboratory, The University, Glasgow, April 16.

Paradoxes and Principles.

YOUR critic has written his notice of my "Paradoxes of Nature and Science" (NATURE, February 7, p. 341) without giving reasonable care to the examination of the book, and has in consequence made a damaging statement as to fact which is so extravagantly untrue that it goes far beyond the limits of fair comment.

He says that I neglect general principles in the explanation of paradoxes, and tells me how they ought to be explained, "... by showing that the abnormal phenomena are determined by precisely the same laws as the normal phenomena, to 'explain' why a balloon rises it is necessary to propound the general principles of gravitational mechanics and to show that it rises for the same reason as a stone falls. But Dr. Hampson eschews general principles."

This is grossly untrue. My book teems with statements of and references to general principles "propounded" in explanation of paradoxes, exactly on the system recommended to me. I have not undertaken to explain the rising of balloons—a thing not regarded by me or my acquaintances as paradoxical—but I have explained why water stands in an inverted tumbler, and have done it exactly on the lines prescribed by your critic, propounding, p. 85, the general principle of fluid pressure, "gases, like liquids, are fluids, and transmit pressure equally in all directions. The air, then, transmits in all directions the pressure due to its own weight, and it thus presses upwards beneath ..." and pp. 92, 197, the general principle of gravitational attraction:—"The ordinary meaning of the word 'weight' is an earthward-tending force which can be used as a measure of the quantity of material. It depends upon the mutual attraction between the material and the earth." "... the force ... must vary inversely as the square of the distance in correct agreement with the law of gravitation."

A few of the many other references to general principles invoked in explanation of paradoxes are as follows:—

P. 19, "Heat makes things expand."

P. 29, "It is a general law of nature that a moving body tends to keep moving straight on at the same speed."

P. 32, "... resists ... by virtue of the great law of inertia, the strong tendency possessed by all moving things to resist interference with their motion."

P. 33, "Like all other things, it tries hard to keep to its original direction of movement."

P. 78, "A fluid, when pressed upon ... transmits the full pressure equally in all directions."

P. 93, "... its tendency at any moment is, in accordance with this law of inertia, to go straight on."

P. 97, "... the centrifugal force increases in proportion to the square of the velocity."

P. 116, "The general principle that weights, in descending, cannot produce more power than they consume in being raised the same height."

P. 118, "All things with which we are acquainted have some heat."

P. 149, "The principle that it requires heat energy to convert water into vapour ..."

P. 154, "Gases and vapours are very poor conductors of heat."

P. 170, "The sudden expansion and conversion into vapour require much heat."

P. 179, "The great law of the conservation of energy."

P. 212, "The doctrine that no element could by any means be changed into anything else."

P. 211, The persistence of matter, stated in sixteen lines.

If your critic does not intend to maintain the nonsensical proposition that a book for popular reading by the uninitiated should bristle with quantitative formulæ, how can he say that in writing the above and many dozens of similar passages I eschew general principles? Is this his "idea of scientific method"?

His criticism, as a guess, was, of course, not unlikely to be true of a book for such readers as I had in view. But when a critic has not time to read the book entrusted to him for judgment, would it not be fairer to the journal and to the author if he excused himself from the task of preparing a notice?

Of the value of his criticisms as to style and method, which it would take pages to discuss, I leave your readers to judge by the circumstance that the one statement capable of being definitely tested by a few quotations shows such complete carelessness about facts as to render the critic, if not malicious, certainly incompetent.

February 11. W. HAMPSON.

A SCIENTIFIC "principle" is a proposition assumed to be true universally which is made the basis of deductions. I said that Dr. Hampson "eschewed general principles" in the sense that he does not expound these propositions or make them the basis of his "explanations."

In refutation of this statement Dr. Hampson quotes one paragraph and fourteen short sentences. (The *unquoted reference to p. 211 is not evidence.*) Presumably he considers these passages as convincing as any that he can find; certainly none could be more conclusive of the justice of my criticism. For of the fourteen sentences nine do not deal with principles at all, some of them state non-universal experimental generalisations, others particular cases of general theorems, of which no proof is offered. In the remaining five, two "principles" are mentioned, of which one, the conservation of energy, is merely named, but is nowhere propounded; the other "principle" is Newton's first law of motion.

In order to justify my contention decisively, it is really only necessary to point out (1) that for the last twenty years Newton's laws of motion have not been accepted as adequate principles of mechanics, and (2) that none of the attempts at stating the first of those laws is successful. However, I will make every possible concession and admit, for the sake of argument, that Newton's laws are "principles," and that Dr. Hampson has stated one of them. But then, where are the others? It is impossible to found mechanics on the first law alone. It is just because Dr. Hampson has neglected the second law, which introduces the conception of "force" and all its consequents, that his writings abound in confusion. Thus, in his longer quotation which he holds up as a model of exposition, he has left the imagination of the reader to divine the nature and effects of "pressure" and "force"; it so happens that in this case the ambiguity is not serious, but elsewhere it is extremely serious. It is appalling to think in what mazes he would have entangled himself if he had not been so discreet (but inconsistent) as to omit Pascal's famous hydrostatic paradox from his list.

I repeat, then, that Dr. Hampson has attempted to explain the results of science without enunciating its principles. With fifteen quotations at his disposal he can produce no better evidence against that judgment than four inaccurate statements of a single antiquated principle which was never regarded as a sufficient foundation for even one of the many branches of physics with which he deals!

THE REVIEWER.

EROSION AT NIAGARA.

IT seems to have been a matter of common observation among the early colonists of America that the Niagara Falls had receded from the escarpment at Queenston to their present position six miles up the gorge. In spite of the view then frequently held that ravines were to be accounted for by violent rendings of the crust, those six miles, even in the eighteenth century, were appealed to as a natural time-scale. It was, moreover, felt that the rate of recession might give us a measure of the antiquity of the earth. James Hall in 1842 established a series of marks and monuments to which subsequent surveys might refer, and Mr. G. K. Gilbert[1] now draws conclusions from the work of his predecessors in 1842, 1875, 1886, and 1890, and from Mr. W. C. Hall's re-examination of the edge for the United States Geological Survey in 1905. He reproduces some of Captain Basil Hall's drawings, made with a camera lucida in 1827, and interesting photographs taken from 1855 onward. The former, which appear to be of great accuracy, throw doubt on certain details of the map of 1842. Mr. Gilbert regards the survey of 1905 as of especial importance, since it is the last record of the Niagara River in a natural condition. "The Erie Canal is supplied with water from the Niagara River at Buffalo, the Welland Canal is supplied from Lake Erie, and the Chicago Drainage Canal draws water from Lake Michigan. All the water thus diverted is withdrawn from the cataract. So also is the water diverted from the river above the falls for factory purposes and for use in the generation of electricity" (p. 12).

The Horseshoe, the true head of the Niagara Gorge, about 1886. The notch in the farther margin was not present in 1827.

The really active line of erosion is at the lip of the Horseshoe Fall. Very little recession occurred here at the head of the gorge between 1827 and 1842, but the rate between 1842 and 1875 was about 4 feet per annum, and from 1875 to 1905 nearly 6 feet per annum (p. 15). "The distance through"—Mr. Gilbert writes "thru"—"which the Horseshoe Fall has retreated since it parted from the American Fall is about 2500 feet. Allowing 5 feet per annum as the rate of recession, the parting took place about five hundred years ago." The present average rate of recession of the American Fall is probably only 0.2 foot per annum.

Mr. Gilbert, in view of the importance of local and temporary conditions, such as the position of joints in the limestone shelf, wisely makes no estimate of the time that has elapsed since the falls occurred at Queenston. But his study will be welcome in the literature of geology and geography alike, since it deals with one of the most famous types of river-erosion in the world. G. A. J. C.

1 "Rate of Recession of Niagara Falls." By G. K. Gilbert, accompanied by a Report on the Survey of the Crest by W. Carvel Hall. Pp. 31+11 plates. (Bull. U.S. Geol. Survey, No. 306, 1907.)

A YEAR'S WORK OF THE CARNEGIE INSTITUTION.[1]

THE Carnegie Institution was founded, and endowed with 2,000,000l., in order "to encourage, in the broadest and most liberal manner, investigation, research and discovery, and the application of knowledge to the improvement of mankind." The year-book for 1906 contains a general report on the work of the year, and short abstracts of the special investigations in progress. To the reader it affords abundant opportunity of "fine confused feedin'", to the reviewer a mass of projects and results of which it is hopeless to give any adequate account.

The trustees' plan of campaign has not yet been thoroughly worked out, and, indeed, in detail at least, must vary with the time. At the outset they had hosts of applications for assistance in research. The universities and colleges of the United States are now largely staffed by men brought up on research, who find themselves without the time or the appliances for the work they have prepared themselves to do. It was natural that they should appeal to the institution for assistance and that the trustees should respond by making grants in aid to individual investigators on a somewhat extensive scale. But difficulties have made themselves manifest, especially in the supervision of miscellaneous investigations, and experience has convinced the trustees that there is a greater prospect of a valuable return from large projects carried on under the direct supervision of the institution than from minor projects entrusted to individuals. Accordingly, during 1906, while the larger projects have been increased, a smaller number of minor grants have been made than in former years.

There are at present forty-five of these minor projects in progress. They are for the most part researches in mathematical, physical, and natural science and in history, literature and philology, but they include also the preparation of such works as the "Index Medicus." The grants in aid of them range from 50l. to 2000l., and seem to be made for the provision of assistants, apparatus and materials, and for the publication of results. The total amount thus allotted during the year was about 19,000l.

The larger projects may be divided into four classes—astronomical, geophysical, biological, and economic and historical. Astronomy has always been

1 Carnegie Institution of Washington Year Book No. 5, 1906. Pp. viii+266. (Washington: Published by the Institution, 1907.)

a favourite researching ground in America Few of its larger universities are without observatories, and many of the smaller colleges possess them also The institution seems to aim at extensive schemes which are beyond the scope of the universities In the department of solar physics 28,000*l* has been expended on the buildings and equipment of the Mount Wilson Observatory, and the year's work under Prof Hale includes photography of the sun and of the spectra of sun-spots and flocculi, spectroscopic study of solar rotation, and bolographic study of solar absorption It is interesting to note that, notwithstanding its princely endowment, the institution is glad to announce a gift of 9000*l* for the provision of a mirror of 100 inches aperture for a great reflecting telescope, to be used for the analysis of the light from faint stars and nebulæ The second astronomical department, that of meridian astronomy, has been organised in the present year, and Prof L Boss has been appointed, with an appropriation of 40,000*l*, to superintend the preparation of a catalogue giving the precise positions of all stars down to the seventh magnitude As an essential feature of the work he is to establish a temporary observatory in the southern hemisphere

In the department of geophysics, the work has been conducted hitherto by individuals But their investigations on the flow of rocks, the elasticity and plasticity of solids, and mineral solution and fusion under high temperatures and pressures, have been so successful that an appropriation of 30 000*l* has been made for the purchase of a site in Azadia D C, and for the building and equipment of a laboratory In another geophysical department, that of terrestrial magnetism, Dr L A Bauer, with a grant of 11,000*l*, has been carrying out a magnetic survey of the Pacific Ocean, as well as of the island of Hainan and a number of islands of the southern Pacific

There are five biological departments The widest in scope is that of experimental evolution, under the direction of Prof Davenport, who has been provided with a laboratory specially designed for the study of the phenomena of heredity hybridisation, and mutation, "by substantially the same methods as those applied to the stars by the astronomer or by the chemist to inorganic matter" The director is hopeful of success, and has already some results to report, but he points out that "a decade is the smallest convenient unit of time for measuring the progress of the more important investigations now under way" The department of marine biology is under the direction of Dr A G Mayer, who has been provided with vessels, buildings, and docks and with the aid of specialist guests is studying the fauna of the Florida coast More novel in its aim is the department of desert botany, which has a domain and buildings in Arizona, and is directed by Dr D T MacDougall It is devoted to research on the flora of arid regions, and the influence of altitude and climate on vegetation The director is establishing small plantations at various heights above sea-level, and denuding areas here and there that he may study their re-occupation by desert plants He is also making systematic observations on the shores of an accidentally formed lake 500 square miles in area in the Salton Basin, California The channel between the lake and the Colorado River, by the overflow of which it was formed has now been closed, and during the gradual disappearance of the lake the re-occupation by desert vegetation of the areas left bare by the recession of the water is to be studied

The department of horticulture is on more ordinary lines, plant, flower, and fruit development forming its scheme of work The department of nutrition is less conventional in its character, its aim being to extend our knowledge of the physics and chemistry of normal nutrition and of the conditions and remedies for abnormal nutrition As in previous years, its work is entrusted to individual investigators —three, working on distinct lines—at whose disposal a sum of 3000*l* has been placed, but the provision of a special laboratory is under consideration [1]

Finally, we have the related departments of historical research and of economics and sociology Prof J F Jameson, who directs the former, is engaged mainly in the preparation and publication of guides to the materials for American history to be found in the archives of Washington, Cuba, Great Britain, and Spain, to be extended as soon as possible to France, Mexico, and Rome, also in the publication of documents bearing upon the history of the United States About 3000*l* has been allotted to this department during the year In economics and sociology, Dr C D Wright and his 130 collaborators, with a grant of about 6000*l*, have been making a bibliographic index to the public documents of the various States of the Union, and are studying population and immigration, agriculture and irrigation manufactures, transportation, labour and industrial movements, taxation, and the negro problem, with a host of questions which these subjects suggest, ranging from railway pools to the need of church federation in Vermont

It will be noticed that in the selection of larger projects the trustees have kept in view Mr Carnegie's expressed wish that not merely knowledge itself, but the application of knowledge to the improvement of mankind should be advanced Most of the departments which have been organised have a distinct practical bearing, and some, such as the desert botany and the terrestrial magnetism departments, have blocked out work of great importance from both points of view That the "mankind" of the articles of incorporation is being interpreted in the first instance in a somewhat local sense is natural Charity begins at home And it must be remembered that we are all interested in the ocean magnetic fields in which the great Republic has a special interest that we must all benefit by a thorough knowledge of the history and the social condition of the United States, and that year by year we are all becoming more painfully affected by those abnormalities of nutrition to which the strenuous life of her citizens is supposed to give rise

Little space remains to notice another department of the work of the institution, viz the issue and distribution of publications So far, fifty-seven volumes have been published, and thirty-one are now in the press During 1906 nineteen volumes appeared, the expenditure on them being about 8500*l* Lists of the publications are sent to about 10,000 individuals and institutions, but as the standard edition is 1000 copies only, but one-tenth of the 10,000 can be expected to respond This restriction to 1000 copies is the most un-American feature of the policy of the institution, and in the interests of the advancement of knowledge is to be regretted. No doubt even an endowment of 2 000,000*l* gives a limited income But if the scientific work which it produces is of value, the publications describing the work should be widely distributed And the president seems to take a perverse view of the question when, in order to meet anticipated criticism, he says:—"If the bibliophile has found reason for dissatisfaction in the distribution of the publications of the Institution he may be disposed to be lenient with the latter on learning that he is one of many thousands soliciting favors"

[1] Since the issue of the Year Book it seems to have been decided upon

AËRODYNAMICAL EXPERIMENTS AND OBSERVATIONS IN RUSSIA

THE results of an extensive series of experiments upon the resistance of various forms of bodies in a current of air, as well as the particulars relating to various balloon ascents and observations upon the height of clouds, are given in two publications recently received from the Institut aérodynamique de Koutchino.[1] The institute (Fig. 1) was founded for the purpose of studying air resistance and for the scientific exploration of different layers of the atmosphere. Besides the director and honorary members of the staff, there are in all twenty-one men employed, of whom six are labourers.

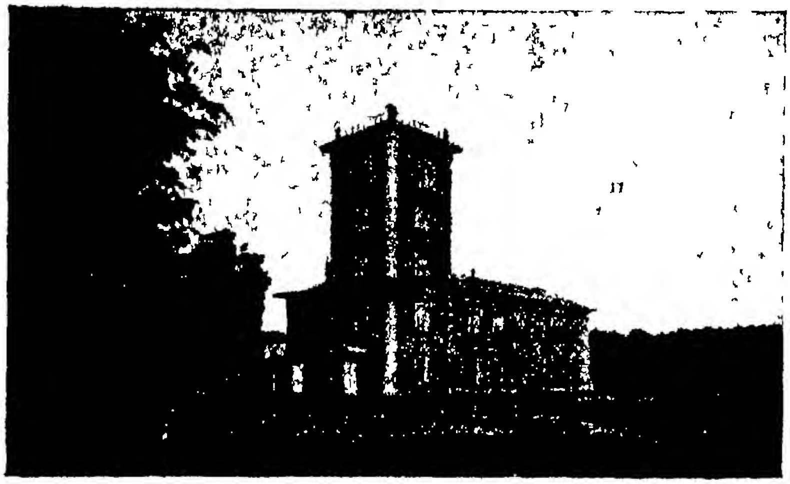

FIG. 1.—The Aërodynamic Institute at Koutchino.

The buildings and equipments cost 100,000 roubles. There is a dwelling house for the staff, a hall, 100 feet by 43 feet by 28 feet, for experimental work, and suitable workshops and tools.

The experiments upon air resistance were made in a long cylindrical tube 48 feet long and 4 feet diameter, shown in Fig. 2 (a piece of the tube is temporarily removed to show the position of a small screw inside). The air current in this tube is produced by an electric fan, the power coming in the first place from a thirty horse-power steam engine. It was found at first that the air current in the tube was not uniform, and was not even symmetrical about the axis of the tube, since greater proximity to the floor and one wall of the building produced a disturbing effect. This difficulty was overcome by inserting the end of the tube into a large cylinder 7 feet diameter and 12 feet long. The velocity of the air in the tube was carefully measured for various speeds of the fan, and subsequently the velocity for each experiment was obtained from the number of revolutions of the fan.

The weak point of this method is that the body which is being experimented upon in the tube presents an obstacle to the free motion of the air, and therefore reduces the velocity, and furthermore, the walls of the tube exert an unknown influence upon the result excepting for quite small bodies placed near the centre. With a similar arrangement at the National Physical Laboratory, Mr. Stanton found that working with a tube of 2 feet diameter he could not experiment upon a pressure plate of more than 2 inches diameter without finding that his results were vitiated by the influence of the walls of the tube.

It is impossible in a brief notice to give an account of all the experiments; perhaps the most important are those showing the increased lifting power which a screw possesses when a current of air is made to blow at right angles to its axis. Thus the lifting power with a horizontal current of 20 feet per second was found to be more than twice as great as with still air, although the driving power required was not increased.

Details of the methods and results of four ascents of unmanned balloons are given, and it is noteworthy that in a country like Russia the instruments should be so often recovered.

FIG. 2.—Tube for Experiments on Air Resistance at the Aërodynamic Institute, Koutchino.

The observations on clouds depend on the use of an electric search-light, and the observation, by a theodolite in the neighbourhood, of the position of the patch of lighted cloud. Unfortunately, the method can only be pursued at night, when the type of cloud is not very easy to determine.

[1] Institut aérodynamique de Koutchino (St. Petersburg, 1905.) Bulletin de l'Institut aérodynamique de Koutchino, Fascicule I. (St. Petersburg: Golicke and Willborg, 1905.)

The whole account will well repay a careful perusal, and anyone engaged on the design of a flying machine will find much useful information in the results of the various experiments on bodies rotating in a current of air

THE MEXICAN EARTHQUAKE

ANOTHER great earthquake has been added to the series which has marked the recent increase in seismic and volcanic activity along the Pacific coast of America At 11 30 p m on Sunday, April 14, or about 6 a m of April 15 by Greenwich time, the greater part of Mexico was visited by a destructive earthquake As usual, the first accounts were not only exaggerated, but gave an erroneous impression of the distribution of damage, Mexico city, which was represented as almost destroyed proved by later accounts to have been comparatively little damaged, while the towns of Chilpancingo and Chilapu, as well as some others not to be found in ordinary atlases, suffered great destruction The sea-coast towns from Salina Cruz to Acapulco suffered severely, and a portion of the latter is said to have been submerged The shock is reported as severe at San Luis Potori and Juan Batista though no damage was done at either place, these two cities are about 530 miles apart and about 350 miles from the region of greatest damage, so we may estimate the area over which the shock was sensible as extending to somewhere about 500 miles from the centre of the disturbance

The earliest reports stated that railway communication between Mexico city and Vera Cruz was suspended owing to the sinking of the permanent way, but this news, which has not been corroborated in later telegrams, is the only suggestion that the focus of the earthquake may have extended to any distance from the west coast Everything else points to the conclusion that it originated close to the shore-line of the Pacific, and was partly, if not wholly, submarine Sea-quakes are common in this region, sometimes they are felt by ships at sea though unnoticed on shore, and in at least one instance seem to have caused the loss of a ship The story is a remarkable one On October 3, 1902, the German barque *Freya* cleared from Manzanillo for Panta Arenas, nothing more has been heard of the captain or crew, but the ship was found twenty days later, partially dismasted and lying on its side There was nothing to explain the condition of the ship, but a wall calendar in the captain's cabin showed that the catastrophe must have overtaken it on October 4 not long after leaving port, as was also indicated by the anchor being found still hanging free at the bow Weather reports show that only light winds were experienced in this region from October 3 to October 5, but on the other hand, severe earthquakes were felt at Acapulco and Chilpanzingo on October 4 and 5 one of which probably caused the damage to the *Freya* which led to its abandonment

Prominence has been given in the daily papers to earthquakes in Spain and Italy, which occurred shortly after the Mexican one; but they were of an order the occurrence of which is too frequent to justify any direct connection between them and the greater one It may be different as regards the other two large earthquakes, which were registered at 9 10 p.m on April 18, and at 0h 11 a m on April 19, no news of these shocks has yet reached us, they must have been earthquakes of the first order of importance but are only known from distant records which are interpreted as showing that they originated at about 90° from western Europe This is about the distance of Mexico, but it is rare for after-shocks to be of as great magnitude as these; on the other hand, it is not uncommon for earthquakes to take place in groups, usually originating at nearly opposite points in the globe We may consequently, in the absence of news of a great earthquake in America or Japan, look for the origin of these two earthquakes in the North Pacific Ocean on the eastern part of the Malay Peninsula.

TUBERCULOSIS RESEARCH AND VIVISECTION

THE investigations conducted by the Royal Commission on Tuberculosis, contained in a second interim report recently issued,[1] would have been impossible without the use of experiments on animals, and the appearance of this report is most opportune, for, almost simultaneously, the Royal Commission on Vivisection has published the first volume of the minutes of evidence taken before it

As regards the investigations on tuberculosis, thirty different viruses isolated from cases of tuberculosis occurring spontaneously in bovines have been studied, and the results of introducing them into a number of different animals by feeding and by inoculation are recorded In calves, inoculation usually results in generalised progressive tuberculosis, but the effect is somewhat dependent on the dose, *i e* the number of bacilli administered Feeding, on the other hand, usually produces lesions limited to the neighbourhood of the digestive tract, which generally retrogress and become calcareous The bovine bacillus, when introduced into rhesus monkeys or chimpanzees either by inoculation or by feeding, induces rapid generalised tuberculosis, and considering the close relation that exists between the anthropoid apes and man, these results are of the highest importance In pigs generalised progressive tuberculosis is readily set up both by feeding with, and by the inoculation of, bovine bacilli Goats, dogs, and cats are relatively less susceptible, but more or less tuberculous infection can similarly be produced in them On this part of the investigation the commissioners remark that the bacillus of bovine tuberculosis is not so constituted as to act on bovine tissues only, and the fact that it can readily infect the anthropoid apes, and, indeed, seems to produce this result more readily than in the bovine body itself, has an importance so obvious that it need not be dwelt on

The viruses isolated from sixty cases of the disease in man have also been studied, and the results obtained show that they may be divided into two groups, subsequently referred to as group i and group ii The bacilli of group i were mostly obtained from cases of abdominal tuberculosis occurring in children, and the results produced by introducing them into animals are identical with those produced by the bovine bacillus The bacilli of group ii, obtained from various forms of human tuberculosis, grow more luxuriantly in culture than those of group i, and inoculated into calves and rabbits do not produce the generalised and fatal disease caused by the bovine bacillus, but in rhesus monkeys and in the chimpanzee set up a general tuberculosis Certain human viruses, differing in certain respects from those of groups i and ii, were also met with, and are classed as group iii, but an opinion on their significance is reserved for a future report

The commissioners conclude that the tubercle bacillus in its nutritive and reproductive powers re-

[1] Second Interim Report of the Royal Commission appointed to inquire into the Relations of Human and Animal Tuberculosis, Part I., Report Part ii, Appendix, Vol. iv, "Comparative Histological and Bacteriological Investigations." By Dr Arthur Eastwood

sembles other simple organisms, and that the essential difference between one strain and another depends on variations in these factors, and they therefore classify the bacilli as *dysgonic*, those that grow with difficulty on artificial media, and as *eugonic*, those that grow readily on the same media

The bearings of the results obtained are thus summarised:—

"There can be no doubt that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis, and that in the majority of these cases the disease is introduced through cow's milk Our results clearly point to the necessity of measures more stringent than those at present enforced being taken to prevent the sale or the consumption of tuberculous milk" The details of the various experiments are published in the appendix, in which Dr Eastwood gives a full description of the histology of the lesions in the various animals inoculated, and of the bacteriology of the bacilli isolated from them, together with the methods employed This appendix is a volume of 300 pages, illustrated with tables and charts, and must rank as a first-rate piece of work Dr Eastwood concludes that there is an essential unity, not only in the nature of the morbid processes induced by human and bovine tubercle bacilli, but also in the bacteriological characters of the tubercle bacilli which cause these processes

As regards the minutes of evidence taken before the Vivisection Commission,[1] the witnesses so far called include Mr W P Byrne C B, who discussed the procedure of the Home Office in the granting of licences and in the administration of the present Act, Mr G D Thane Sir J Russell, and Sir W Thornley Stoker, the official inspectors under the Act, Mrs K Cook and Dr Snow, representing anti-vivisection associations, Mr Stockman, chief veterinary officer of the Board of Agriculture, and Prof Starling

As already suggested, the work of the Royal Commission on Tuberculosis, reviewed above, affords one of the most striking examples of the necessity for, and of the value of, experiments on animals, and the evidence so far given before the Vivisection Commission has brought out the fact of the scrupulous observance of the conditions of their licences by the various holders of the same, of the complete absence of that cruelty and callousness for which the experimenters have been assailed by those who advocate the abolition of vivisection, and of the absolute necessity for the experimental method in the medical and biological sciences if these are to advance The inspectors seem agreed that there is no need for more inspection in order to check abuses Surprise visits can be, and are paid at any time, and what each worker is doing is known to the Home Office

NOTES

The absence of official representatives of the British Government at the celebrations connected with the opening of the Carnegie Institute at Pittsburg formed the subject of questions asked in both Houses of Parliament on Monday The replies were to the effect that our Ambassador to the United States was prevented by other engagements from attending the celebrations, and Lord Fitzmaurice added —"I am exceedingly glad of the opportunity publicly to state how much His Majesty's Government, and our Ambassador at Washington, appreciate the importance of that occasion" In his explanation to the House of Commons Mr Runciman said —"Neither the German, Austro-Hungarian, French, nor Russian Embassies were represented at Pittsburg It is understood that the Universities of Oxford and Cambridge were represented at the celebrations at Pittsburg, and on such an occasion the presence of members of the greatest educational institutions of the country would appear to be the form of representation most suitable and convenient" The explanations do not appear to us to be entirely satisfactory That representatives of British universities were present at Pittsburg is not a circumstance for which the Government can claim any credit If these guests of Mr Carnegie had been asked to represent the Government on the occasion the case would have been different, but no official notice was taken of them or of the event When every allowance has been made, the fact remains that the German Emperor took advantage of an opportunity to show his interest in the advancement of knowledge, and that the British Government failed to do so

A MEDALLION in memory of the late Pierre Curie, by M Vernier has been placed on the wall of his laboratory at the Ecole municipale de Physique et de Chemie, Paris

ON May 6, 8 and 10, Prof W Wright will deliver three Hunterian lectures of the Royal College of Surgeons on "The Prehistoric and Early Historic Inhabitants of England"

DR G O SMITH has been appointed director of the U S Geological Survey to fill the vacancy caused by the election of Dr C D Walcott to the secretaryship of the Smithsonian Institution

ON Saturday next, May 4, Prof W C McIntosh will begin a course of two lectures at the Royal Institution on "Scientific Work in the Sea Fisheries" The Friday evening discourse on May 3 will be delivered by Sir James Crichton Browne on "Dexterity and the Bend Sinister" and on May 10 by Signor Comm Giacomo Boni on "Recent Excavations on the Forum Romanum, and the Forum Ulpium"

THE death is announced, on Saturday April 13, of Mr C L Griesbach C I E formerly director of the Geological Survey of India Born in Vienna on December 11, 1847, he was educated in the university of that city Afterwards coming to England, he was appointed to the Geological Survey of India in 1878 made director of it in 1894, and retired from the post in 1903 His most important geological work was done beyond the frontiers of British India, and especially in Afghanistan which he visited first with the Canadian field force in the Afghan war, again with the Afghan Boundary Commission in 1884–6 and for a third time as adviser to the Amir in 1888–9 His descriptions are still the only available sources of information regarding the geology of much of the country seen by him on these occasions The popular idea that a desire to avoid military service is the reason why foreigners settle in this country, was not borne out by Mr Griesbach who joined the British Army shortly after his arrival in England, saw active service in Candahar, was mentioned in despatches earned war medals and clasps, and was made a C I E for his services with the Afghan Boundary Commission

WE regret to learn of the death on Saturday last, of Mr George E Davis, the founder and editor of the *Chemical Trade Journal* Mr Davis was one of the original fellows, and subsequently a member of council, of

[1] Royal Commission on Vivisection Appendix to First Report of the Commissioners. Minutes of Evidence, October to December, 1906.

the Institute of Chemistry, a fellow of the Chemical Society, and he took a prominent part in the inauguration of the Society of Chemical Industry, filling in succession the offices of honorary secretary member of council, chairman of the Manchester section, and vice president Mr Davis contributed largely to chemical, technological, and microscopical literature His "Handbook of Chemical Engineering" was published in 1901, and his other collected works include "Sizing and Mildew in Cotton Goods" (written in conjunction with Dr Dreyfus and Mr Philip Holland) "The River Irwell and its Tributaries" (of which he was co-author with his brother, Mr Alfred R Davis), and numerous other miscellaneous pamphlets, lectures, &c From its commencement in 1887 he acted as editor in-chief of the *Chemical Trade Journal* Mr Davis was in his fifty-seventh year

AFTER a sojourn of nearly a quarter of a century in Brazil, Dr E Goeldi has felt it necessary to resign the directorship of the museum which now bears his own name at Pará He is succeeded by his colleague, Dr J Huber, who has hitherto had charge of the botanical section The State Government of Para has issued an appreciative notice of Dr Goeldi's services in connection with the museum

WE have received a copy of the *Photographic Monthly* for April, which contains reproductions of Mr J P Millar's photographs of young cuckoos in the act of ejecting their fellow-occupants of nests Most, if not all, of these pictures have already appeared in a little work by Mr W P. Westall which has been noticed in our columns

THE aphides of the genus Chermes infesting conifers in Colorado form the subject of the first article in the Proceedings of the Philadelphia Academy for the current year Several species occur which have life histories of the same general type as that of the European *Chermes abietis*, both hibernating and migratory females being produced New and other orthopterous insects from Arizona are described by Mr J A G Rehn in the second article

Two important articles are contained in the issues of *Biologisches Centralblatt* for March 15 and April 1, the one by Dr Max Wolff, on the spinal cord of the lancelet, and the other by Mr A Mordwilko, on the biological relationship existing between ants and plant lice In the former attention is specially directed to the morphology and genesis of the cord, certain very remarkable conclusions being reached with regard to the origin of its central canal The nature of "symphilism" and its relation to parasitism is discussed in the latter

AMONG the contents of vol xli, part iii, of the *Journal of Anatomy and Physiology*, special reference may be made to an article by Messrs A Keith and M Flack on the form and nature of the muscular connections between the primary divisions of the vertebrate heart One of the most important conclusions relates to the existence in mammalian hearts of a remnant of primitive fibres at the sino-auricular junction These fibres, which are intimately connected with the vagus and sympathetic nerves, have a special arterial supply and it is in them that the dominating rhythm of the heart is believed normally to arise Considerable interest also attaches to the description, by Mr G A Hill, of a female skeleton, apparently referable to the Bronze age, from a cave in Littondale, Yorkshire

IN discussing polygamy and other mating habits among birds in the March number of the *American Naturalist*, Dr R W Shufeldt refers to the imperfection of our knowledge on this subject in the case of many groups, stating for example, that he cannot find out whether kiwis and brush-turkeys are polygamous or monogamous. Although birds may be polygamists, monogamists, or in certain conditions given to practices similar to polyandry, or even, possibly, to polyandry itself, we have no information with regard to the origin, causes, and, in most instances, the needs of these divergent habits It is, however, more easy in many cases to explain the radical changes which take place in these respects as the result of domestication It may be added that the author disbelieves in the existence of any close relationship between kiwis and other struthious birds, or between the latter and tinamous "A kiwi (Apteryx)," he writes, "is no nearer an ostrich, and an ostrich to a tinamou, than a limpkin (Aramus) is to a bustard, and a bustard (Otis) to a quail (Colinus)"

IN the April number of the *Quarterly Review*, Prof J C Ewart, of Edinburgh, discusses recent opinions and theories relating to the origin of the modern horse After reviewing the early history of the horse-stem (throughout which the name Protorohippus is misspelt Proterohippus) the author states that he recognises three equine types as having existed in Europe about the close of the Glacial type, namely, the steppe, the forest, and the plateau type Without entering into the consideration of all the characteristics of these it may be mentioned that, according to the evidence of skulls from a Roman fort at Newstead the forest type is distinguished by the face being placed nearly in the plane of the basicranial axis, whereas in the steppe type (to which the Mongolian Przewalski's horse is stated to conform, if, indeed, it be not the exemplar) the former is sharply bent down at an angle to the latter According to the author, the skull of the celebrated thoroughbred "Stockwell" conforms very closely in this respect to the steppe type, and is altogether different from the plateau or Libyan type, although agreeing with the latter in the characters of the cervico-dorsal vertebræ If such mixed features really exist in one and the same skeleton, there would seem little hope of an early settlement of the problem of the origin of the thoroughbred

A MEMOIR on "Variation and Correlation in Ceratophyllum," by Prof Raymond Pearl, with the assistance of Miss O M Pepper and Miss F J Hagle, has been published by the Carnegie Institution of Washington The memoir deals, on somewhat novel lines, with the variation in the number of leaves to a whorl (and other characters), with especial reference to the laws of growth It is shown that the mean number of leaves to a whorl y is related to the ordinal position of the whorl from the base of the branch x by a relation of the form $y = A + B \log (x - C)$, the mean increasing rapidly at first and then more slowly For a branch of a given order the constant A alone varies in populations from different environments, *i e* the means vary but not the form of the law by which the successive whorls are differentiated In branches of successive orders the constant B tends to increase, the mean number of leaves to a whorl tending towards the final limit with greater rapidity in secondary as compared with primary branches The variability of the whorls decreases from the base of the branch onwards, successive whorls being produced "with ever-increasing constancy to their type, the ultimate limit towards which the process is

tending being absolute constancy," and an analogy is drawn between this law and the perfection of an action by repetition or practice The author believes that both laws are of considerable generality, and apply to other organisms

WRITING on the anti-opium drug in the Journal of the Federated Malay States Museums (December, 1906) Mr L Wray identifies the plant as *Combretum sundaicum*, and describes the method of making an infusion from the roasted twigs and leaves This is mixed with a decoction of burnt opium and it is possible that the latter supplies part of the curative effect In the same number Mr H C Robinson contributes a list of the birds found on the Aroa Islands, in the Straits of Malacca

REFERENCE is made to a new klinostat—the instrument used to counteract the influence of gravity—designed by Dr P van Harreveld in *Recueil des Travaux botaniques Néerlandais*, vol iii The author tested several instruments by means of an automatic chronograph device from which he concluded that a periodic irregularity could always be detected This is important, since the repetition of a very weak stimulus at regular intervals is cumulative and will in time induce curvature The essential features of the author's klinostat are that it is weight driven, the impulses being suitably moderated and regulation is effected by independent electromagnetic mechanism

IN his report for the year 1905 Mr J H Maiden the director of the botanic gardens and public domains Sydney, New South Wales, announces that the changes connected with the re grading of the botanic garden have been completed after five years' work Reference is made to the work of a previous director, Mr Charles Moore who died during the year Among the Australian garden plants that attracted attention when flowering were *Thymalium Billardieri* *Euroschinus falcatus*, and *Kennedya procurrens* the last being a new introduction of New South Wales origin

AN article by Mr R S Pearson on the level of sub-soil waters with regard to forests is published in the *Indian Forester* (February) Comparing the levels inside and outside forests, they are always higher outside, in an area of low rainfall the difference of levels is greater than where the rainfall is more abundant, and the level is steadier inside than outside the forest These results are explained by the facts that the trees intercept a portion of the rain water and make a heavier demand on the water supply than agricultural crops Sir Dietrich Brandis contributes a note on *Mastixia euonymoides*, with a figure of the stem section and Mr B O Coventry supplies photographs of the Changa Manga plantation in the Punjab, showing the cultivation of the *shisham* tree *Dalbergia Sissoo*

IT has been shown by Prof G Klebs that remarkable metamorphoses can be produced in plants by artificial methods of cultivation His latest contribution that was published in the *Abhandlungen der naturforschenden Gesellschaft*, Halle (vol xxv), gives some account of the results that he obtained Four species of Sempervivum were selected for experiment, because abnormality of structure has rarely been recorded for the genus The method consisted in removing the terminal inflorescences from plants that had been stimulated by heavy manuring or exposure to strong sunlight, when lateral flowers or inflorescences showing intense variation were developed Irregularities in number and shape of the parts of the flower, changes from one part to another, and vegetative developments occurred, perhaps the most striking being the combination of staminal and carpellary structures These and experiments with *Veronica chamaedrys* and other plants lead the author to the opinion that new *races* can arise as a result of changes in external conditions

FROM a second memorandum on the American gooseberry mildew (*Sphaerotheca mors-uvae*), just issued by the Board of Agriculture and Fisheries, we learn that during the winter of 1906–7 the presence of the mildew in certain gardens in Worcestershire was definitely confirmed and the cases investigated under the auspices of the Worcestershire County Council Reports sent to the Board have shown that the extent and seriousness of the disease are much greater than was at first supposed and in view of the increased danger of infection which arises when the mildew passes into its summer stage the Board advises all gooseberry growers to watch the plants closely during the summer months, especially those bushes which have been recently bought in order that the disease may be detected and dealt with at the earliest possible moment Gooseberry growers who have the least reason to suspect infection are advised to spray their bushes with a solution of liver of sulphur (potassium sulphide) from the time the leaves open until the fruit is set A solution of half an ounce to a gallon and a half of water is recommended for the first spraying and the strength should be increased to a solution of half an ounce to one gallon of water at the second spraying Details as to the examination and treatment of plants in order to prevent the spread of the disease are given in the Board's new circular, which can be obtained post free on application

THE Bulletin of the Manila Weather Bureau for August 1906 contains a reproduction of what is probably the only complete seismogram of the Valparaiso earthquake in existence The distance from the centres of the North Pacific and Chilian earthquakes of August 17 was such that the disturbance due to the former had practically died out before the arrival of the latter the first preliminary tremors commenced at 1h 13m Greenwich time and lasted until about 1h 21m The instrument being a Vicentini microseismograph with a vertical pendulum of 1.5 metres length, the third phase waves which give the greatest amplitude with a slow-period horizontal pendulum, are of small size, and it is largely due to this that the earlier phases of the record of the Valparaiso shock are so little complicated by the end portion of the preceding one

THE Geological Survey of Western Australia has issued another report (Bulletin No 24) of the special series dealing with different mineral fields of the State The report, which covers seventy-nine pages and the accompanying thirteen maps and twenty-six plates, represent the results of the work of Mr C G Gibson in the Laverton, Burtville and Erlistoun auriferous belt Mt Margaret Goldfield In Bulletin No 25 Dr R Logan Jack discusses the prospects of obtaining artesian water in the Kimberley district, Western Australia He passes in review nine distinct areas in which he anticipates more or less success in the search for artesian water

THE richness and complexity of its deposits have given to mining in the Cobalt district of Canada special interest and much valuable information regarding this new silver-mining district is contained in an admirably illustrated article by Mr J F Hardman in the *Engineering Magazine*

(vol xxxiii, No 1) The first discovery of silver was made in the district in July, 1903, and the progress made since that date is described in detail The characteristic rocks of the region are conglomerates of Lower Huronian age, through which, and sometimes through the underlying diabase, pass calciferous veins carrying metallic silver and sulphides or arsenides of silver with smaltite and niccolite, the arsenides of cobalt and nickel The veins occur along the main lines of fracture by which the conglomerate has been shattered As to the permanency of the deposits very different opinions have been expressed, but with increasing experience the trend of opinion is towards a long life for the district

IN addition to the usual record of measurements taken during the year 1906 at Epsom College, the report of the college Natural History Society for last year gives the average height, weight, and chest girth of all boys who have been measured in the ten years 1897–1906, and a chart showing average grades of development for the same period On the whole the average Epsom College boy would appear to be rather superior in physique than inferior to the average public-school boy One marked exception is evident in the curves for the ages 17 yr 10 mo to 18 yr 4 mo though it must be stated that the number of observations on which the curves are based is, for these months much smaller than the rest Boys at Epsom College between these ages however during the last ten years appear to have been on a lower physical grade than at other ages The other contents of the society's report show that excellent field work continues to be done by the members, among whom geology, botany and meteorology appear to be equally popular

THE subject of the perception of relief was discussed in letters to NATURE of January 3 and 31 last (vol lxxv pp 224 and 321), and the same question is raised in a communication received from Mr R T A Innes of the Transvaal Meteorological Department Mr Innes describes a method of seeing stereoscopic pictures in relief without the use of a stereoscope explained to him by Colonel W G Morris If while steadily viewing a distant object an index finger be held before the eyes, two images of it are seen if now the other index finger be held before the eyes also, four images will be seen By a little adjustment of the distance of the fingers from the eye the two central images can be superposed The substitution of a stereoscopic picture leads to similar results, and the superposed images give the idea of relief

MR F A LINDEMANN and Mr C L Lindemann writing from Darmstadt, describe a new glass which is transparent to rays of very short wave-length They have found that lithium biborieum, $Li_2B_4O_7$ (ordinary borax in which the sodium is replaced by lithium), when fused produces a clear glass which shows no appreciable absorption in the ultra-violet spectrum above 2000 Å The aluminium line 1856 is distinctly visible, though somewhat weakened if the glass be too thick In order to determine the absorption below this a vacuum spectrograph would naturally be required, as the air absorbs any lines shorter than 1856 The refractive index for the D-line $n=1\ 5389$ the dispersion Δ between c and F, $\Delta=0{\cdot}00847$, and $\nu=n-1/\Delta=63\ 7$ As might be expected, owing to the large percentage (82 5) of boracic acid, the dispersion toward the red side of the spectrum is fairly large, whereas that toward the violet side is very small The glass is extremely transparent to Rontgen rays, which it lets through, roughly, ten times as well as ordinary glass The specific gravity is 2 2, the hardness, 6. The glass can be cut and polished without difficulty. The cubical expansion coefficient (calculated from the constants of Winkelmann and Schott) is $118\ 10^{-7}$, about half that of ordinary glass It has been found that, as a general rule, the transparency for rays of short wave-length increases in analogous salts as the atomic weight of the metal decreases, but sufficient experimental data have not yet been obtained to warrant the publication of a definite formula

A NEW high-tension condenser on the Moscicki principle is likely to prove a useful commercial apparatus if, after testing in practical work, it fulfils the advantages claimed for it in a very complete and interesting pamphlet which we have received from Messrs Isenthal and Co, who are agents for the makers A condenser made on this principle is now on view in London, and the construction is very neat and convenient, any number of condenser elements being grouped together in a battery very easily according to the voltage required The chief advantages claimed over other condensers are the (1) strengthening of the dielectric to minimise the chances of rupture, (2) perfect contact between dielectric and armature plates, (3) prevention of local heating by means of a cooling chamber, (4) no organic substances used These condensers have been used successfully for the protection of live wires against atmospheric discharges, wireless telegraphy, suppression of lag in alternating currents and in X-ray work, and the construction of the condenser certainly renders it much less liable to breakdowns, which in practical work prove very serious The opening in wireless telegraphy work alone for a condenser which can be depended upon is very great, and the new condenser will no doubt be given a thorough trial in many ways as a practical commercial condenser has long been demanded

A SECOND communication on anode rays is published by Messrs Gehrcke and Reichenheim in No 4 of the *Verhandlungen* of the German Physical Society (compare NATURE, this vol p 173) An arrangement of apparatus is described by means of which the phenomena produced are made very striking by using high potentials obtained with anodes permitting of more continuous working in a high vacuum A brilliant fluorescence is observed on permitting the "rays" from the anode to impinge on a mica screen or on the glass walls of the vacuum tube The colour of the fluorescence is the same as that of the emission spectrum of the metal present in the salt used at the anode, thus with lithium carbonate the light is reddish in colour, and in the spectroscope shows the red and orange lines of lithium The admixture of another substance, such as graphite or zinc dust, with the salt used as anode facilitates the formation and improves the character of the rays It is noteworthy that the anode rays cannot be produced from a cold anode, and that usually some interval elapses, during which heating occurs, after the current has been switched on before they make their appearance The volatilisation of the salt may therefore play an important part in their production

SINCE "synthetic" indigo was put upon the market in 1897, some uncertainty has existed regarding its tinctorial value as compared with the natural dyestuff The makers of synthetic indigo have maintained that the only significant constituent of natural indigo is indigotin, identical with the synthetic substance, and that the other components present in the natural dye are either inert or harmful impurities On the other hand, certain practical

dyers have held that the natural dye gives a certain richness of shade, or "bloom," which is invariably absent from goods dyed with synthetic indigo. The results of a practical dye test of the two materials, made with the object of throwing light on this disputed question, are described by Mr. Cyril Bergtheil in a report to the Bihar Planters' Association. The conditions were such as to be strictly comparable for the two materials as regards concentration of dye bath, temperature, and fabric dyed. The results obtained, working on the large scale under practical conditions and with dye baths of the same strength, were such as to uphold the objection of the dyers already referred to against the synthetic dye. Natural indigo not only gave a richer shade with the characteristic "bloom," but also actually a darker shade. The difference between the natural and synthetic material, which is hardly apparent in dyeing trials made on the small scale, appears to become of considerable importance under conditions such as exist in actual practice.

The third fasciculus of the first volume of Prof. O. D. Chwolson's "Traité de Physique," which is being translated from the Russian and German editions into French by M. E. Davaux and supplied with notes on theoretical physics by MM. E. and F. Cosserat, has been received from M. A. Hermann, of Paris, who is publishing the work. Two previous parts of this excellent treatise were reviewed at length in our issue for February 15, 1906 (vol. lxxiii., p. 362), and it is unnecessary on this occasion to say more than that the present part deals with the liquid and solid states of bodies, and maintains the same high standard which characterised the previous issues.

The Chemical Publishing Co., of Easton, Pa., has just published "Inorganic Chemistry for Schools and Colleges," by Mr. J. L. Howe. The book is an enlarged and revised edition of "Inorganic Chemistry according to the Periodic Law," by Prof. F. P. Venable and Mr. Howe. The number of experiments has been increased, and prominence has been given to the applications of chemistry. The book is published in this country by Messrs. Williams and Norgate.

In the new issue of section i. of the catalogue of Mr. Charles Baker, of High Holborn, London, microscopists will find detailed information of a great variety of microscopes and accessory apparatus.

A sixth edition of "The Essentials of Chemical Physiology" by Prof. W. D. Halliburton, F.R.S., has been published by Messrs. Longmans, Green and Co. The book has been subjected to a thorough revision, and many parts have been re-written in order to incorporate recent advances in the knowledge of the proteins and of the way they are utilised in the body, together with the results of other researches.

The authorised English translation of Dr. Ludwig Jost's "Lectures on Plant Physiology," done by Prof. R. J. Harvey Gibson, of Liverpool, will be issued very shortly by the Clarendon Press. The Press also announces the second volume of Dr. Paul Knuth's "Handbook of Flower Pollination," translated by Prof. J. R. Ainsworth Davis, of Aberystwyth, containing an account of all known observations upon the pollination of the flowers of plants of arctic and temperate zones.

A third edition of the late Mr. Herbert E. Wright's "Handy Book for Brewers" has been published by Messrs. Crosby Lockwood and Son. The first edition, which appeared in 1892, was reviewed in Nature for November 24, 1892 (vol. xlvii., p. 75). In the present issue, not only has the size of the volume been increased by more than fifty pages, but very many paragraphs have been re-cast and fresh matter inserted. The work of Buchner and others on zymase has been dealt with, and a synoptic table of enzymes has been included.

A new edition of "The Imperial Gazetteer of India" is announced by the Oxford University Press. This may be considered as a new work rather than a new edition, and it will consist of twenty-six volumes, including a companion atlas. Apart from the historical volume and a few other chapters of the Indian Empire, the whole of this work has been written by officials in India under orders of the Indian Government, and every page has been submitted to the criticism of the several administrations or departments concerned.

OUR ASTRONOMICAL COLUMN

Comet 1907*b* (Mellish).—The following elements and ephemeris for comet 1907*b* have been computed by Messrs. Lamson and Frederick from places observed on April 15, 16, and 17:—

Elements.

$$T = 1907 \text{ March } 27.56 \text{ (G.M.T.)}$$

$$\left.\begin{aligned} \omega &= 328^\circ\ 47' \\ \Omega &= 189^\circ\ 7' \\ i &= 110^\circ\ 12' \end{aligned}\right\} 1907{\cdot}0$$

$$\log q = 0.924$$

Ephemeris 12h. Greenwich M.T.

1907	α (h. m.)	δ
April 22	7 46	+35 36
,, 26	8 4	+40 58
,, 30	8 17	+44 17

The brightness is decreasing rapidly from 0.59 on April 18 to 0.11 on April 30, the unit of brightness being that when the comet was first discovered (mag. 11·0). The comet is now circumpolar, and is travelling through the constellation of the Lynx in a north-easterly direction, towards Ursa Major (*Kiel Circular*, No. 96).

A New Variable or Nova 156.1906.—In the *Atti della Reale Accademia dei Lincei*, vol. xvi. (fifth series), p. 241 (March 3), Prof. E. Millosevich records the observations of a faint star which is certainly an interesting variable, and may prove to be a fading Nova. On November 6, 1906, the star in question was first noticed as a yellow object of magnitude 8.4, its position being

$$1906.0\ \alpha = 1\text{h. } 23\text{m. } 56.50\text{s.},\ \delta = +50^\circ\ 22'\ 12''.1$$

Subsequent observations showed that the star was fading, the decrease in brightness being roughly proportional to the time, and amounting to about 0.3 magnitude in ten days. By February 26, 1907, the magnitude had decreased to 12.3, the colour, in the interval, having passed through successive stages from yellow to red to quite a ruby-red, which was still notable on February 19, when the magnitude was but 12.0.

The Albedoes of the Superior Planets.—A novel method of calculating the albedoes of the superior planets is suggested by Mr. J. E. Gore in No. 382 of the *Observatory* (p. 172, April). The mass of the brighter component of α Centauri is equal to that of the sun, and their spectra are similar, thus the star may be considered as a duplicate of the sun, and Mr. Gore proposes to estimate the albedoes of the superior planets by comparing their photometric magnitudes when in opposition with that of α Centauri.

In a previous paper Mr. Gore has shown that, taking the parallax of the star to be 0″.75, and assuming the diameter of its brighter component to be the same as that of the sun, the apparent brightness of our central luminary is 75,232,650,000 times that of the brighter component of α Centauri.

Connecting this with the amount of sunlight inter-

cepted by the planet, the planet's mean distance and its photometric magnitude at opposition Mr Gore evolved a formula which gave the following values for the albedoes of the several planets:—Mars, 0·2072; Jupiter, 0·595; Saturn, 0·6744; Uranus, 0·61; and Neptune, 0·6276.

The Second Globular Cluster in Hercules, Messier 92.—No. 3, vol. viii., of the *Astronomiska Iakttagelser och Undersökningar å Stockholms Observatorium* is devoted to a discussion, by Dr. Karl Bohlin, of the measures of a plate showing the cluster Messier 92, taken at Stockholm on April 29, 1898. The conditions of measurement and the corrections applied are discussed in full, the actual measures being tabulated. The number of stars considered is three hundred and forty-eight, and of each of these the position and magnitude for 1898·0 are given. In a third table the resulting places are compared for twenty-nine stars, with those obtained from measures made at Upsala in 1873, and the apparent proper motions deduced. A diagram given at the end of the volume shows these proper motions graphically, the greatest differences (Stockholm-Upsala) being $\Delta\alpha=+6''.6$ and $\Delta\delta=-4''.6$, whilst the mean values are $+1''.5$ and $-1''.7$ respectively.

Halley's Comet.—*Knowledge and Scientific News* for March (No. 3, vol. iv., p. 57) contains an interesting article by Mr. F. W. Henkel on Halley's comet. Mr. Henkel discusses cometary phenomena and mechanics in general, showing their application in the observed appearances of Halley's famous object in particular. The apparitions are carried back as far as 1066, although the identity of the object represented on the Bayeux tapestry with that known as Halley's comet cannot yet be regarded as beyond doubt; probably the investigation now being carried out by Mr. Crommelin may settle this question. Many other interesting points, such as the perturbative action of Jupiter, the existence of an interplanetary resisting medium, and the various features presented by Halley's comet at previous apparitions, are dealt with in a very simple manner in Mr. Henkel's paper.

Eclipses of Jupiter's Satellites, 1878–1903.—The results of the photometric observations of the eclipses of Jupiter's satellites carried out at the Harvard College Observatory between June 23, 1878, and the end of 1903, are published by Prof. E. C. Pickering in part i., vol. lii., of the Annals of the Astronomical Observatory of Harvard College. The present publication contains simply the observational records in detail, with notes on the same, and a catalogue of the eclipses which were observed. The discussion of the entire material by Prof. R. A. Sampson, of Durham University, will appear in part ii. of the same volume.

RAINFALL IN GERMAN SOUTH-WEST AFRICA.[1]

In spite of native risings and recalcitrant Parliaments, our German cousins manage to carry on meteorological observations in their African possessions, and some results of their work which are of great importance in connection with the general meteorology of South Africa have just been issued as a supplement to the official "Deutsches Kolonialblatt." In the first section of this publication Dr. Ottweiler has collected and re-printed all trustworthy rainfall records—both official and unofficial—from German South West Africa, and, for the sake of completeness and comparison, he has added returns from a number of stations in the adjoining British and Portuguese territories. For this alone, meteorologists will be grateful to him. A supplementary table giving the positions and heights of the stations, and in most cases a brief description of the orographical features of the country surrounding them, will also be welcome.

As is to be expected in so "young" a country, the material collected is far from homogeneous, and, moreover, most of the stations are of very recent date. The author thus had before him the task of "weighting" the means deduced from the observations to render them approximately comparable among themselves before proceeding to discuss results. The process is not entirely satisfactory, but unless we are to refrain from drawing conclusions until a homogeneous body of statistics is available, some manipulation of the figures is necessary.

The results, which are illustrated in a number of admirable plates, are of exceptional interest, though they will be disappointing to those concerned with the economic development of the country. The coastal districts may be described as practically rainless, which is remarkable, as the prevailing winds are southerly or south-westerly throughout the year, and the land rises tolerably rapidly. In most parts of the world, sea breezes blowing on to rising land yield a copious rainfall, but on the coast of German South-west Africa the air is derived from higher and colder latitudes, and, as it blows over the cold Benguela current before it reaches the land, it contains little moisture when it commences its forced ascent. The heating effect of the sun far outweighs the dynamical cooling due to the ascent, and the condensation stage is never reached. Practically the only moisture which reaches the land near the coast is derived from the heavy fogs, which in winter are of almost daily occurrence. The winter rainfall, which is so prominent a feature in the west of Cape Colony, does not extend north of the Orange River.

In the more eastern inland districts the dry south-west wind prevails throughout the winter, and this portion of the year is accordingly rainless. In summer the wind shifts to the eastward, and a limited amount of moisture manages to reach the country from the Indian Ocean. In the neighbourhood of Windhuk the average annual rainfall is about 12 inches or 14 inches, and in the extreme north-east of the colony it exceeds 26 inches.

When the details of this fall are examined its value for economic purposes is found to be but small. Great fluctuations occur in the annual totals, which are of all the more importance, as the amounts are so small. Thus in the country round Windhuk the fall during the last twenty years has fluctuated between 47 per cent. and 210 per cent. of the average. Further to the south, conditions are considerably more unfavourable.

Great variability in the annual rainfall is not the only disadvantage from which the country suffers. Almost all the rain falls in thunderstorms, and torrential downpours are the rule rather than the exception. A single, though by no means isolated, instance will suffice to give an idea of the prevailing conditions. At Udabis in the year 1900 the total rainfall was 9·5 inches, and of this amount 6·5 inches fell in the course of three consecutive days, leaving only 3 inches to be distributed over the remaining 360 odd days.

It is interesting to compare the German results with those which have just been issued by the Governments of British East Africa and Uganda for the year 1905. In British East Africa the annual totals at thirty-three stations ranged from 16 inches to 99 inches. Only four stations experienced more than two absolutely rainless months, and in only two cases were these consecutive. A summary of totals for past years, which is appended to the report, shows considerable fluctuations in the amount. At three stations with records extending over at least eight years the totals fluctuate from about 40 per cent. to about 150 per cent. of the mean value for this period.

From Uganda rainfall data are given for nine stations. The totals for these varied from 37 inches to 96 inches. Only one station had an absolutely dry month. At Entebbe the year was the wettest on record. The total fall was 65·74 inches, 112 per cent. of the average for the last six years. Ten years' records (the first four incomplete) now exist for this station. During this period no absolutely dry months were experienced.

The British Empire has not yet produced a work on the meteorology of any of its possessions in tropical Africa which can be compared with that just issued in Germany, but it is gratifying to find that the Governments responsible for the administration of our share of the Dark Continent are realising the importance of meteorological observations, and of their systematic publication.

[1] Wissenschaftliche Beihefte zum deutschen Kolonialblatte, 20 Band, 1 Heft. Mitteilungen aus den deutschen Schutzgebieten. Die Niederschlagsverhältnisse von Deutsch Südwestafrika. By Dr. F. von Danckelman. Pp. 84. (Berlin: S. Mittler und Sohn, 1907.)

THE RIVER PILCOMAYO[1]

THE river Pilcomayo has its source in the Bolivian mountain ranges, and traverses the virgin forests of the Gran Chaco in a south-easterly direction. For nearly two hundred years the idea of utilising this river for purposes of navigation has engaged the attention of the Governments of Argentina, Bolivia, and Paraguay, in order to provide the rich regions through which it passes with an easy means of communication, and to afford an outlet by water for the natural products of the fertile zones of the eastern part of Bolivia.

The author of the report before us, who is a member of the American Society of Engineers, was appointed by a syndicate of capitalists in 1905 to conduct an expedition for the purpose of studying the navigable condition of the river, and reporting as to the possibility of rendering it fit for the passage of boats.

The exploration party consisted, besides the chief, of two assistants, a land and forest expert, storekeeper, and twenty-five men. They took with them for the purposes of transport twenty-two mules, forty-one horses, sixteen oxen and five boats. Twenty-two bullocks were also taken for food. The expedition occupied four months.

The country traversed appears to be sparsely inhabited by Indians who on the whole are friendly. A colony has been established at Buena Ventura, about 560 miles up the river, which contains thirty families of colonists, with a total population, including servants, "intruders," and squatters of 1000 souls. There are also in the district some Roman Catholic mission stations.

The river Pilcomayo discharges into the Paraguay, the depth at low water at its junctions being about 10 feet, and above this for sixty miles there are no soundings less than 10½ feet. At 120 miles the depth decreases to about 7 feet; at 150 miles there was barely 3 feet. At about 317 miles from its mouth the river is lost for ten miles in a marshy tract of country, through which there does not exist any defined channel. Beyond this tract, which constitutes an immense horizontal plane extending to "distances unknown" at 327 miles from the mouth the river again assumes a defined channel with a depth of from 10 feet to 12 feet. This channel was explored up to the Argentine boundary at El Hito 677 miles from the mouth. The width varies from 100 feet at the lower end where the course is well defined, to 300 feet in the upper part.

In the lower part of the river the water is brackish and unfit to drink, owing to a number of salt springs, and in the upper river it is turbid and of a reddish colour.

To render this river navigable for barges carrying twenty-five tons and drawing 4½ feet of water, over a length of 670 miles, or about 100 miles beyond the colony of Buena Ventura, the commission advised the construction of three cuts or canals, one to avoid the marshy district and the two others two porous districts in the upper length; these cuts to have a bottom width of 33 feet with 5 feet depth of water, the construction of seventy-three locks and dams, the regulation of the channel and clearance of obstructions. The amount required to carry out these works is estimated at a sum equal to about one million of English money.

CRETACEOUS FERNS[2]

THE author states that he approached the subject of palæobotany as a layman whose earlier training had been mainly in physics and mathematics. He set himself to collect such fragmentary remains of fossil plants as the Lower Cretaceous rocks of his neighbourhood afforded, with the intention of making an intensive study of the several genera. This first instalment of his results deals mainly with a single genus of Mesozoic ferns, to which Dunker in 1846 gave the name Hausmannia. The fronds of this genus are characterised, in some species, by the possession of a bi-lobed lamina not unlike that of the leaves of the maiden hair tree (*Ginkgo biloba*), while in other forms the lamina is divided into several linear lobes, and bears a resemblance to the leaves of Baiera, an extinct genus of the Ginkgoales. It is, however, with the recent Indian and Malayan fern Dipteris that Hausmannia exhibits a more than superficial resemblance. Despite the unfavourable nature of the Quedlinburg rocks from the point of view of preservation of detail, Prof. Richter's industry has been rewarded by an accumulation of material which has enabled him to add considerably to our knowledge of this well-defined genus of ferns. He has instituted, on what appear to be adequate grounds, a few new species. The flora of Quedlinburg is characterised by a preponderance of ferns, which are said to form 80 per cent. of the whole; no trace of Angiosperms has been found; Conifers and Cycads are rare, while ferns are represented by the Gleicheniaceæ, Matonidium, Laccopteris, Clathropteris, Hausmannia, Weichselia, and a few fragments of the common Wealden species *Onychiopsis Mantelli*. It would seem that in these fossils we have the relics of a vegetation which flourished in a situation favourable to ferns. Ferns undoubtedly played a more prominent part in the composition of Mesozoic floras than in the floras of the present, but it is unlikely that the Quedlinburg flora as a whole was composed almost entirely of these plants to the exclusion of Lower Cretaceous Gymnosperms which are recorded from other localities.

Prof. Richter's contribution does not throw any fresh light on the nature of the sporangia of Hausmannia; he has, however, demonstrated a striking resemblance in habit to recent species of Dipteris as regards the slender rhizomes and long leaf stalks. The author is disposed to regard the affinity between this northern Lower Cretaceous type and the Malayan Dipteris as rather less close than has been assumed by Prof. Zeiller and by the reviewer. In the absence of well-preserved sporangia the question of degree of relationship cannot be settled, but the account given of such fragments of fossil ferns as were accessible to the author of this monograph seems to strengthen the view that the Dipteridinæ were abundantly represented in the northern hemisphere in the latter half of the Mesozoic era. In age the flora is considered to be rather younger than Wealden, and is compared with the Urgonian flora of Greenland as described by Heer. It is difficult to draw a conclusion as to geological age from the small number of types so far described, but in our opinion the Quedlinburg plants might fairly be classed with the Wealden floras of northern Germany, England, Belgium and many other regions.

Prof. Richter has done good service to palæobotany by his thorough and scientific researches, and one may express a hope that other amateurs may follow his example and devote themselves with equal energy and success to the detailed study of the fossils of a single district.

A. C. S.

PROBLEMS OF APPLIED CHEMISTRY[1]

THE science and art of the engineer are intimately interlaced with those of the practical chemist. The practical, as distinguished from the scientific, chemist possesses sufficient knowledge and experience to see to the working of machines and to minor repairs without calling in an engineer, save in difficult or complicated cases. In former times the chemical manufacturer learned his trade both on the chemical and the engineering side, as far as it was indispensable, but he learned it simply "by rote," as the saying goes. To be sure, this never took place without large sums of money being thrown away, either in the form of misshapen or faulty apparatus and machinery, or of spoilt chemicals, and so on. And this happened to the unstudied "practical man" who through family connections or by mere chance, had stumbled into chemical manufacturing, as well as to men who had studied the science of chemistry and who desired to apply the knowledge thus gained to the execution of some well-known process or to the working of some laboratory in-

1 "The River Pilcomayo from its Discharge to Parallel 22 S., with Maps of Reference." By Gunnar Lange. Pp. 124. Translated from the Argentine Original. (Buenos Aires: The Meteorological Office Press, 1906.)

2 "Beiträge zur Flora der unteren Kreide Quedlinburgs. Teil I., Die Gattung Hausmannia, Dunker, und einige seltenere Pflanzenreste." By Prof. P. B. Richter. Pp. iv+27+plates. (Leipzig: W. Engelmann, 1906.)

1 Abridged from a discourse delivered at the Royal Institution on Friday, March 15, by Prof. George Lunge, of Zurich.

vention on a large scale Those men who possessed a scientific foundation were, in their turn, compelled to learn the technical side of their profession by dint of practice, just as the tailor has to learn the art of making clothes and the barber the art of shaving A man of scientific attainments had certainly, even in the olden times, a clear advantage over the mere "practical man"

But many branches of manufacturing, which undoubtedly have a chemical basis, and in which to-day a large number of chemists are actually employed, were formerly carried on in a purely empirical manner like any handicraft, for instance, soap-making, tanning, brewing—indeed, all those industries which are connected with food—and above all, dyeing and tissue-printing But towards the middle of the last century we perceive the commencement of a scientific treatment of those industries Even before then, the genius of Chevreul had thrown a flood of light on the chemical behaviour of fatty substances and Persoz followed in the domain of dyeing fabrics The cooperation of the various arts and sciences was distinctly promoted by the technical high schools in France, Germany, and Switzerland

In Great Britain the chemical industries had from the first taken their full share in the astounding development of all branches of industry which in this country has for several centuries enjoyed an uninterrupted peace, whilst continental Europe was lacerated by frequent wars Thus Great Britain had a long lead in all the fields of commerce and industry

Some of the most important of the chemical industries have, indeed, altogether *originated* in this country, especially that of sulphuric acid and that of chloride of lime, both of which date back as far as the eighteenth century, But it is only fair to remember that some of the most important improvements in these manufactures are due to French inventors and French men of science To France we owe the invention of the Leblanc process, which could not be at once introduced into this country, owing to the fact that common salt was burdened with an absolutely prohibitive excise duty The abolition of this tax in 1823 acted like the wave of a magic wand, not merely in calling into life the manufacture of alkali itself, but by giving a strong impetus to all the chemical industries connected therewith, viz those of sulphuric, hydrochloric, and nitric acid Almost immediately the tide of inventions and improvements set in, and a few decades later we find Great Britain absolutely dominant, not merely in the branches just mentioned, but generally in the field of inorganic chemical industries For many years up to 1870 about, this predominance was not seriously called into question

In this manner inorganic chemical industry was developed in Great Britain up to the middle of last century to a greater extent than in any other country, by men like the Muspratts, Tennant, Gossage Dunlop, Chance, and many others Most of them were neither studied chemists nor engineers, but in their school any theoretically educated chemist could immensely profit for the work of factory-manager

In close connection with this state of matters we find in England among the greatest inventors men who, at the outset, did not even possess a routine knowledge of the field in which they achieved their later successes, and who were altogether "outside the profession," like Walter Weldon Henry Bessemer, Sydney Gilchrist Thomas

Peculiar to England is also the case of William Henry Perkin who, at the early age of sixteen, entered Hofmann's laboratory in London Two years afterwards he discovered the colouring matter called "mauve," the forerunner of all colours produced from coal-tar, and only a year later he built a factory for producing his mauve, which at once proved a success and laid the foundation for his splendid work in after life

One of the great problems presented to applied chemistry in the last century, at which many inventors in all industrial countries have been working, was the utilisation of "alkali-waste" The first partial success in this direction was scored in 1861 by Ludwig Mond and by Max Schaffner. One of the first patents referring to it was taken out in 1837 by Gossage He quite rightly recognised a number of the conditions necessary for realising that reaction, but, unfortunately, not all of them It soon became manifest that there were unforeseen difficulties not yet overcome The missing links in the process were only discovered in 1883 and 1887, and led to the application of that process at all the Leblanc works This final success is connected with the names of Carl Friedrich Claus and of Alexander Chance

Many German chemists (as well as the speaker himself) at that time came to England for their practical education, for instance, Caro, Pauli, Martius, Peter Griess, and Ludwig Mond The two last-named have permanently associated themselves with this country, whilst the three first-named, as well as many other German chemists who had found a temporary home in England, returned later on to their own country, and these very men have been in the forefront of those to whom is due the remarkable development of German chemical industry.

Formerly the German professor, as well as his students, had been frequently held up to ridicule, not merely abroad, but at home as well, as idealistic dreamers, unsuited to the wants of real life and to the requirements of trade and manufacture, and in this there was only too much truth, so long as they were not in intimate touch with men of practice But at last an amalgamation between these two classes of men took place Within a very few years there arose those enormous establishments at Ludwigshafen, Hochst, Elberfeld, Berlin, Darmstadt, and elsewhere, which are conducted on a scientific basis, but with the most extensive utilisation of all the attainments of manufacturing experience Austria, France, Switzerland, Belgium, and America have all made immense strides in that direction. And what of Great Britain? Seeing that in pure science the people of Great Britain have never lagged behind *any* other nation, and that, on the contrary, the land of Newton and Faraday has been a beacon to all others at more than one epoch, there is absolutely no valid reason why she should now, or at any other time, be behind any other in the combination of science with practice

The history of the ammonia-soda process has been directly contrary to so many others It was invented by two Englishmen, Dyar and Hemming, in 1838, who did not succeed in the *practical* application of their invention, nor did their numerous successors meet with any better fortune A Belgian engineer, Ernest Solvay, found the first economical solution of that problem, and the economical superiority of the ammonia over the Leblanc process soon became evident This was brought home to English manufacturers by the success of the firm of Brunner, Mond and Co The Leblanc process, and the enormous sums of money invested in it, seemed even then doomed to speedy extinction But for a time, at least, this calamity was averted by the perseverance with which the British alkali makers kept making improvements in the Leblanc process The prolongation of its life is due to the fact that in the first stage of the process an important acid is produced, which is not furnished by the ammonia process, viz hydrochloric acid Most of this is immediately converted into chlorine, which gas is used up for preparing bleaching powder, bleach liquors, and chlorates Of these, bleaching powder is a British invention made by the Glasgow chemist, Tennant, but, apart from this, the manufacture of chlorine and of all chlorine products has been put on its practical basis almost entirely by English inventors, and has been developed more extensively in this country than anywhere else in the world But this last entrenchment of the Leblanc process is being vigorously assaulted from another quarter—by the electrolytic processes, which split up the alkaline chlorides directly, and in the simplest possible manner, into free chlorine and caustic alkali

Even now it is only quite exceptional that, wherever the electrical current has to be produced by means of *steam*, electrochemical methods can compete with the older ones for the manufacture of what is called "heavy chemicals" Just those two European countries which are the greatest producers of coal, Great Britain and Germany, are less favoured by nature in respect of water-power than other countries which possess little or no stores of mineral fuel, as Sweden, Norway, Switzerland, France, Italy, and Spain A very different condition of affairs

obtains in the United States, where we find the greatest coalfields combined with the greatest amount of water-power existing in any civilised country. The day will inevitably come when the coalfields will be so far exhausted that all those industries which consume large amounts of mechanical energy will be forced to emigrate to countries where water-power is abundant.

No other substitute has, as yet, been found for generating force, and, indirectly, electricity.

Even in those countries which are more favoured, the amount of water-power is by no means infinite, and, if it had to be drawn upon, not merely for motive purposes, but for the production of electricity for heating purposes, it would be found insufficient in most places. Here we are faced by one of the greatest problems of applied science, both in chemistry and in physics, a problem which will give plenty of occupation to generations of future inventors. At present we can only surmise that some solution will present itself in the shape of a direct conversion of the sun's rays into other forms of energy, but the means by which this would be *practically accomplished* are at present quite uncertain.

Seeing that the stock of mineral fuel upon this earth is so very limited, cannot we find means of husbanding it more than this has been done hitherto? Of the energy residing in coal most ordinary steam-engines utilise less than 10 per cent., and even the most perfect steam-engines hardly more than 15 per cent. The conversion of pig iron into steel, the manufacture of glass, and many other industries consume from four to twenty times and even more the quantity of coal required by theory. Moreover in burning our fuel whether it be for industrial or for technical purposes we invariably send its nitrogen into the atmosphere, which surely contains quite enough of that commodity, the only exception being the manufacture of coal-gas. Here some of the grandest problems of applied chemistry present themselves to us—how to stop that fearful waste of fuel and how to recover the nitrogen of the coal, if that be possible.

It is certain that we must look for the solution of these questions in the direction of converting coal into gaseous fuel. Another great stride ahead lies in the better utilisation of the waste gases from blast furnaces, in which respect the last few years have witnessed some very important improvements. All this refers merely to a better utilisation of the heating power of coal, but not to that other great task, the recovery of its nitrogen in a useful shape.

The immense importance of the problem lies in the fact that it touches our most urgent want, our supply of food. For agricultural purposes it does not make much difference whether we apply the nitrogen in the form of ammonia or of nitrates. The ammonia, apart from insignificant quantities otherwise obtained, all comes from the nitrogen of the coal, but up to about twenty years ago only that coal which was used in the manufacture of gas was made to yield ammonia, and only one-sixth of its nitrogen was obtained in this form. In the manufacture of coke, which is also a process of destructive distillation and entirely analogous to gas making, very much larger quantities of coal are consumed. Up to about twenty years ago all the volatile by-products in the manufacture of coke were lost—that is to say, tar, gas, and ammonia. Even now both in France and England, as well as in America, the recovery coke-ovens have found only a very limited adoption. In England perhaps 5 per cent. of the coke is made in this way against upwards of 50 per cent. in Germany.

But that reserve is, after all, nothing like sufficient to cover the requirements of agriculture in the future, and it is quite likely that in the long run all the really available nitrogen of the coal would not suffice for the wants of man. And what about the time when coal itself will be exhausted? Well, there is an eternal and inexhaustible source of nitrogen in the atmospheric air. Four-fifths of *this consists of nitrogen, calculated to amount to* 4000 billions of tons. But until a very few years ago the problem of turning the atmospheric nitrogen into ammonia or nitric acid, although frequently approached in a purely scientific or, experimentally, in a technical way, had not been solved. Our days have seen the realisation of that most important task.

Let us first speak of ammonia. We must start from calcium carbide. Prof. Adolf Frank and Dr. Caro, of Berlin, found that when nitrogen is passed over red-hot calcium carbide it is absorbed with formation of calcium cyanamide. This latter, when treated with water under high pressure, is made to yield ammonia; but it is not necessary to do this, since the crude product, which they have called "lime-nitrogen," can serve directly as nitrogenous fertiliser, and is in that respect equivalent to its own weight of ammonium sulphate. The works already in operation, or in course of construction, will by the end of this year utilise water-power to the extent of some 55,000 horse-power, and will produce lime-nitrogen equivalent to 100,000 tons of nitrate of soda.

Important as ammonia is as a fertiliser it ranks after the nitrates in that respect, and, unlike ammonia, the nitrogen of the nitrates is of immense importance for other purposes as well, viz. the manufacture of nitric acid and of explosives. These have, up to the present, been prepared almost exclusively from Chilian saltpetre. What, then, shall we do when the *nitre beds of Chili are exhausted?* an event which, according to most estimates, is bound to take place within thirty or forty years from now. Unfortunately, there is no tangible hope of similar beds being found in any other localities, certainly not to any great extent. The solution of *this* problem, if not altogether settled in its final shape, has now been found by means of that well-nigh omnipotent agent, electricity. At Notodden in the Norwegian Hitterdal a factory has been established to carry out the process of Birkeland and Eyde, who, by an ingenious application of the extreme heat produced by the electric current, make the nitrogen and oxygen of air combine to form nitric oxide, which at a lower temperature is spontaneously oxidised into nitrous vapours, with the ultimate production of nitrites or nitrates. This time there is really no doubt that a practicable and economical process has been discovered, for which it is intended to employ by the end of this year water-power to the extent of 30,000 horse-power. The Notodden process bids fair to be followed by other even more efficient processes. The most important of these is that of the Badische Anilin und Soda-Fabrik, for which an experimental factory is in course of construction, and for which 50,000 horse-power are to be employed.

Electricity has often been invoked to produce the most important of all inorganic products, iron. If this problem could ever be solved in an economical way it would bring about a perfect revolution in the position of the leading nations. On the one hand, the enormous quantity of coal now consumed in the production of iron and steel (which is probably at least a quarter of the entire output of coal) would be set free for other uses, and the exhaustion of the coal-fields would be put off to a corresponding extent. On the other hand, the production of iron would pass over into the hands of those nations which command the largest amount of water-power, and which, therefore, can *produce electricity most cheaply*. Of the three countries which now produce between them the bulk, that is, seven-eighths, of the world's iron, Great Britain and Germany would go to the wall, and the United States, which already produce more iron than these two countries put together, would become omnipotent in that field.

One of the problems belonging to the domain of organic chemistry is the substitution of artificial for natural colouring matters. This, indeed, has now been carried out almost to the bitter end. Long ago, one of the oldest and most widely used colouring matters, that contained in madder, succumbed to the attacks of the chemists, among whom the names of Edward Schunck and William Henry Perkin testify to the glorious share taken by Englishmen in that victory. The colouring substance of madder—alizarin—is now made from English coal-tar, and has altogether taken the place of the impure form in which it occurs in the madder plant. The growers of this plant in the south of France and elsewhere have had to abandon its culture altogether, to their great sorrow.

A similar fate has already partly overtaken, and may, in the end, destroy entirely the culture of indigo. Synthetic indigotin is now manufactured at such a low price that its competition has proved a severe blow to the indigo-planting interests. Thus the triumph of scientific investi-

gation and practical skill in chemical manufacturing, gratifying though it be as a splendid achievement of applied chemistry, is a sad trial to many thousands of Indian ryots and their British masters, and this is merely the foretaste of what will inevitably happen in many other cases. What is food for one is poison for another.

Perhaps the very greatest problem of applied chemistry is the direct production of feeding-stuffs for man and beast. The synthesis of alimentary substances from inorganic matter has up to this moment, not been even remotely achieved, nor can we at present so much as guess the direction in which this might be done whilst, as for the production of food from sawdust and other waste organic substances we are in no better case. But even here the word "impossible" should not be pronounced. In a more modest form at all events chemistry has found magnificent scope in that quarter, viz. in the extraction of alimentary substances from new sources and in the increase of production from old ones. The colossal industry of beet root sugar is an instance of the former whilst agricultural chemistry, as a whole works in the latter direction.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

COURSES of lectures, and arrangements for informal instruction have been arranged by the Oxford University Committee for Anthropology for the coming Easter term. There will be lectures and other instruction in general anthropology, physical anthropology psychology, geographical distribution, prehistoric archæology, technology, sociology (religion, law custom &c), philology, and other subjects of interest to students of anthropology.

THE sum of 6100*l* has been subscribed by alumni of Harvard University to establish a Shaler memorial fund in commemoration of the long services of Prof. N. S. Shaler and of the great affection in which he was held by his many students and friends. It is proposed to place a memorial tablet in the geological section of the University museum or some other suitable place, and to use the income of the balance for the benefit of the division of geology in support of original research and in the publication of the results of research.

ON Tuesday April 23, the Prince and Princess of Wales visited Glasgow and opened the new buildings at the University. These buildings were erected by Principal Story's university fund, which was largely raised by the efforts of the late Principal. They form an important addition to the laboratory and lecture room equipment of the University. They consist of two large detached institutes to the west of the main building, one provides accommodation for the departments of physiology materia medica, forensic medicine, and the other for the department of natural philosophy. The cost of the buildings has been defrayed by subscriptions to the amount of 80,000*l* from the citizens of Glasgow and a grant of 40,000*l* from the Carnegie trustees. A special honorary graduation was held on the same day, at which the honorary degree of LL.D. was conferred on the Prince and Princess of Wales, the Lord Provost of Glasgow (Mr. Wm. Bilsland), the Duchess of Montrose, the Chancellor of the Exchequer, who is also Rector of the University, Right Hon. Geo. Wyndham a former Rector, Mr. Ure the Solicitor-General for Scotland, Sir George Watt, Sir W. R. Copland, Miss Galloway, Prof. Emile Boutroux, Prof. Norman Collie, Prof. J. H. Poincaré, Mr. Sidney Lee, Mr. D. S. MacColl, Mr. Jas. A. Reid, Mr. N. Dunlop, Prof. J. G. McKendrick, Prof. G. G. Ramsay, Prof. A. M. Stuart, and Principal Donald Macalister.

ON Saturday last, April 20, the Borough Polytechnic Institute was open for the annual inspection and display of students' work. To judge from the crowds which thronged through the building during the evening, those who live in the neighbourhood must take a great interest in this educational centre. In the chemical laboratory there was an exhibition of electrochemical apparatus and one saw the rapid deposition of metals by means of rotating electrodes. Apparatus for measuring the absorption taking place in reduction and oxidation methods was also shown working. In the general laboratory various chemical operations were in progress, such as fractionation, steam distillation, and the like. The general public who crowded the laboratories did not, of course, understand much, but they realised that what was to them mystical chemistry might be interesting, and perhaps a few of them will become students. The recently equipped electrotechnical department, which is in the engine-room, caused a good deal of interest. Many of the fittings have been put up by the students, who also helped to build up the experimental dynamo. The engineering department is becoming very complete, and students can now carry out tests upon quite a large scale. The latest addition here is a De Laval 5 horse-power steam-turbine engine coupled on to a dynamo. Some of the metal work and wood work executed by the students was of a very creditable character, the hammered copper work being especially interesting. A noteworthy exhibit was a vernier with micrometer screw which had been entirely made—scale and all—by a lad sixteen years of age in the technical day school. The average person who passed through the institute on Saturday night would probably be most interested in the bakery and confectionery department or in the book binding or shoe-making. All these, of course, are of great importance, and much good work is being done, but it should not be forgotten that on the scientific side which tends above all things to the nation's advancement, good work is being done with a rather difficult material and a small staff, the chemistry department being one of the very few in Great Britain which publishes research work.

THE question of education in relation to the British Empire was considered at a meeting held in the Guildhall London on Tuesday, under the presidency of the Lord Mayor. The following resolutions were unanimously adopted:—(1) That in the opinion of this meeting of citizens of London and others, the education of the people of Great Britain on the subject of the Empire is deplorably backward and that as an illustration of this fact it may be pointed out that no official map or text-book in regard to the Empire is available for teachers and the public; that in the opinion of this meeting the teaching of Empire subjects with the aid of official maps and text-books should be obligatory in all elementary and secondary schools in Great Britain and that the Government be requested to lend official assistance in the preparation of such maps and text books, and to sanction the permanent display of Empire maps in all schools post-offices, and public buildings (moved by the Duke of Somerset and seconded by Dr. Parkin). (2) That a public subscription for the purpose of Empire education be inaugurated, and that the aid of the London and provincial Press and of all societies and associations without regard to party politics be invoked to collect funds for the purpose; that copies of these resolutions be sent to the Government, all lieutenants of counties, lord mayors, and mayors throughout the country, inviting them to call public meetings and submit thereto similar resolutions, and appeal for subscriptions to the fund (moved by Lord Milner and seconded by Mr. Deakin). (3) That the fund be called the "Empire Education Fund," and that the first trustees shall be the Right Hon. Sir W. Treloar Lord Mayor, his Grace the Duke of Somerset, the Right Hon. Viscount Milner, P.C., G.C.B., G.C.M.G., the Right Hon. Sir Rowland Blennerhassett, Bart., P.C., and Mr. Allen H. P. Stoneham (moved by Lord Strathcona and seconded by Lord Ranfurly).

A CONFERENCE on the teaching of hygiene and temperance in the universities and schools of the British Empire was held in London on Tuesday. Lord Strathcona presided at the morning session and Sir John Gorst occupied the chair at the afternoon meeting. From the papers read it is clear that in several of our colonies and in some foreign countries much more attention is given to instruction in the laws of health than has yet been granted to it in this country. The chief object of the conference was to give prominence to this fact and to urge upon our educational authorities the importance of remedying the defect. Sir Victor Horsley, F.R.S., in an address on the method of introducing hygiene and temperance into secondary schools and universities, suggested that an

essential reform within the Board of Education is that there shall be such advice given to the Minister of Education as will enable him to grasp the principles of scientific education It is the business of the State to see that the code and curriculum of education are arranged on a scientific and common-sense basis, and this will necessarily include the hygiene of common life and instruction in temperance Sir Victor Horsley contended that we shall not make any headway unless we have expert advice at headquarters It is clear that the whole system of education requires revision from a medico-scientific standpoint The following resolutions were unanimously adopted —(1) "That this conference has heard with great satisfaction that instruction in hygiene and temperance is systematically given in the elementary schools of the colonies of the Empire, and that there is strong evidence of the value of this teaching While cordially acknowledging what has been already accomplished in the United Kingdom by certain educational bodies, this conference urges upon all local authorities the necessity of providing that the teaching of hygiene and temperance shall form an essential part of the whole curriculum of education of all children" (2) "This conference is of opinion that to meet adequately the responsibilities of the State towards school children it is essential that a medical department should be instituted in the Board of Education"

SOCIETIES AND ACADEMIES

LONDON

Royal Society, February 7—"On the Combining Properties of the Opsonin of an Immune Serum" By Prof Robert **Muir** and W B M **Martin** Communicated by Dr C J Martin, F R S

(1) The thermolabile opsonin of a normal serum and the thermostable opsonin of an immune serum are two distinct classes of substances In addition to differing markedly as regards their resistance to heat, they differ in their combining relationships

(2) The thermostable opsonin of the anti serum investigated is a true anti substance and possesses the comparatively specific characters of anti-substances in general, it is left undetermined whether it has the constitution of an agglutinin or of an immune body, though certain facts point in favour of the former

(3) Emulsions of other organisms other than the organism used in immunisation (*Staphylococcus aureus*) do not absorb the immune opsonin, on the other hand, they absorb large amounts of the normal complement like opsonin

(4) Powerful complement-absorbers—red corpuscles or bacteria treated with immune body or serum precipitate—have no effect on the thermostable immune opsonin whereas they remove almost completely the labile opsonin of the normal and the immune serum alike

Faraday Society, March 10—Dr T Martin Lowry in the chair—The potential of hydrogen liberated from metallic surfaces H **Nutton** and H D **Law** The paper is chiefly concerned with the chemical reducing power of hydrogen when liberated from the surface of various metallic electrodes, and also the retarding action caused by the presence of small quantities of metallic salts The metals are arranged in the following order—mercury, lead, cadmium, tin, silver bismuth gold nickel, platinum (black), the first mentioned metal being the most capable of bringing about the reduction of a compound not readily attacked, platinised platinum, on the other hand, possesses this property in the lowest degree Zinc as a reducer behaves in a very irregular manner, both copper and platinum (black) show a remarkable activity in the reduction of aromatic aldehydes, and iron and aluminium are variable It was hoped by a careful study of the electrode potentials that it might be possible to differentiate between the purely chemical changes and those which were due to physical causes—Electrode potentials in liquid ammonia N T M **Wilsmore** and F M G **Johnson** The measurements of electrode potentials in liquid ammonia were undertaken with a view to the determination of the free energy of formation of a series of metallic salts, and thereby to compare the relative affinities of the corresponding metallic elements under conditions differing as much as possible from those obtaining in the case of measurements in aqueous salutions To this end the electrode potentials of the metals against solutions of their salts of known strength were measured against a standard electrode (cadmium in a saturated solution of cadmium nitrate) The results are given in the paper in tabular form—The impedance of solutes in solvents as manifested by osmotic pressure J G A **Rhodin** The author's object is to substitute for the theory of van 't Hoff, the main objection to which, in his opinion, is the direction of pressure a theory which regards the solvent—and not the solute—as the source of the energy manifested in osmotic pressure experiments—The electrolytic deposition of zinc, using rotating electrodes, part ii Dr F Slater **Price** The effect of the addition of various electrolytes on the electrolytic deposition of zinc, using a rotating kathode and the apparatus described in the previous paper, has been investigated In all the experiments the kathode was silvered before the zinc was deposited Excellent results were obtained using 2 grams of sodium sulphate and 1 gram of sodium acetate for each gram of crystallised zinc sulphate, the addition of free acetic acid being unnecessary The number of revolutions per minute of the kathode was 600–700, and the time of deposition was fourteen minutes

Linnean Society, March 21—Prof W A Herdman, F R S, president, in the chair—The origin of Angiosperms E A Newell **Arber** and John **Parkin.** In attempting to trace the ancestry of this group the authors commence by a survey of living Angiosperms with a view to determine which among them present primitive features and also with the hope of arriving at some hypothesis as to the type of fructification possessed by the earliest members of the group They dissent emphatically from the view generally held and especially advocated by Engler that the most primitive Angiosperms to-day are those with unisexual flowers and without perianth e g Piperales Pandanales &c This conclusion is criticised on the grounds that (1) the perianth must be assumed to arise *de novo* and to be an organ *sui generis*, (2) such plants have a sharply defined and highly complicated inflorescence, which can hardly be regarded as primitive (3) it has so far proved barren from a phylogenetic standpoint On the contrary they urge the acceptance of a strobiloid theory of the angiospermous fructification on the grounds that it is typically and primitively a diplosporangiate (hermaphrodite) cone with a well marked perianth and one in which all the organs were originally numerous, spirally arranged, and hypogynous It is pointed out that some of these primitive features are still retained among members of the Magnoliaceæ, Ranunculaceæ Alismaceæ &c From such a cone the authors would derive by reduction the apetalous unisexual flowers The flower is recognised as a special type of strobilus to which the name Anthostrobilus is given and of which two forms can be distinguished, the one gymnospermic, the other angiospermic Both, however, are essentially of similar construction especially as regards the peculiar juxtaposition of the micro- and mega sporophylls and the presence of a perianth The view is expressed that the "motive force" which called the Angiosperms into existence, was a radical change in the method of pollination

Physical Society, March 22—Prof J Perry, F R S, president, in the chair—Experimental mathematics Mr **Pochin** An instrument for describing logarithmic spirals was exhibited and it was shown how the principal properties of logarithms and of the equiangular spiral may be established as experimental results A spiral was described with an angle of 45°, and the positions of the radius vector, representing the first ten natural numbers, were drawn in Cardboard sectors having been cut to fit the various angles under the successive positions of the radius vector, it was shown that these sectors represented the logarithms of the numbers Multiplication and division were illustrated by placing the sectors in juxtaposition, so that the angles were added or subtracted, the result being read off directly from the curve A table of natural logarithms was also prepared from the spiral, by direct

measurement with a foot-rule and a protractor graduated in radians. A geometrical analysis was given, confirming the accuracy of the experimental results, and affording an independent proof of the exponential theorem. A second spiral was drawn with an angle $\tan^{-1}M$, thus giving common logs. in terms of the radian, and it was shown that, by using a suitably graduated protractor or modulus, one system transformed into the other. A Boucher's circle and a slide-rule were also derived practically from the spiral. The differentials $d\log_e r/dr$ and $d\log_{10} r/dr$ were shown graphically, as well as the properties of the evolute and involute.—Logarithmic lazy-tongs and lattice-works: T. H. **Blakesley.** If two straight rods, AB, CD are jointed at E, and so related that the extremities ACBD lie in the circumference of a circle, they will fulfil this condition when the angle between is changed. Suppose that AE is taken as unity, and that ED=n, EC=m, m and n being quite independent. Then EB=mn as a consequence. If another pair of rods, DF, BG, similar to the first pair but bearing the ratio n : 1 to it, be jointed at D and B to the first pair, and to the extremities FG of this pair a third pair be again jointed, and a fourth to this and so on, the ratio of each pair to the preceding one being n : 1, the resulting linkage is called by the author a logarithmic lazy-tongs. A lazy-tongs constructed as above is said to be in the n direction. Any of the four sides AC, CB, BD, AD might be chosen as that to which the next pair of rods is to be attached, care being taken to make the ratio correspond to the direction chosen. If CB is chosen the ratio must be m : 1, and a lazy-tongs in the direction m will result, the angular shift at each step being EAD—EDA. Suppose pairs added in the m direction to both CB and BF, then these two pairs will have, in addition to B, another common point, viz. that which is homologous to B in the m direction. In fact, the same pair is arrived at whether by moving once in the n direction and then once in the m direction, or *vice versâ*. It is clear that a joint may be added at the common point and that the rule is a general one, hence all plane space may be occupied by such a linkage, which is called a logarithmic lattice-work. Such a lattice-work moves so that the angles at E, and points homologous will remain equal.

Geological Society, March 27.—Sir Archibald Geikie, Sec.R.S., president, in the chair.—The southern origin attributed to the northern zone in the Savoy and Swiss Alps: Prof. T. G. **Bonney.** Prof. Lugeon, with some other eminent Continental geologists, explains certain peculiar flat folds the higher of which sometimes project considerably beyond the lower, in the more northern sedimentary zone of the Swiss and Savoy Alps, by supposing that to no small extent the strata have been thrust forward from an original position south of the watershed of the Pennine-Lepontine Alps, overriding, as they advanced, their crest and that of the Oberland (neither having then attained its present altitude). This pressure was produced by the greater thickness of deposits of mid-Tertiary age, speaking in general terms. Prof. Sollas, in concluding a very interesting and suggestive paper on some experiments with cobbler's wax, published in the last volume of the Quarterly Journal of the society, p. 716, suggests that the results are favourable to the views of the Lausanne professor. The author takes exception to some of the cases, especially two to the east of the Simplon Pass, which are adduced by Prof. Lugeon in support of his hypothesis. It is maintained that the hypothesis receives no real support from Prof. Sollas's experiments, and involves mechanical difficulties which are practically insuperable.—The coral-rocks of Barbados: Prof. J. B. **Harrison.** The results of the author's extended, and in many places detailed, re-examination of the coral-rocks in the southern half of Barbados give no support to Dr. J. W. Spencer's theory of the existence of strata of the "Antigua formation" in that island. It is now shown that a certain knoll, whence Dr. Spencer collected corals which in his estimation proved that it and other parts of the coral-rocks were of Oligocene age, is in part made up of corals which, as stated by Prof. J. W. Gregory, "certainly show no evidence of any age greater than the Pleistocene." The author has failed to find any signs of the widespread formation, described in Dr. Spencer's paper as extending from Mount Misery to near Ragged Point, a distance of about eleven miles, and dipping south-eastward at from 12° to 20°.

Society of Chemical Industry, April 8.—Mr. R. J. Friswell in the chair.—Observations on cotton and nitrated cotton: H. **de Mosenthal.** This paper deals with the appearance of celluloses and nitrocelluloses in polarised light, their refractive indices and optical activity, as well as densities. Fourteen samples of nitrated cottons of different degrees of nitration, different solubility and viscosity, three samples of nitrated wood cellulose, and two each of nitrated ramie and flax, were examined. The appearance in polarised light was found to vary with the degree of magnification and the light used, fibres appearing differently when dry and when moistened. Various moistening liquids gave different results. The colours shown in polarised light under the same conditions seemed to be chiefly dependent on the material nitrated and the method of nitration, and they cannot be regarded as a function of the degree of nitration. The densities of celluloses and of nitrocelluloses examined were found to be higher than those recorded in text-books. The densities of the nitrated material in solution were also determined and found to be higher than in the solid state. Observations of the refractive index of nitrated cotton in solution gave results which were not concordant, and therefore determinations were made on transparent films of nitrated cotton, ramie, and flax. The refractive index of cellulose was found by examining denitrated films and then by placing fibres in a liquid of like refraction. Atomic refractions were applied to some of the proposed formulæ for cellulose, and showed that the cellulose molecule has no double bonds.

Entomological Society, April 10.—Mr. C. O. Waterhouse, president, in the chair.—Wet- and dry-season forms of Pierinæ: Dr. F. A. **Dixey.** Specimens were shown of Pierinæ belonging to the genera Teracolus and Huphina. The exhibit was intended to illustrate the fact that in species of which the wet-season phases were very distinct from each other, the corresponding dry-season phases often could only be discriminated with difficulty.—Forms of Osphya and concurrent species: J. **Edwards.** Five forms of Osphya were shown, together with certain other species occurring at the same time and place, and, having regard to gait and appearance, resembling them more or less closely. It was not suggested that these resemblances are protective. Attention was also directed to an important function of the hind-legs of the male, namely, to secure him in position at the time of pairing.—Antennæ-joints in Trachiscelis: H. J. **Carter.** A microscopic slide prepared to demonstrate that the antennæ of the genus Trachiscelis have eleven joints, and not ten as hitherto described.—Odonata collected by Lieut.-Colonel C. G. Nurse, chiefly in North-Western India: K. J. **Morton.**—The life-history of *Cydimon* (*Urania*) *leilus*: L. **Guppy,** jun. This paper was followed by a discussion on the migration habits and classification of the species.

EDINBURGH

Royal Society, February 18.—Dr. Robert Munro, vice-president, in the chair.—The coat colour in horses: Prof. J. C. **Ewart.** (1) The remote common ancestor of the Equidæ was probably of a reddish-brown (foxy-red) colour. (2) Horses prior to domestication probably varied in colour and consisted of (*a*) species adapted for a forest life, having dark yellow-dun coat, a broad dorsal band and stripes more or less distinct on the face, neck, trunk, and legs; (*b*) species like Prejvalsky's horse, adapted for a steppe life, having a brown yellow or reddish-brown coat, a narrow dorsal band, but only at the most vestiges of shoulder and leg stripes; and (*c*) species adapted for a life on the plains, having a light yellow-dun coat and, in addition to a narrow dorsal band, only faint vestiges of stripes on the legs. (3) Yellow duns belonging to different varieties may, when crossed, give rise to bay and chestnut as well as yellow-dun offspring. (4) Bays obtained by crossing yellow-duns may, when crossed with pure yellow-duns, yield black and chestnut as well as bay offspring. (5) Chestnuts derived from crossing yellow-duns may, when crossed with pure yellow-duns yield white and bay as

well as chestnut offspring (6) When crossed with a yellow-dun a white may yield grey roan and white-dun offspring. (7) A black, crossed with a yellow-dun, may yield either yellow-dun or black offspring —The geology of Ardrossan Dr J D **Falconer.** A brief description is given of the geological structure of the area in the immediate neighbourhood of Ardrossan, the suggestion being made that the Upper Old Red Sandstone and overlying volcanic series were folded over an anticlinal axis striking north west and south-east behind Ardrossan The petrographical characters of the Carboniferous lavas and intrusive rocks are described in detail Of the latter, the most important is the sill at Castle Craigs, more than half of which is composed of picrite This rock passes upward into hornblende-dolerite along the whole length of the sill The upper portion of the intrusion is fine grained and banded parallel with the upper surface, and is crossed by small pink felspathic veins The sill affords an excellent example of the differentiation of one and the same magma into a lower basic and an upper felspathic portion It is supposed to present considerable analogy to the banded peridotites and gabbros of Skye, and to differ from the Blackburn and Barnton picrites near Edinburgh, in which the differentiation took place entirely after intrusion

March 4 —Prof Crum Brown, vice-president in the chair —Algebra after Hamilton, or multenions Prof Alexander **M'Aulay** *This is a system resembling in its* generality the *Ausdehnungslehre* of Grassmann, but built on the lines of Hamilton's quaternions It differs from the *Ausdehnungslehre* in having only one method of multiplication The theory of the "linity," analogous to the linear vector function in quaternions or to the matrix in algebra, is developed in considerable detail, also the closely connected method of differentiation, which is based upon the properties of the generalised ∇ —Note on the change produced in the conductivity and density of lead wires by permanent stretching J A **Donaldson** and R **Wilson.** The experiments were carried out in the physical laboratory of Edinburgh University The results were negative, there being within the errors of observation no appreciable change in either the electric conductivity or the density —The dynamical theory of seismometers Dr C G **Knott.** Some account was given of the recent important results, both theoretical and experimental, obtained by Prince Galitzin in his discussion of the theory of the horizontal pendulum, and a general discussion of earthquake records, now familiar to all students of seismology, led to the conclusion that, except for small, comparatively rapid vibrations of the ground, the amplitudes of the records could not be regarded as reproducing the motion of the ground even to a first approximation —Temperature observations in the North Sea Prof D'Arcy W **Thompson** In this communication the author gave an account of methods and results which form a part of the second report of the North Sea Fisheries Investigation Committee The material which formed the basis of the investigation was obtained partly from regular observations made at lighthouses and on lightships, and partly from observations, furnished twice a day, by captains of passenger steamers From these, by graphical interpolation fair monthly means of water temperatures on the surface and at various depths were obtained Many interesting results were arrived at, especially with regard to the changes of temperature throughout the year and the range of annual change in different regions of the North Sea See the Blue book recently published by His Majesty's Government

March 18 —Dr R H Traquair, vice-president in the chair —The influence of temperature on the photo electric discharge from platinum Dr W Mansergh **Varley** and F **Unwin.** The experiments were made in air, in carbon dioxide, and in hydrogen, at pressures varying, in each gas from atmospheric pressure to a pressure of 0·0035 mm of mercury In air and carbon dioxide at atmospheric pressure the photoelectric currents decreased with increase of temperature up to about 400° C, after which they began to increase again The maximum diminution in current was about 80 per cent of the normal value The behaviour of these two gases was identical In hydrogen at this pressure, on the other hand, the currents steadily increased as the temperature was raised from the ordinary temperature of the air At the lowest pressure (0·0035 mm) the photoelectric discharge in each gas was found to increase when the temperature was raised from that of the atmosphere to 60° C Further increase of temperature up to 400° C produced no change in the photoelectric current When the temperature was reduced to the ordinary temperature of the air, the sensibility of the surface gradually diminished with time, falling to half its value in about twenty-four hours In all cases time was required for the sensibility to attain a steady value after any change in temperature —*Spirophyllum ferrugineum*, a new genus and species of thread bacteria D **Ellis.** This flat, leaf-like, spirally wound organism was discovered by the author in iron-water ditches about a mile from Renfrew The width varied from 1 μ to 6 μ according to age, and the length might reach 200 μ The multiplication was by means of conidia, which germinated Immediately after germination the organism had a slight motility but this soon ceased Before deposition of the iron the cell was semi transparent This new genus connects the iron bacteria, which at present are placed in the Chlamydobacteriaceæ, or thread-bacteria, with Spiromonas, a genus which must therefore be now included among the thread-bacteria —The functions of the Rolandic cortex in monkeys Drs W A **Jolly** and Sutherland **Simpson** The object of the experiments, which were carried out in the physiological laboratory of Edinburgh University was to delimit accurately the motor areas in the cortex cerebri of the monkey The method employed was a new one The cortex was stimulated by unipolar faradisation, and the areas were isolated by the use of vulcanite plates The sharp edges of these plates were inserted into the cortex to a depth sufficient to divide the grey matter without penetrating the underlying white substance It was shown that the movements of muscles resulting from stimulation of the ascending parietal convolution were due to spread of current to the ascending frontal convolution The motor centres in front of the fissure of Rolando and on the mesial aspect of the hemisphere were mapped out by application of the same isolation method —Hydrates in aqueous solutions of electrolytes Rev S M **Johnstone** The paper gave results of extensive series of observations of the elevation of the boiling point and lowering of the freezing point in strong solutions, with determinations of conductivities at 0° C and 99°4 C In most of the curves showing the relation between concentration and elevation per gram equivalent there was a minimum point, above which elevation per gram equivalent usually increased with concentration at a gradually diminishing rate The hydration of the molecules and ions of the solutions examined was discussed on the admittedly doubtful assumption that the ionisation could be roughly determined from conductivity data Freezing-point and boiling-point data were found to give very similar values of the extent of hydration, the deliquescent salts giving the higher percentage hydrations The number of molecules of water of hydration per molecule of solvent for a highly concentrated solution of a non-deliquescent salt was found in some cases to be much less than the number of molecules of water of crystallisation

PARIS

Academy of Sciences, April 15 —M A Chauveau in the chair —Primitive tuberculosis of the lung and of the bronchial and mediastinal ganglions, communicated to young calves by the ingestion of tuberculous virus of bovine origin A **Chauveau** A review of the author's communications on the subject of tuberculous infection of the lungs through the alimentary canal, with especial reference to the recent work of Calmette —The application to pyridine of the method of direct hydrogenation by nickel Paul **Sabatier** and A **Mailhe** At moderate temperatures (120° C to 220° C) pyridine is scarcely affected by this reaction less than 1 per cent being acted on The amine formed is shown with certainty to differ from piperidine the expected reduction product and may possibly prove to be amylamine If the reaction is allowed to proceed at higher temperatures ammonia and pentane are produced in considerable quantities —Contribution to the pathogeny of pulmonary anthracosis S **Arloing** and J **Forgeot** A controversial paper directed against the

hypothesis of Calmette, Vansteenberghe, and Grisez—Researches on ammonium Henri **Moissan.** The contents of a sealed letter deposited November 5, 1906 The presence of water is not necessary to the production of ammonium amalgam, since it can be produced by the interaction of sodium on the chloride or iodide of ammonium in liquid ammonia at $-40°$ C This reaction is, however, only possible in the presence of an excess of sodium If the excess of sodium be removed by repeated washings with a solution of an ammonium salt in liquid ammonia the so-called ammonium amalgam no longer exists An account is also given of the product obtained by the electrolysis of the double iodide of mercury and ammonia in liquid ammonia—Prof Witz was elected a correspondant for the section of mechanics in the place of the late Prof L Boltzmann—The form of the geoid in the neighbourhood of Sahel Algiers MM **Bourgeois** and **Noirel**—A new method of regulating X-ray tubes G **Berlemont.** The arrangement proposed consists of an aluminium tube which can be connected at will to either the anode or kathode The tube can be made either hard or soft in a few minutes—The determination of the limits of inflammability of explosive mixtures of ether vapour and air Jean **Meunier** The lower limit of inflammability is about 75 milligrams of ether per litre of air, the upper limit is about 200 milligrams of ether per litre—The reduction of magnesia by carbon Paul **Lebeau** Magnesia is reduced by carbon at the temperature of the electric furnace with the production of magnesium and magnesium carbide Both products are in great part destroyed by the action of the furnace gases which diffuse through the carbon tubes This gas contains much carbon monoxide, and it is known that magnesium reduces this gas with great facility—Sulphide of aluminium and its combinations with manganese and iron sulphides Marcel **Houdard** Sulphide of aluminium, which is irreducible at the high temperatures of the electric furnace forms with sulphide of manganese and sulphide of iron two double compounds Al_2S_4Mn and Al_2S_4Fe, a description of the properties of these two substances being given—A new chloride of tantalum C **Chabrié** The new chloride is obtained by the reduction of tantalum pentachloride with sodium amalgam Its composition is given by the formula $TaCl_2 2H_2O$, and an account is given of its chemical behaviour—A method of synthesis of non-substituted β-ketonic amides Ch **Moureu** and I **Lazennec** The acetylenic amides heated in alcoholic solution with a secondary amine best with piperidine, give good yields of the corresponding ketonic amides—The migration of compounds possessing smell in the plant Eug **Charabot** and G **Laloue** The migration of these products from the leaves during inflorescence is proved—The Lutetian in the Soudan and the Sahara R **Chudeau**

CONTENTS.

SUPPLEMENT TO "NATURE"

VIRCHOW'S LETTERS TO HIS PARENTS

Rudolf Virchow Briefe an Seine Eltern, 1839 bis 1864 Edited by Marie Rabl geb Virchow Pp xi+244 (Leipzig W Engelmann, 1906) Price 5 marks

IN an excellent and yet modest introduction to her father's letters, Frau Rabl expresses the opinion that they have "almost the value of an autobiography", in this she underestimates their worth, for even at the best an autobiography is but a picture drawn long after the early struggles are over, whereas we have here a picture painted as the events happened, and painted with a rare skill and uncommon intimacy, because it was not drawn for the public gaze, but for his father's eye Even had Virchow become, as was originally intended, merely a surgeon in the army, and had he remained as at one time he feared, simply a unit in the great average mass, these letters would still have a permanent value as an interesting record of student life in Berlin during the fourth decade of last century, but since they depict the struggles of youthful years which culminated in a triple triumph at the dawn of manhood they form indeed one of the most important contributions ever made to the study of great men Before his thirtieth year Virchow had overthrown a speculative pathology which regarded disease as a manifestation of humours of the blood, and by the application of the methods used in the more exact sciences and the use of the microscope replaced it by one which rested on a solid foundation of fact He had by then begun the study of the antiquities and people of his native province of Pomerania, by then he had thrown in his lot, at the risk of place and life, with the patriots who sought to curtail the autocracy of the crown and ameliorate the condition of the poor and oppressed He was a splendid fighter and he fought for truth and freedom in politics as well as in science

Virchow himself held the opinion that the key to a man's mental development was not to be found in a study of the outward events which everyone might see, but in an intimate knowledge of the inward events, which only the man himself could know But even when these letters have supplied us with a knowledge of both outward and inward events we are still at a loss to explain why it was that an only son of a small farmer in a Pomeranian village who received the orthodox education of an army surgeon, became the Virchow we known in pathology politics and anthropology Heredity scarcely helps us, his father with the best will in the world, only succeeded in continually mismanaging his small farm and was permanently in financial straits, his mother we can picture from a letter Virchow addressed to her while he was still a junior student in Berlin, in that he enjoins her to give over complaining of the hardness of fate—what she names fate, he says, is merely the result of human deeds—and advises her to cease confiding her domestic troubles to chance acquaintances Her love and meekness towards him were unbounded His uncle on his mother's side was an architect of some repute in Berlin, his uncle on his father's side laboured with success to improve the accoutrement of the Prussian soldier

The circumstances of Virchow's youth resemble very closely those of Ruskin, except that Virchow's father was a poor man Both were only children in both cases the father was the dominant partner and took elaborate pains to teach the child to observe, in both cases the children by the time they reached early manhood, had fixed their gaze on a universe while their fathers' eyes never strayed far beyond the village pump, with the natural result that the intimate relationships between father and son became sorely strained "Only you misunderstand me" the youthful Virchow writes to his father "if you think my pride and self-confidence spring from my knowledge, its blanks I know best, they spring from a consciousness that I desire better and greater things and strive more earnestly for a full and complete mental life than most men His father had accused him of being self-conceited egoistical, and wildly utopian Much of the correspondence relates to finance and clothes Virchow senior counsels the purchase of ready-made trousers, "everybody who knows advises me against them" replies his son—and the son always took his own way In his early student days he set his heart on a felt hat but managed to jog along by borrowing one until the spring came when the particular fashion of that year had declared itself and he had accumulated sufficient funds for the purpose of purchasing a new one "It is sad to think" he writes "that my whole future should hang on a seasonable fall of rain or a few weeks of good weather in the harvest" Virchow never forgot the little farm "How does the corn look?" he continually asks "are the meadows doing well?" Even when his name was known in all the capitals of Europe he promises his father to be home in harvest to give him "a hand with his potatoes"

Some years ago the writer of this notice inquired into the circumstances which led to young men taking up the study of medicine In seven cases out of one hundred the reason was found to be that medicine was the only means of livelihood open to them which gave an opportunity of continuing a study of the natural sciences especially botany and natural history That was the reason which led Virchow to the study of medicine, at school the natural sciences were the hobbies of his spare hours Things have changed since Virchow's day nearly all the men who occupied the chairs of chemistry botany and natural history were then trained for medicine, nowadays one may hope to make a livelihood as well as a hobby of them

One is surprised to find so little mention of Johannes Muller in these letters his was the master mind among Virchow's teachers He must reckon among his pupils all the men who made Berlin a

great medical centre—Du Bois-Reymond, Brucke, Haeckel, Helmholtz Henle, Remak, Schwann, and Virchow Virchow himself would be the first, in his maturer years, to acknowledge the debt he and all Germany owes to Muller A K

INORGANIC CHEMISTRY

Introduction to General Inorganic Chemistry. By Prof Alexander Smith Pp xviii+780 (New York The Century Co, 1906)

Systematic Inorganic Chemistry from the Standpoint of the Periodic Law By Dr R M Caven and Dr G D Lander Pp xix+374 (London Blackie and Son, Ltd 1906) Price 6s net

AMONG recently published chemical books, of medium weight, as the clothiers say, these two are worthy of particular attention, for they embody careful attempts to present chemistry in a somewhat new way, and they have, each of them, a distinct individuality

Prof Alexander Smith, of Chicago has already expressed his views on the whole subject of chemical teaching in a work reviewed in these columns a few years since and he has published a "Laboratory Outline of General Chemistry" which has many merits, and has received the compliment of translation into German We turned, therefore, to his present exposition of general inorganic chemistry with special interest and with considerable expectations This new book embodies an attempt to interweave as much of the theory and detail of inorganic chemistry as will provide a reasonable course for a student entering upon the study of chemistry at a university Prof Smith adopts the plan of developing the theory piecemeal so that

"no conception is defined and no generalisation or law is developed until such a point has been reached that applications of the conception and experimental illustrations, later to be related in the law have *already* been encountered and there is about to be occasion for further applications and illustrations of the same things in the chapters immediately succeeding"

This is a difficult plan to carry out thoroughly in a science where there is really no one clearly definable sequence of topics that is the most natural or logical, and where indeed the most elementary facts and most familiar phenomena will, if we like, provoke the most far reaching questions of theory But Prof Smith has met the difficulties of his task with great skill, and has given us a very judicious and well-balanced selection of the facts of inorganic chemistry with a body of theoretical information little less than is to be found in a fairly advanced work on physical chemistry In this last direction the author has gone much further than most writers of modern text books, and his exposition of principles is in many respects original in form, and for that reason all the more interesting The divorce between inorganic and physical chemistry is admittedly artificial, and no one can question that great gain to the study of inorganic facts is derived from the application of chemical dynamics and the doctrine of equilibrium The infusion of electrochemistry, accompanied by the doctrine of ionic dissociation, will not be so universally acceptable, but probably most chemists will consider the introduction of the new dualism entirely justified by the present state of knowledge

Whilst Prof Smith has skilfully handled the theoretical matters which he has introduced, we cannot help thinking that he has attempted rather too much, and that in some cases the compression of the treatment imposed by the limits of the book will leave the student in the possession of thin knowledge and vague ideas The part of Prof Smith's book that seems to the present writer to be the least satisfactory is the introduction (chapters i. to iv), and this is the more to be regretted as it may prejudice the reader at the outset and deter him from proceeding to the vastly better material beyond The fault that is to be found is one not uncommon in American books, though it is of Teutonic origin, it is the attempt to read into chemistry a kind of philosophical completeness and logical exactitude which it does not really yet possess The delimitations of an "abstract concrete science," the meaning of "explanation," the explanation that "a cause is a condition or occurrence which always precedes another condition or occurrence" "stochastic and formulative hypotheses," the review of iron and sulphur with a view to the distinction between chemistry and physics, these seem hardly fruitful topics

Nor do we think that Prof Smith is happy in his treatment of them On p 5 it is stated in leaded type that

"the most obvious characteristic of a chemical phenomenon is that all the physical properties of the substance alter, that this alteration is abrupt that, in fact the products are different substances that the recognition and study of such a phenomenon is accomplished entirely by observations of a physical nature"

Now is this true of so simple an occurrence as the heating of a piece of chalk? Where is the obvious and abrupt alteration of all physical properties?

Again, on p 32, the leaded statements distinguishing between an element and a simple substance are almost cryptic in their subtlety, besides being mere dogmas as applied to members of the argon family

These examples might be multiplied, but enough has been said to indicate an objection that will be felt, we venture to think, by most readers, in relation to this exceptionally valuable and interesting book It might be worth considering whether, if they are to be retained at all, these philosophic excursions should not be confined to an appendix

Drs Caven and Lander have written a compact work on inorganic chemistry from the standpoint of the periodic law, intended for students who have reached the last stage of their degree course It is entirely different in scope and style from the work just noticed, and it has its own very distinct merits. It will probably satisfy admirably the requirements of students who desire to knit up the "ravelled sleeve"

that usually results from two years of the most conscientious teaching of inorganic chemistry, no matter how, by whom, or to whom the teaching be administered. The book is condensed, but it is not dull, there is, in fact, a sort of grip about it which is decidedly sustaining. Many subjects of difficulty, such as the complex cyanides and the amines, are treated with much clearness and perspicuity and most new things in inorganic chemistry are well elucidated. It is really a work on systematic chemistry, a study of chemical compounds *per se*, detached from all the arts of man, a sort of comparative anatomy based on the periodic law. Judged from this point of view, and not as a work that purports to contain all that a degree student should know of inorganic chemistry, it seems to the present writer as good as any work that has been written with the same object, and a great deal better than most of them.

Very few mistakes have been noticed in reading the book, but the expression (p. 8), "the modified form of Gay-Lussac's law is Avogadro's law," would shock the author of the first book under notice, and it is certainly not felicitous. On p. 44 the hydrides of sodium and potassium are (in view of Moissan's work) unfairly denied the character of definite compounds, and on p. 202 nitrogen trioxide is said to dissociate completely into nitric oxide and nitrogen peroxide on evaporating. The authors propose and use the terms *basigenic* and *oxygenic* respectively for base-producing and acid-producing, and there seems to be some need for such words, it is certainly confusing to speak of the basic properties of oxygen and the basic properties of caustic soda.

ARTHUR SMITHELLS.

GEOGRAPHY FOR SCHOOLS.

A Progressive Course of Comparative Geography on the Concentric System. By P. H. L'Estrange. Pp. xii+148. (London: Geo. Philip and Son, Ltd., 1906.) Price 6s. net.

Philips' Progressive Atlas of Comparative Geography. Edited by P. H. L'Estrange. Pp. 148. (London: Geo. Philip and Son, Ltd., n.d.) Price 3s. 6d. net.

Stanford's Octavo Atlas of Modern Geography. Third edition. Pp. 104+50 maps. (London: Edward Stanford, 1906.) Price 25s.

THE very title of Mr. L'Estrange's book expresses an admirable idea. The graduation of geographical teaching in such a way as to adapt the matter to boys and girls of different ages, and yet to make it educational at every stage, and hence to present at successive stages tasks of gradually advancing difficulty, is admittedly one of the hardest and at the same time one of the most important problems which the teacher has to face. In his attempt to accomplish this task Mr. L'Estrange has produced a work on which a very great amount of thought and pains have been bestowed, with such a wealth of instructive maps extremely useful for teaching purposes, and of equally instructive pictorial illustrations, and with a text possessing so many valuable features, that it may be unhesitatingly and cordially recommended to every teacher of geography.

It is to be regretted, however, that one cannot feel the same confidence in recommending the book for the use of the pupils. Notwithstanding all that Mr. L'Estrange has succeeded in doing, notwithstanding the fact that he has made important contributions to the solution of the problem that he has set himself, it can scarcely be admitted that he has been quite successful in so mastering the store of information he has amassed as to lead the learner securely onwards in the manner he has designed. This results partly, it would seem, from the fact that he has never formed any clear conception of the function of geography as distinguished from geology. He gives us no definition of the subject, but opens at once with an account of the structure of the earth's crust such as is given by the geologist. The greater part of this account is, no doubt, also of geographical interest, but if Mr. L'Estrange had recognised the fact that geography and geology differ in their points of view, he would probably have given less importance to some and greater importance to other parts of his physical geography.

The main feature of Mr. L'Estrange's work is an attempt to graduate the subject in three stages, A, B, and C, the A stage suitable to the lower section of a school in which a boy may spend two years, the others to the higher sections. The boy is intended in each successive stage to go over the same ground, to gain additional knowledge and to exercise his thoughts on more difficult problems in the higher stages, but "all without overlapping or ill-ordered acquisition of knowledge." This plan is followed both in the text and the maps, and the manner in which it is carried out in the maps is one of the most important contributions the author has made to the accomplishment of his task.

The plan is in a large measure sound, but probably most teachers will be disposed to think that he has pushed the idea of covering the same ground at every stage too far. They will question whether some of the subjects dealt with are suited for the A stage at all, for instance, that of map projections, which is distributed in a very unsatisfactory manner over stages A, B, and C. This fault, however, can be remedied by the teacher himself reserving the entire subject for the C stage. It is a more serious defect where we find that a reference to a higher stage is necessary to the complete understanding of a lower one, or ideas suited only to a more advanced stage are introduced in the treatment of subjects quite proper to a less advanced stage. Thus on p. 12, after the consideration of the whole subject of running water, we are suddenly introduced in stage A to the conception of alluvial valleys, explained as "flat plains of rich soil deposited by rivers in their lower courses", yet in the general treatment of running water in the A stage there is no account of the formation of such plains, to understand which one has to consider an action (of a quite simple character) reserved for the C stage, while in the A stage of the general matter we are introduced to the very difficult conception of

a "graded river" It is still worse to meet with statements that cannot but tend to beget confused thinking on the part of the learner, as where we are told that "on a flat surface streams begin by cutting deep perpendicular-sided ravines as in the cañons of Colorado" (p 8, col 2), or where from the wording of the text, a boy would be led to believe that a river in subsiding after a flood deposits matter only along its banks (p 9, col 1), or where he is told (p 32, col 2) that "the length and direction of rivers [in Great Britain] are largely determined by the surface features," which ought to lead him to try to think what other circumstances may contribute to determining those things These points may seem trifles, but for the A stage more particularly it is essential that the statements should be strictly accurate and unequivocally clear More serious misconceptions are sure to be engendered by such statements as that "the circulation of the waters of the ocean brings warmth to the coasts of British Columbia and Western Europe" (p 18, col 2) That is quite true if we understand by the coast the mere line of contact of land and water, but boys and girls ought to understand and never forget that it is not true 6 inches inland Indeed, the whole of the important subject of temperature is very inadequately treated There is no systematic development and consistent application of the fact stated on p 16, col 1, that "movements of air naturally bring warmth to cooler regions or coldness to warmer," and the neglect of this, one of the most serious omissions apparently due to the failing to form a distinct conception of the function of geography, gives rise to other statements in the book that cannot but mislead

In the preface, Mr L'Estrange points out that in most of the maps in his book the projections adopted are such as show the parallels of latitude by straight lines For larger areas the projection most frequently used is the homalographic, which is indeed very good where comparisons of area are important, but is not satisfactory for wind maps, for which it is used in Plate 4, with the result that in the January map the arrows representing the direction of the wind over the Yellow Sea and the Sea of Japan will be read as indicating north-west winds if we refer them to the parallels of latitude, but nearly due north if we refer them to the meridians By Mr L'Estrange Mercator's projection is eschewed throughout, but in spite of its obvious faults, for wind maps there is none better

The coloured plates, sixty-nine in number, of Mr L'Estrange's book are now to be had separately under the title of Philips' "Progressive Atlas of Comparative Geography" They consist mainly of maps on each of which there are either names or references by means of letters and numbers printed in brown, blue, and red On the named maps the brown names are those which it is considered proper for the boys and girls in the A stage to learn, those in B learning also the blue, and those in C adding the red The maps with references are in other respects duplicates of the named maps, and are intended as test maps In addition, there are various climatological, commercial, and industrial maps and diagrams, all well executed for the purpose for which they are intended. The "Atlas," like the corresponding plates in the "Geography," is provided with an index on a simple and ingenious plan, only the nearest degrees of latitude and longitude marked on the map being given, with the bearing from the intersection of those lines. Thus Nagpur is entered 20 80 N W., meaning that it lies north-west of the intersection of 20° N, 80° E, a method which enables one to find the place on the map referred to with great ease. Unquestionably this "Atlas" is fitted to be extremely useful in schools

"Stanford's Octavo Atlas" is well known for its merits of handiness, of as much fulness as is compatible with its size, and as much clearness as is compatible with its fulness In this new edition the more important changes that have taken place on the map of the world since the last edition are indicated The difficulty of inserting new names on the maps might to some extent have been met by inserting them in the index, where the excellent plan is adopted of including more names than are to be found on the maps, so that those who use the atlas are at least enabled to fix the position of a place on the proper map, and thus see its relations to the places which are named thereon The fact is, however, that some names, such as Kotlass in Russia and Nelson in British Columbia, have already found a place on maps, but not in the index For a new edition it would be well to reprint this index, abandoning the present plan of giving no reference to the number of a map, but only the name of the country to which a place belongs Thus one gets the latitude and longitude of a place in Canada, then has to refer to the table of maps at the beginning, and, finally, to ascertain in which of the three maps of Canada there enumerated the place is to be found In reprinting the index the opportunity might be taken to insert all places omitted GEO G CHISHOLM.

PHOTOGRAPHY FOR COLLEGE STUDENTS.

Photography for Students of Physics and Chemistry, By Prof. Louis Derr Pp vii+247 (New York The Macmillan Company, London Macmillan and Co, Ltd, 1906) Price 6s net.

PROF DERR is hard to please He says that good handbooks of photographic manipulation are abundant, but they are apt to be unsatisfactory because their business is not to explain principles Of complete treatises there are also not a few, but in them the thoughtful student is likely to be "overwhelmed with an avalanche of detail and history"; and monographs are too highly technical and "confined to such limited portions of the photographic field that the desired information generally lies in the gaps between them." He has, therefore, endeavoured to prepare a volume that suffers from none of these disadvantages He may have suited his book to the needs of his students, but the result

to a stranger presents itself as a very uneven treatment of the subject.

While lenses have eighty-nine pages devoted to them, more than a third of the volume, all the various methods of silver printing are dismissed in but forty-four lines. We find that toning silver prints has fourteen lines devoted to it, platinum printing twenty-two lines and two equations, while the use of spoiled lantern plates by cleaning off the films and utilising the glass compares with the above important subjects with its twenty-nine lines The incompleteness of the consideration of some other subjects, such as halation and intensification, leads sometimes to statements that may convey a false impression We read, for example, that by continuing the development of an exposed gelatino-bromide plate "the image will gain steadily in density until all the silver present has been reduced, when of course the process ends"—a statement that even mere rule-of-thumb photographers know, often to their cost, is not true Here, as in one or two other cases, theoretical considerations seem to have misled the author with regard to facts In short, he does not seem at home in the treatment of what might be called the more strictly photographic parts of the subject

It is easy to discover the sections of the subject that the author delights in, and it is in these that the value of the book consists The chapters on lenses do not go deeply into the matter, but they are interesting and clear, and give those details that students want The representations of the light reflected from the glass-air surfaces of single, doublet, and triplet lenses, and a lens with four separate glasses, are novel as book illustrations and very instructive In the directions given for testing a lens for its defining power, the fact that commercial plates are not flat is very properly emphasised, but this fact is overlooked in the method given for testing a camera for "register" It is to be regretted that depth of definition is treated of in the orthodox manner, namely, only as it affects that part of the plate immediately adjacent to the lens axis In direct contrast to this, the author does not follow in the footsteps of most of his predecessors with regard to illumination, considering the effects of focal length and aperture only, but demonstrates exactly how the brightness of the image on the plate must fall off at a distance from the lens axis under even the best experimental conditions

The chapter on exposure shutters shows that the author is practically familiar with them He gives the main facts concerning them, and the methods that he has used himself in investigating their mode of action He gives a table, two and a half pages in length, of the distances that a body falls in each hundredth of a second for a distance fallen of from 2 feet to 20 feet This ponderous method of timing shutters is surely obsolete The rotating bicycle-wheel method is also described, as well as methods of investigating efficiency

Photomicrographs of the grain of plates that have been subjected to various treatments are a notable feature of the work C. J

THE FAUNA OF THE TAY DISTRICT

A Fauna of the Tay Basin and Strathmore. By J. A Harvie-Brown Pp lxxxvi+377, plates and maps (Edinburgh D Douglas, 1906) Price 30s

WITH the appearance of this handsome work the author has the satisfaction of having completed the tenth volume of "A Vertebrate Fauna of Scotland", and we have great pleasure in congratulating him on having progressed thus far with a task stupendous enough to have frightened any man from attempting Not that Mr Harvie-Brown has written the whole, or anything like the whole, of the preceding nine volumes On the contrary, he was associated at the commencement of his work with the late Mr T E Buckley, who contributed largely to several of the volumes, while the second volume—on the birds of Iona and Mull—was written by the late Mr H D Graham, and the late Mr H A Macpherson was joint-author (with the editor in chief) of the one on the fauna of the North-west Highlands and Skye The volume on Shetland is again, the work of Messrs Evans and Buckley Nevertheless, the burden of the work as a whole has been borne by Mr Harvie-Brown and if he live to complete his task the author of the present volume will have accomplished for the whole of Scotland what his coadjutor Macpherson did for "Lakeland", and this, too, in a style which few can equal and none surpass For Mr Harvie-Brown is not only an exceedingly careful and industrious investigator, who will never let go a trail until he has hunted it to the end, and will never rest satisfied until he has completely refuted a doubtful assertion, but also a writer gifted with the power of putting facts in a pleasant light and of interesting his readers (who we hope are many) from start to finish He is, in fact, both an accomplished and elegant writer and an enthusiastic and painstaking field-naturalist—a combination which can scarcely fail to produce attractive and trustworthy work, as it has done in the volume now before us

As to the importance of works of this nature—more especially to those who come after us—no words of ours are necessary With the exception of one of a dotterel on her nest by Mr C Kearton, and of a second of the Perthshire Museum, the illustrations in the present volume are by Mr W Norrie, and when this has been stated, any commendation would be superfluous

In two respects the author has been specially favoured by adventitious circumstances in the case of the present volume In the first place, the area of which he treats lies in the heart of that great bay on the east coast into which the estuaries of the Tay and the Forth discharge, and it is consequently one peculiarly favourable for the arrival of birds migrating or driven from the eastward That such is really the case is evident by a glance at the map of the spread of the little auk over Scotland, facing p lxxxv In the second place, Perthshire possesses a number of local observers specially interested in the fauna of the district, and likewise a museum entirely devoted (as it should be) to the illustration of the local natural history As examples of the richness of the avifauna

of the district, reference may be made to two lists of birds seen on single days given in the introduction. In the first of these the author records having seen from the road thirty-four species of birds during a drive in the Crieff district, while in the second no less than fifty-four are mentioned as having been seen by the Duchess of Bedford during a few hours' watching at Meikleour

In the matter of nomenclature the author sticks to the scientific names which have been so long in general use for British mammals, while in the matter of the limitations of genera he likewise follows the old-fashioned usage, retaining, for instance, the blackbird and the ring-ousel in the same genus as the thrush He will not even accept Microtus in place of Arvicola, for the water-rat and its relatives, while as to the proposal to adopt Myotis for certain bats, he will have none of it In one point, and one only, we take serious exception to the author's classification—namely, in his reference of the slow-worm to the Scincidæ in place of to the Anguidæ, of which it is the type

Were space available, nothing would please us better than to refer at length to many of the author's observations on birds and mammals; but editorial restrictions peremptorily forbid, so that we can mention only a few points

Two of the most interesting features in the book are the maps showing the recent spread and increase of the starling and the tufted duck in Scotland In the former case the map

"shows two distinctly different movements in dispersal of the same, or (?) closely related races of starlings one from the north and east (and possibly from Faroe also), and one by purely increase and extension from the south In the map of the tufted duck's nesting-dispersal the advance is shown of a species coming for the most part from the south by simple increase, but suggesting also more than merely a south-to-north direct increase and something of a possible arrival from the east, along the two very principal routes which are followed by migrants at the present day"

Is there, we wonder some general unsuspected cause connected with these and other recent colonisations?

Of equal interest are the observations with regard to the advent and spread of the squirrel in this and the adjacent districts The author might, however, have referred to the fact that the British squirrel is certainly a well-defined local race

In many cases, as we have seen the author has chronicled the steady increase and spread of birds In other instances, on the contrary, he has the melancholy task of recording their impending extermination "Meanwhile," he writes, for instance, "our ospreys are on the verge of despair, they are in anticipation of rapid and final extinction" Although he adds that the resources of civilisation may even yet come to their assistance ere the curtain is drawn The goshawk and the kite, although formerly abundant, now only linger on as stragglers Mr Millais, who had a pair from a keeper at Rohallion, writes that

"It is a pity he destroyed them, as they are probably the last pair that bred in the country. Rohallion, with its great craggy fir-woods, was to my knowledge the last stronghold of both goshawks and kites"

With this reference to the end of the kite and the goshawk as breeding species, we must likewise reluctantly bring to an end our survey of an admirable volume R L

GEODETICAL TABLES

Auxiliary Tables to Facilitate the Calculations of the Survey of India Fourth edition Revised and extended, under the direction of Colonel F B Longe, R E, by Lieut-Col S G Burrard, R E, F R S. (Dehra Dun Office of Trigonometrical Branch, Survey of India, 1906) Price 2 rupees

THE growth of the Indian Survey and the improvements that have been introduced from time to time are to some extent mirrored by the increase in size and usefulness of the tables, which the department find it necessary to publish The fourth edition of these useful tables "to facilitate the computation of a trigonometrical survey and the projection of maps for India," which fill a tolerably thick quarto volume, bears possibly the same relation to the modest first edition that the work of the survey of to-day does to the work accomplished some sixty years since In that first edition only seventeen tables appeared Each successive issue increased that number, till now we have no fewer than sixty nine tables and six appendices containing useful matter likely to prove of assistance to geographical explorers

This new issue and wider employment of tables tells also of the changes that have been made in the method of projection used in the construction of Indian maps In the olden time the projection was so arranged that while the central meridian of a map was a straight line, all others were curved and concave to the central meridian This was found to be inconvenient, especially when it was required to place two maps together so as to form a single map A modified polyconic projection, in which all the meridians are straight lines is now employed This system, introduced by General Walker, will in future be used for all maps on the scale 1 1,000,000 and larger scales

With regard to the tables themselves, they necessarily take the form that long experience has approved This is a sufficient answer to any criticism, but to those who have been accustomed to a different method of calculation it may seem strange to find the logarithms of numbers less than unity affected with a negative sign As doubts have lately been expressed of the superiority of the method employed in astronomical calculations, it is not unimportant to notice that so influential a body as the Indian Trigonometrical Survey prefers to retain the use of a negative characteristic There are not, however, many tables in which this peculiarity is required Many tables have reference to "Graticules of Maps," and give the sides and diagonals of areas varying from $\frac{1}{16}$ of a degree to four degrees, on such scales as are used in the department

In the meteorological tables, if one might make a suggestion, it would be to the effect that Loomis's coefficients for determining the differences of height with the barometer might have been superseded by the results of more modern investigations, such as those of Angot or Rykatchef. Applying what appeared to be more trustworthy values to the example quoted, a result was obtained which differed some fifty feet, or about three-quarters per cent., from that given. This discrepancy seemed too large, but some of it may be due to want of experience in the use of tables. It would be interesting to know what degree of accuracy has been reached in the determination of heights by means of the barometer, and what is the correct way of assigning an average temperature, moisture, &c., to the mass of the atmosphere between the two stations. A not inconsiderable error must be introduced by unknown variations of temperature, accompanied, as these may be, by possible inversions.

THE CENTRAL NERVOUS SYSTEM

Das Cerebellum der Säugetiere. Eine vergleichend anatomische Untersuchung. By Prof. Louis Bolk. Pp. 337, illustrated. (Jena: Gustav Fischer, 1906.) Price 15 marks.

PROF. LOUIS BOLK has risen far above the opportunity that the title of this work would seem to offer, and has written a book of quite uncommon interest. To this success several factors have contributed. In the first place his own labours and those of Profs. Charnock Bradley and Elliot Smith, to whom he makes due acknowledgment, have brought much new light and interest to the subject. Symptomatic of this triad advance is a new nomenclature of a somewhat unfortunately triune character, varying from simple numerals to idyllic descriptive terms.

In the second place, the author has stepped beyond the limits of rigidly specialised morphology, and has entered the arena of general science. His courage carries him beyond the assertion that morphology is of profound interest to the physiologist, into the statement that morphology is a high road, although a narrow one, to the elucidation of function. It is a bold theme, and has rarely been better emphasised, but in this case its application is obviously weakened by the morphologist's concentration on the value of mass. A knife, some spirit, and a plate, a pair of forceps and a jar or two, together form but a pioneer outfit with which to delimit the frontiers of function, or even of structure, in the central nervous system. A microscope and the methods of the histologist would have added marvellously to the data upon which such a theme might have been sustained. This notwithstanding, the enthusiasm of its sustentation has greatly added both to the interest of this book and to the value of the work on which it is based.

Many anatomists, for the convenience of description, have divided the cerebellum into a median portion, the vermis, and two lateral hemispheres. According to the author, the pursuit of convenience has here overclouded important facts. The cerebellum is primarily divided into an anterior and a posterior lobe, and it is only in the latter that there is any real distinction into mesial and lateral lobules. He has carefully examined the correspondence between the mode of growth of the cerebellum and this true lobulation, and concludes that the organ grows by expansion from a definite series of centres, and that these centres are in a large measure independent, as is shown by their relative behaviour in different mammalian cerebella. From this point Prof. Bolk advances with the postulate that the functional capacity of each domain must have the same independence. Further, since the function of the cerebellum as a whole is to play some part in the adequate performance of muscular movements, each of these centres must control some particular province of movement. From this it is but a short step to the allocation of function. Symmetrical movements are controlled from mesial centres, asymmetrical movements from lateral centres. The more anterior the muscles involved the more anterior the centre. It therefore follows that the anterior lobe is concerned with movements of the head, eyes, tongue, jaws, larynx—all parts in which symmetrical movement is the most common. In the posterior lobe the first centre is also a mesial one, and controls the neck. Then follow both mesial and lateral centres for the control of the limb movements, and so on.

This method has at least induced the author to make most interesting comparisons between the cerebella of different mammals. When the animal's mode of progression is a symmetrical one, the lateral limb centres are small, the mesial large and complicated; when asymmetrical the relation is reversed. Where, as in the giraffe, the neck assumes a new importance, there is a coincident expansion of an appropriate mass in the cerebellum. In ruminants—but this is not quite so certain—there is an appropriate enlargement of the jaw-centre in the anterior lobe.

Now there is much probability in the idea that definite portions of the musculature are primarily connected with appropriate districts of the cerebellar cortex. Nerve-fibres ascending from the medullary nuclei doubtless enter the cerebellum as definitely marshalled as are their precursors in the spinal cord. It is extremely likely that outgoing fibres leave it no less well arranged. Most probable, too, is the idea that fibres from cephalic districts are distributed to anterior portions of the cerebellum. The crude forms of experiment which have up to the present been made available, may even for some time prove no more than this. It is certainly, therefore, to the credit of Prof. Bolk to have arrived at similar ideas by means of his, unfortunately also crude, methods of observation.

When the full meaning of the cerebellum is discussed, there is, however, a demand for evidence of a somewhat different kind. We have acquired a taste for the kind of evidence that Prof. Sherrington has brought to bear upon the function of the spinal cord. This is the attitude of Prof. Bolk, and it is a wise one. The elongation of the giraffe's neck is, as he

himself points out accompanied by more than an added complexity in the movements of this particular district There is a new "figure" to equilibrate It might also be suggested that there is something new in the location of eyes and semicircular canals at the end of so long a flail

No one interested in the central nervous system can read Prof Bolk's book without attention or without criticism J S MACDONALD

PARTIAL DIFFERENTIAL EQUATIONS

Theory of Differential Equations By Dr A R Forsyth F R S Vol v pp xx+478 vol vi pp xiv+596 (Cambridge University Press 1906) Price 25s net

THE appearance of these volumes marks the happy conclusion of a work undertaken as the author reminds us in his preface twenty one years ago Doubtless it would have been finished earlier had it not been for unavoidable interruptions but the delay must have brought its compensations because many most interesting developments are of recent date

Vol v deals with equations of the first order and immediately suggests two reflections one that Lie has made the most important contribution to the subject since the publication of Jacobi's memoirs and the other that it is a great help to have such an out line of Lie's theory with Mayer's simplifications as that given in chapter ix The Jacobian theory too with Mayer's developments is given in chapters iii iv in a very attractive and readable form Chapters vi vii viii are mainly concerned with characteristics and embody much of the work of Cauchy Monge Lie and Darboux as well as original contributions by Prof Forsyth himself

It may be a rather far fetched comparison but there does appear to be a kind of analogy between the achievements of von Staudt and Lie Von Staudt's treatise on projective geometry does not contain a single diagram but it is beyond question the most masterly work on the subject Lie is almost if not quite as chary of graphical illustration but the spirit of his work is geometrical throughout and he stands in the same sort of relation to Monge that von Staudt does to Steiner It is most interesting to see how the canonical equations of dynamics (pp 398–406) are illuminated by the theory of contact transformations and again it is mainly Lie's ideas which have prepared the way for a thorough discussion of *all* the solutions of a partial differential equation including the special integrals which do not come into the ordinary classification

The great advance which has been made arises from considering a differential equation not merely as representing a property of a function assumed to exist but as defining an aggregate of elements which are most vividly realisable in a geometrical form In partial differential equations of the first order these elements may be taken to be tiny fragments of planes scattered about in space the differential equation defines the system of elements, and a complete integral, if it exist represents the collecting of the elements into surfaces, which form a family In Clebsch's treatise on geometry there is a chapter on connexes to which he evidently attached importance, and which has obvious relations not only to mixed concomitants but also to ordinary differential equations. If it has not been already done, it might be worth while to see whether something might not be made out of these relations Clebsch's work has, of late, rather suffered neglect Again, it may be suggested that in dealing with partial differential equations of the second order it might be helpful to associate with given values $(x\ y\ z\ p, q\ r, s, t)$ a fragment of a surface of the second order just as a fragment of a plane is associated with $(x\ y\ z\ p, q)$. That fragments of this kind are less likely to be associable so as to form surfaces than corresponding plane elements is tolerably plain and partly accounts for the increasing difficulty of treating equations of the second order without making particular assumptions.

Vol vi of the present work is practically devoted to partial differential equations of the second order Thus we have chapters on Laplace's linear equation, with the elegant developments of Darboux, Moutard, and others the methods of Monge Ampère Boole, Darboux Hamburger &c with instructive comparisons and examples worked out each way, together with a chapter on general transformation embodying the most important of Backland's results As an example of the power of Lie's methods even in the production of beautiful *particular* theorems the proposition on p 295 may be quoted —

> When an equation of the second order (of the Monge-Ampere form) has two independent intermediate integrals it is reducible to the form $s=0$ by contact transformations

Very little comparatively has been done for equations of order higher than the second Prof Lloyd Tanner is one of the few pioneers in this region, and his results obtained by a different method are explained in chapter xxii

Prof Forsyth explains in his preface and final remarks the principles which have guided him in his choice of material This must indeed have been a most difficult task It would be easy to dub this treatise encyclopædic but it is not and the fact that it is not is one of its merits The literature on ordinary linear equations alone which has been published since Fuchs's memoir appeared in *Crelle's Journal* would much more than fill the whole of Prof Forsyth's pages No one who is not prepared to devote the whole of his time to the subject can possibly become familiar with all that has been written about it, and even if as is quite possible, this treatise may occasionally disappoint those who consult it on some subsection of the subject in which they are specially interested it is sure to be of great service by presenting an ordered and not unwieldy body of doctrine together with suggestions of the directions in which further progress may be expected.
